CHEMICAL ABSTRACTS

Vol. 22. NOVEMBER 10, 1928 No. 21

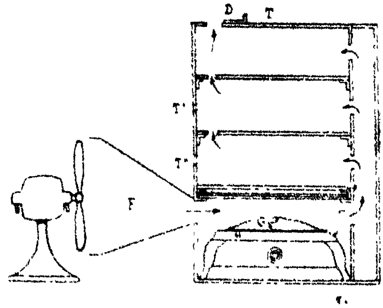
1—APPARATUS AND PLANT EQUIPMENT

W. L. BADGER

Laboratory evaporator. P. OERTEL. *Chem.-Ztg.* **52,** 302(1928).—A steam-heated evapg. bath is described which may be worked at pressures from about 0.2 to 0.5 atm. The mean temp. is 85° and the max. 95°, so that spurting or overheating of the material is avoided. The app. is so designed that little corrosion takes place and that the soln. which is being evapd. cannot be contaminated with products of the corrosion of the bath. B. C. A.

Rapid evaporation at room temperature. E. JANTZEN AND H. SCHMALFUSS. *Chem. Fabr.* **1928,** 373–5, 390–2.—The principles involved in the construction of a high-capacity lab. evaporator (40 l. of water per hr. at 15°) are discussed in detail. To attempt to remove water vapor by simple pump action is very uneconomical. It is better to use a water-jet pump with a condenser. The connection from the pump to the app. must be as short and wide as possible. A multitubular Cu condenser is far more efficient than one of glass. The connection from the evaporator to the condenser should be as wide as possible without any baffling arrangement to prevent splashing, which is guarded against by the low gas velocity and slight pressure drop. The still should be of simple construction of steel, Cu or Al. An app. of 30 l. still capacity constructed on these lines is described. B. C. A.

An effective laboratory drier. R. NEWTON AND W. H. COOK. Univ. of Alberta. *Plant Physiology* **2,** 359–60(1927).—The accompanying diagram is a vertical section of the drier. A galvanized iron box is lined with asbestos sheeting. The shelving and perforated partition shown at the right of the diagram are made of asbestos slate (transite) held in place by light angle-irons and stove-bolts. A rapid air draft is provided by a 9-in. desk fan blowing through the funnel *F*. The path of the air is indicated by the arrows. The air passes across *H*, an elec. hot-plate, into a narrow chamber to the right, from which it enters the drying chamber through 5 circular openings, 1.5 in. in diam., opposite the space above each shelf. The second and third shelves do not run the full width of the drying chamber, but leave an air gap at the left, bridged by light metal pieces (not shown in the figure). A set of air-holes at the top left is fitted with a damper *D* for controlling the draft. The shelf space is 14 in. square, with 4.5 in. between shelves. With the draft full open and the hot-plate turned to "high" (1000 watts), the temp. of the drying chamber was 61–63°. Thermometers are inserted at *T*, *T'* and *T"*, to check the various shelves. To secure the same temp. on all the shelves, it was found necessary to protect the bottom shelf with 2 extra layers of asbestos sheeting, and also to cut down direct radiation by 2 layers of wire gauze *G* over the hot-plate. The narrow chamber to the right is permanently closed in front by the wall of the box. The drying chamber is closed by a glass door, and the hot-plate by a piece of transite contg. an opening for the switch. Over both the latter is fitted an outside door of galvanized iron. The drier has been found satisfactory in speeding up the evapn. of aq. exts. to dryness and for the rapid drying of green plant tissues for analysis. WALTER THOMAS



A small washbottle. C. SHELDON HART. Syracuse Univ. *J. Chem. Education* **5,** 978(1928).—A "Y"-tube passes through a stopper in a small flask, or is connected to the flask by a piece of rubber tubing. Through it a long nozzle-tube passes vertically to the bottom of the flask, being held in place by a small piece of rubber tubing. The

overall height should be kept at a min. and both mouthpiece and nozzle should be as short as possible. W. C. EBAUGH

Drying vessel. A. OPPÉ. *Chem. Fabr.* **1928,** 241.—A vacuum-tight drying vessel capable of being weighed consists of a cap making an external joint on to the vessel, the vessel itself, an upright cylinder, and top and bottom gas connections, the latter forming a spiral on which the vessel rests. The vessel is particularly intended for bulky hygroscopic substances and is adapted for use in a heating bath. B. C. A.

A simplified barometer. H. C. KREMERS. Univ. of Illinois. *J. Chem. Education* **5,** 1004(1928).—A base-board has a wide slot milled out to accommodate a meter stick so that the 2 surfaces are flush, a friction spring holds the meter stick in any position, and the lower end of the stick holds a double pointer, one behind and one in front of the barometer tube. The latter is of the ordinary siphon type, not graduated. The meter stick is set level with the Hg in the lower column (as zero), and a sleeve around the upper part of the barometer tube is made level with the Hg there. The height of the Hg is thus read with ease, and students have little difficulty in understanding the principle involved. A simple set of directions mounted beside the barometer has provided ample guidance to the student using it. W. C. EBAUGH

The history of the Bunsen burner. HEINRICH BILTZ. *Z. angew. Chem.* **41,** 112(1928).—Feldhaus (*C. A.* **22,** 335) states that independently of Bunsen and at about the same time (1851, 1854) R. W. Elsner invented a burner like that of Bunsen. However, a burner in which air was mixed with gas to prevent soot formation was described by Faraday in 1828. Thus the principle of the Bunsen burner goes back to Faraday; to Bunsen belongs the credit for its present form. E. H.

Automatic temperature regulators and their value in laboratory and commercial processes. J. COURNOT. Conservatoire national des arts et métiers. *Chimie et industrie* **Special No.,** 141–7(April, 1928).—A discussion of the advantages of automatic temp. regulation, with a description of the chief types of regulators at present on the market and of the principal methods of using them. A. PAPINEAU-COUTURE

The standardization of thermometers. H. HEINRICH. *Arch. Wärmewirt.* **9,** 193–5(1928).—An account of a study designed to improve certain types of German armored industrial thermometers. ERNEST W. THIELE

A new receiver correction thermometer for the receivers on stills for high percentage spirits. ANON. *Apparatebau* **40,** 195–6(1928).—A correction for percentage is printed on the scale opposite each degree from 5° to 30°. J. H. MOORE

Calorimeter for determination of heats of combustion. A. EUCKEN AND L. MEYER. *Chem. Fabr.* **1928,** 177–9, 195–6.—The app. comprises a heavy hollow Cu cylinder (250 cc.) with Cu lid, carrying the usual ignition app. terminating in a thin Ni wire. The material to be burnt (30–40 mg.) is mixed with 6–8 mg. of kieselguhr and pressed into a small briquet which is placed in a conical silver wire cage in the calorimeter and burnt in O under atm. pressure. The temp. is recorded to the nearest one-thousandth of a degree every 1/2 min. until const. A series of results showing the range of utility of the app. is given. B. C. A.

Gas calorimetry. M. BARASH. *Ind. Chemist* **4,** 336–7(1928).—The Thomas Recording Gas Calorimeter, as designed by the Cambridge Instrument Co., has now reached such a stage of perfection as to be accurate to ± 1 B. t. u. The instrument is now especially well adapted to become the official recording calorimeter to be employed in the administration of the Gas Regulation Act of 1920 which placed the supply of gas to the English public on a calorific basis (the "therm"). E. G. R. ARDAGH

Automatic colorimeter. G. BAGANZ. *Chem. Fabr.* **1928,** 358.—The app. is designed for the control of the chlorination of town's water by the use of benzidine and KI as colorimetric indicators, but is capable of adaptation. It consists of an elec. arrangement for the taking of samples, addn. of indicators and washing out of the app. at regular time intervals, the observation only being left to the attendant.
B. C. A.

New microcolorimeter and its use. H. KLEINMANN. *Chem. Fabr.* **1928,** 263–4, 278–9.—The colorimeter is similar in principle to the Duboscq instrument and consists of a pair of vessels of 1 cc. capacity, dipping rods, lamps, scales and eyepiece. For accurate results careful filtration of the solns. is necessary and air bubbles must not be allowed. Errors then should not exceed 1%. The instrument is suitable in conjunction with a micro-Kjeldahl app. for the detn. of N by Nessler reagent. Quantities as small as 5×10^{-6} mg. can be detd., the principal difficulty being not of manipulation, but in obtaining reagents sufficiently free from NH_3. B. C. A.

Calibration liquids for viscometers. D. KRÜGER. *Z. angew. Chem.* **41,** 375 (1928).—Castor oil and glycerol are not recommended for calibrating capillary viscom-

eters as they are liable to changes, the former under the influence of air and light and the latter on account of its hygroscopic nature. Solns. of sucrose in water, up to 60%, give the best results, and the abs. viscosities, in centipoise units for such solns. at different temps., are tabulated. B. C. A.

Apparatus for the analysis of solutions, especially bleach liquors containing chlorine. K. Hintzmann. *Chem. Fabr.* **1928,** 266-7.—To det. the available Cl in a bleach liquor an app. comprising a graduated tube with a lower reaction bulb and an upper stoppered bulb holding 75 cc. of liquid is used. The reaction bulb is filled with 75 cc. of a standard soln. of indigo-carmine (1.46 g. of the 44/45% powder and 2 cc. of H_2SO_4 per l.), the stopper placed in the upper bulb, the app. inverted and the buret read. The whole is turned back to the normal position and the soln. to be analyzed is added slowly until the color of the mixt. changes from blue to light yellow-green The stopper is replaced, the app. inverted and the buret again read to obtain the amt. of bleach liquor added. B. C. A.

Apparatus for carrying out filtrations, precipitations, etc., in absence of air. P. Dickens. *Chem. Fabr.* **1928,** 323-4.—A conical flask with side tube closed by a glass tap and narrowed at the top is united by a funnel to a similar but inverted flask. Suitable ground-glass joints are provided for the funnel B. C. A.

Manometer for vacuum distillation. F. Friedrichs. *Chem.-Ztg.* **52,** 272(1928).—A manometer which is independent of atm. pressure and can readily be filled with Hg and freed completely from gas and moisture comprises the usual open and closed parallel tubes enclosed in an outer closed protecting tube, and connected to each other through a small valve on the injector principle. To fill the manometer Hg is poured into the open tube, and the closed tube is heated in an inclined position until the air is displaced and the Hg boils gently. The manometer is then filled with Hg until the metal reaches to the cylindrical part of the open tube, when the app. is ready for use. B. C. A.

Extraction apparatus especially suitable for liquids. P. H. Prausnitz. *Chem. Fabr* **1928,** 324-5.—A continuous extractor can be used equally as well as a Soxhlet app. even when of considerable cross-section if the condensed extg. liquid is prevented from falling in one place. This is effected by widening the lower end of the condenser and drawing it out into a large no. of points Extn. is more rapid than with a Soxhlet app. The same device is applied to Wagenaar's app. for extg. a solute from a lighter liquid with a heavier one. A glass filter is of no use as a distributor in these 2 cases, but is serviceable in the extn. of a heavier liquid with a lighter one. B. C. A.

Extraction apparatus especially for use with liquids. P. H. Prausnitz. *Chem. Fabr.* **1928,** 346-7.—The use of a perforated glass filter, in the extn. of aq. solns. with ether, in the bottom of the extn. tube is of great value in producing effective distribution. The extn. tube should be cylindrical and the space beneath the filter plate as small as possible. Several different arrangements of extn app. are described and times required for complete extn. of a given soln detd. B. C. A.

Apparatus for the determination of carbon by the baryta method. P. Dickens. *Chem. Fabr.* **1928,** 293-4.—The $Ba(OH)_2$ is contained in an absorption tube with a glass filter plate at the bottom above the gas inlet The restriction on the passage of the gas causes the combustion tube to be under pressure during operation, while the app. is previously swept out with pure O. Above the tube is a filter and flask so arranged that after combustion the app. may be inverted and the $BaCO_3$ filtered and washed with water free from CO_2. The excess of $Ba(OH)_2$ is titrated and the pptd $BaCO_3$ weighed as $BaSO_4$ The method gives results accurate to $\pm 0.001\%$. B. C. A.

Precision gas buret for volumetric determination of carbon. Oskar Meyer. *Chem. Fabr.* **1928,** 520-1.—The app. is designed for the *detn. of C in Fe and steel* and is so constructed that the vol. of CO_2 is cor. for temp. and pressure and the % C read directly from a scale accurate to 0.002%. J. H. Moore

Method of determination of melting point with electrical signal. G. Wick and G. Barchfeld. *Chem. Fabr.* **1928,** 281.—The substance is packed in the bottom of a glass tube and above it rests a narrow glass rod on which rests a contact arm. The tube is placed in a heated block and when liquefaction occurs the rod and arm fall, closing an elec. circuit. B. C. A.

Apparatus for the determination of the molecular weight by the boiling-point method. H. Rupe and Natala Wassilieff. Anstalt für organ. Chemie, Basel. *Helv. Chim. Acta* **11,** 713-6(1928).—A modification of the app. of Washburn and Read (*C. A.* **13,** 1172) is described. The new device is simpler and less expensive. It has been used with Me_2CO, C_6H_6, $CHCl_3$ and H_2O as solvents; the mol. weights were obtained within about 5%. A. L. Henne

Apparatus for sampling powdered solids. J. von Meerscheidt-Hüllessem.

Chem. Fabr. 1928, 357–8.—A four-sided pyramid of sheet iron standing upright is provided with wings on each angle so as to direct material sliding down each face into a sep. container. A funnel-shaped container above the pyramid is held centrally above its axis by a wooden staff which also closes the bottom of the funnel, and the whole is encased in a cylinder. The funnel is filled with the sample to be reduced, and the wooden plug lifted when the sample is automatically "quartered." B. C. A.

Centrifugal mixers. E. Buhtz. *Chem. Fabr.* **1928**, 211–3.—Several types of mixers are described, the essential feature being that the 2 liquids, or the liquid and solid, to be mixed are fed continuously on to a rapidly rotating dish, over the edge of which the finished mixt. passes. Provision is made for heating the dish and inlet pipe, for removal of gases evolved, etc., as necessary. Their use is suggested for the *acid treatment of crude oils*, the *salting out of soaps* and the *refining of fats*. In some cases spiral baffles are provided. Another type of app. has an upper rotating plate and a lower funnel-shaped dish with common axes revolving in opposite directions. This is intended for the mixing of colors, moistening of powders, etc. B. C. A.

A mechanical agitator. G. N. Quam. Coe College, Cedar Rapids, Ia. *Ind. Eng. Chem.* **20,** 908(1928).—An agitator (20 × 35 × 14 cm.) is illustrated. It has 6 test tubes (2.5 × 20 cm.) placed along opposite sides, each tube with a stopper and breather outlet. The agitator floats in a H_2O thermostat and can be rocked through 30–35°, thus causing the test liquid to flow over the metal strips (7.5 × 4 cm.) folded up and inserted in the tubes. Thus for raw whole sweet milk metals showed the following approx. losses when heated to 75° for 30 min.: Cu 1.38–1.72, Zn 0.68–1.03, Ni 6.02–6.71 and Sn 0.0–0.17 mg./sq. dm. W. C. Ebaugh

An apparatus for the measurement of radiation intensity over a wide range of wave lengths (0.02-3 A. U.). Otto Glasser and V. B. Seitz. *J. Optical Soc. Am.* **17,** 240–7(1928). E. H.

Spectrocomparator. F. Stanley. *J. Optical Soc. Am.* **16,** 208–10(1928).—A comparator, which enables 2 spectra taken on different scales to be compared directly, is described. The optical system is arranged to give different magnifications in the 2 fields, and the eyepiece carries a micrometer. B. C. A.

A microphotometer for comparative measurements of density on x-radiogram spots. K. V. Vasil'ev. *Trans. Inst. Econ. Mineral. Met.* (*Moscow*) No. **34,** 16–19 (1928).—A microphotometer, consisting of 2 identical microscopes, (made with an eyepiece, a Lummer's cube and 2 adjustable object-glasses), a source of light and a means for mounting the x-ray photograph to be examd. and a photographic wedge, is described. The microscopes are focussed on the wedge and film, resp., and then adjustment of the wedge is made until images of the wedge and spot are indistinguishable. The central portion of the image at the eyepiece is the image of the examd. spot and its extent depends upon silvered area in the Lummer's cube. The outer portion is the image of the photographic wedge. R. L. Hershey

A simple camera for obtaining oriented Lauegrams. K. V. Vasil'ev. *Trans. Inst. Econ. Mineral. Met.* (*Moscow*) No. **34,** 26–35 (1928).—A simple Laue camera consists of a lead-covered box, provided with a lead slit system, and a set of spring clips for holding the plate. The specimen, in the form of a crystal plate of known orientation, is held by a spring clip against the flat end of the slit system. R. L. Hershey

A new electrophoresis cell. Melvin Mooney. *Phys. Rev.* **29,** 218(1927).—A new cell consisting of a complete hydrodynamic circuit is described. The lower half of the loop is a long 0.7 mm. capillary tube, with thin walls to permit microscopic observation of the colloidal particles within. The upper half, filled with distd. H_2O, is a short 12-mm. tube and has, therefore, a small hydrodynamic resistance. Hence the H_2O moves through the capillary with uniform velocity over its cross-section, the compensating reverse flow occurring in the large tube. The advantages are: the correction applied to the observed velocity of a colloidal particle to obtain its velocity relative to the H_2O is no longer subject to errors in locating the particle in the tube; the endosmotic velocity of the H_2O is generally opposite and approx. equal to the electrophoretic velocity. Hence the arrangement is suitable for precise measurement of 2 differences in mobility of different particles or of the same particle under different fields. R. L. Hershey

Applications of a new ebullioscope. Wojciech Swientoslawski. *Roczniki Chem.* **7,** 516–33(1927); cf. *C. A.* **13,** 1172; **18,** 777, 2444; **19,** 2427; **21,** 1398, 2821, 3532; **22,** 514; W. Daniewski. *Dissertation,* Polytechnic School, Warsaw.—Several gradually improved modifications of Washburn and Read's ebullioscope are described. A final "*differential*" model consists of a flask of 200 cc. (*A*), with a side tube for filling and 130 × 5 mm. neck through which the liquid is carried into a tube *H*, 130 ×

30 mm. There it flows down a fused-in 60 × 18 test tube filled with Hg into which a Beckmann thermometer dips. It measures the temp. of the soln. The solvent vapors rise through a 12 mm. wide side-tube to a tube *B* which differs from *H* only in that it carries a reflux condenser. It measures the b. p. of the solvent. The test tubes are surrounded by glass coils to facilitate the down-flow of the condensate. *H*, *B* and condenser siphon back to *A*. All connections are fused on. The accuracy of measurements is ±0.0015° to 0.002°. When connected with a manometer and kept at a const. temp. the app. (a simpler one-tube model) gives changes in *pressure* with an accuracy of 0.03 mm. This *ebullioscopic barometer* (*I*) is used for the detn. of *atm. pressure*. It served for the detn. of the deviation of *cane sugar solns.* from Raoult's law. The *standardization* of a *thermometer* gave 1.038° per 1° instead of the 1.039° given by the Physikalisch-technische Reichsanstalt. For the detn. of the b. p. of pure liquids and mixts. the b. p. was detd. in one ebullioscope, while in another water was kept with the aid of a pump under such a pressure as to make its b. p. identical with the liquid under 1 atm. It was thus demonstrated that *benzene* did not have 2 fractions with identical b. p. The b. ps. found were: 80.161, 80.171, 80.175 and 80.185°. *I* also permits the direct detn. of dp/dt from simultaneous readings of t and p and the calcn. of the *heat of evaporation* from these values. It was detd. for a no. of esterification mixts. by S. and E. Józefowicz. (*Dissertation*, Polytechnic School of Warsaw). The *equil. const.* of *acetylation of EtOH* was detd. by placing in 1 ebullioscope AcOEt + water and in another AcOH + EtOH and connecting both with *I*. From the b. p. of the mixts. near equil. *K* was calcd. to be 3.68 in accordance with E. Dobbin (Dissertation, Brynn Mawr, 1920). The *K* for the vapor phase was found with a slight modification to be 58, while Edgar and Schuyler found 608. S.'s relative error of measurement was 2.5 times smaller than that of E. and S. *I* also permits the detn. of the *reaction velocity* of such reactions in which a change of mol. nos. occurs and in which none of the reacting substance has a sufficient vapor tension to affect the total pressure; t is kept const. and p is registered at intervals. Z. Blaszkowska and M. Glowacka (Glowacka, *Dissertation*, Polytechnic School, Warsaw, 1926) have detd. $K\ 10^{-6}$ for the decompn. of *bromosuccinic acid* to be 484 in fairly good agreement with Zawidzki and Wyczakowska's detn. by the usual kinetic method. The app. will prove useful in detns. of *b. p. under high pressure*, of the *temp. coeff. of soly.* and exact b. p. of mixts. with a max. and min. b p. For *EtOH + water*, *e. g.*, identical readings on both thermometers will be obtained only for pure EtOH and the mixt. with the min. b. p. MARY JACOBSEN

A goniometer for measuring crystals in ordinary and x-ray light. K. V. VASIL'EV. *Trans. Inst. Econ. Mineral. Met.* (*Moscow*) No. **34**, 20–5(1928).—The instrument has a telescope and collimator for measurements with ordinary light, and a plate holder and slit system for x-ray work. A vertical and a horizontal circle enable orientation of the specimen to be made. R. L. HERSHEY

Registering photodensitometer. E. A. HARRINGTON. *J. Optical Soc. Am.* **16**, 211–22(1928).—A direct-reading, self-recording densitometer with single thermocouple and low-resistance D'Arsonval galvanometer, which can be used for measuring the relative opacities of photographic images of line spectra and powder photographs, is described. Quick action and small lag result from the small heat capacity of the thermocouple and special arrangement of the galvanometer. Applications to x-ray work and ordinary spectroscopy are discussed. B. C. A.

Apparatus for the determination of gas densities. M. NIKIEL. *Metan* **9**, 203–10 (1925).—The d. of a gas is compared with that of air by a detn. of the time taken for a liquid to flow out of a vessel attached to a gas supply, and then opened to the air. The app. is described and figured. B. C. A.

Thermosiphon heaters for high temperatures. HCH. ROSER. *Arch. Wärmewirt.* **9**, 285–90(1928).—The theory of the type of heater in which a liquid under pressure is used to convey heat by natural circulation is discussed. If water is used as the fluid, the limiting temp. is about 200–250°; above this point the space left in the expansion chamber is so small that a slight overheating may lead to bursting. This may be overcome by filling the expansion chamber with gas under pressure. Aniline or Hg might be used instead of water, but the cost would be greater and the lines would be larger; except for high temps. they would not be economical. Installations of this type of heater for drying and baking enamel are described and illustrated. E. W. T.

An improved Orsat apparatus for the analysis of flue gases. KARL MÜNZER. *Chem. Fabr.* **1928**, 518–20.—The "Mono" app., very similar to the Hays portable app., is described. J. H. MOORE

A small flue gas tester. A. GROSZ. *Feuerungstech.* **16**, 163–4(1928).—The CO_2 app. described contains no liquid and one cock. After the sample has flowed

through the app., a turn of the cock puts it in contact with lime. After turning over several times to mix the lime and gas, the reduction in pressure is read off on a diaphragm by making an elec. contact through a micrometer screw. The app. is 9 × 9 × 5 cm.
ERNEST W. THIELE

Pump for handling molten salts. HEINRICH OETTINGER. *Chem. Fabr.* **1928,** 516–8.—A centrifugal pump similar to pumps that have long been used in America for filling drums with fused NaOH. J. H. MOORE

Dependable heat transfer, especially in autoclaves. ALBERT SANDER. Instituto Ronzoni, Mailand. *Chem. Fabr.* **1928,** 515–6.—Heating of 2 2000-l. autoclaves under 40–50 atm. pressure and 1 larger autoclave under 12–14 atms. to 200° was satisfactorily accomplished by a combination of H_2O and oil heating. H_2O at about 200 atm. pressure was circulated through a heat exchanger where mineral oil of 270° flash was heated to 220–5°, giving the autoclaves an internal temp. of 190–200°, and requiring 20–30 kg. of coke per hr. to heat the H_2O. J. H. MOORE

An automatic time switch for prolonged heating, etc. ALEX. GUTHRIE. *J. Soc. Chem. Ind.* **47,** 202T(1928).—A household gas tap is well oiled to work freely and is screwed on to a piece of brass tubing 25 × 1.3 cm. Holes 1.7 cm. apart are drilled in the gas tap and in the winder of an alarm clock. The tap and winder are bolted face to face, their axial plane perpendicular to the place of the winder and tap. The alarm is wound up not more than 1 or 2 turns more than is required just to turn off the gas. The tube is clamped horizontally and rubber tubing is attached to each end. The alarm is set and the gas tap turned on. When the time expires the winder will rotate and turn off the gas. The device has also been used to switch off elec. current.
S. L. B. ETHERTON

Selenium cell. R. E. MARTIN. *J. Optical Soc. Am.* **16,** 279–81(1928).—A cell in which the Se is in the form of a cylinder, and a method for making the latter by pouring viscous Se are described. B. C. A.

Ultra-pressures of 25,000 kg. per square centimeter and their scientific applications. JAMES BASSET. *Chimie et industrie* **Special No.,** 148–51(April, 1928); cf. *C. A.* **21,** 3492; **22,** 516.—A description of the app. devised by B. for carrying out phys. or chem. expts. at pressures of 25,000–30,000 kg. per sq. cm., with an outline of some of its possible scientific applications. A. PAPINEAU-COUTURE

The best material for water pipes in buildings. A. BÖRNER. *Apparatebau* **40,** 196–8(1928).—In the long run Cu is cheaper and less troublesome than Fe. J. H. M.

Standard Catalogue of Scientific Apparatus, 1928. Vol. I. Chemistry. London: Baird & Tatlock (London), Ltd. 1141 pp.

Rotary sectional drum filter. DORR CO. Brit. 284,101, March 7, 1927. Structural features.

Rotary suction filter of the sector type. J. B. VERNAY. Brit. 283,876, Jan. 18, 1927.

•**Filter for water, petroleum or other liquids.** CHARLES G. HAWLEY (to Centrifix Corp.). U. S. 1,684,025, Sept. 11. Structural features.

Device for separating impurities from steam. CHARLES G. HAWLEY (to Centrifix Corp.). U. S. 1,684,024, Sept. 11.

•**Apparatus for separating or classifying coal or other materials.** WILLIAM A. RIDDELL (to Frederick Iron & Steel Co.). U. S. 1,683,918, Sept. 11.

Electron tube. FA. JOH. KREMENEZKY and KARL SCHOENBAUER. Austrian 108,526 Dec. 15, 1926. The tube includes a grid between the anode and the cathode, and a reflector on the other side of the anode.

Ebullioscope. LUDWIG FARBER. Austrian 108,558. Aug. 15, 1927. In an ebullioscope for alc. liquids, the tube connecting the heater with the condenser is bent, so that the upward flow of vapor is not impeded by the downward flow of the condensed liquid.

Combined pressure gage and thermometer for use on boilers, etc. ORVILLE W. THOMPSON (to Jas. P. Marsh & Co.). U. S. 1,683,743, Sept. 11. Structural features.

Hydrometer and enclosing chamber for testing automobile radiator liquids, etc. GEORGE A. SMITH. U. S. 1,683,735, Sept. 11. Structural features.

Refractometer. H. VOELLMY. Brit. 283,859, Jan. 17, 1927. Structural features.

Heat exchanger for gases. MASCHINENFABRIK ING. HANS SIMMON. Austrian 108,740 Sept. 15, 1927. A heat exchanger for gases is constructed as a centrifugal fan and comprises a chamber traversed by a rotary shaft on which a disk is mounted

so as to divide the chamber into two parts. Metal plates, water-filled tubes, etc., are attached to the disk.

Apparatus for cooling jets of air, anesthetic gases, etc. S. BRAUNSTEIN and S. MEERSON. Brit. 283,583, Jan. 15, 1927. Vapor from liquid air may be used as a cooling medium.

Apparatus for separating impurities from air, gas, steam, etc. CHARLES G. HAWLEY (to Centrifix Corp.). U. S. 1,684,022, Sept. 11. Structural features.

Separator and jet compressor for air and similar mixtures. WALTER MILATZ. Ger. 464,008, July 26, 1928.

Apparatus (with inclined rotary tubes heated by furnace gases) for evaporating liquids. CHEMISCHE WERKE VORM. H & E. ALBERT. Brit. 283,495, Jan. 11, 1927.

Distributing liquid currents in suspension vats. AKTIESELSKAPET KRYSTAL. Norw. 44,094, June 7, 1927. Mech. features.

Apparatus for spray desiccation of liquids. J. A. REAVELL. Brit. 284,049, Nov. 15, 1926

Device for lifting and delivering liquids in measured quantities. FRANZ GOUVION. Austrian 108,491 Aug 15, 1927. In a device of the kind in which liquid is pumped into one of two measuring vessels, the air from which passes into the other measuring vessel and displaces the liquid therefrom, the overflow pipes of the vessels are arranged to return liquid to the suction side of the pump and to serve also as the passage for the air

Apparatus and procedure for irradiating liquids by ultra-violet rays. H. SCHOLL. Brit 283,472, Jan. 7, 1927. Air may be removed from the liquid treated, *e. g.*, by use of CO_2.

Apparatus for testing the weathering properties of steel plates or other materials by exposure to water sprays and ultra violet rays, etc. C. W. JAMESON. Brit. 283,539, Feb 13, 1927.

Acetylene generator. KARL BRUNBAUER and EDMUND PRUSENOVSKY. Austrian [illegible], Sept. 15, 1927. An acetylene generator for inflating a life belt is described.

Apparatus for catalytic reactions. PETROLE SYNTHETIQUE SOC. ANON. Brit. [illegible], Jan 18, 1927. Gases or the like are subjected to heat and contact with a catalyst in a narrow space which may be of annular form "of the order of a few mm. in thickness" and are subsequently cooled in a similar app. Various structural details are [illegible].

Apparatus for catalytic reactions. A. O. JAEGER (to Selden Co.). Brit. 283,887, [illegible] 19, 1927. At least one converter of a catalytic converter system is provided with cooling means sufficient to enable it to operate at rates in excess of normal conv. output, followed by at least one converter of much less effective cooling capacity, with or without coolers or heat exchangers between the 2 stages. Numerous details of construction are described and the app. is suitable for various reactions including reduction, dehydrogenation, hydrogenation, halogenation, oxidation and condensation, as in the production of SO_3, MeOH, oxides of N or NH_3 or the treatment of water gas. Also U. S. 1,685,672, Sept. 25.

Furnace. NAAMLOOZE VENNOOTSCHAP STIKSTOFBINDINGSINDUSTRIE "NEDERLAND." Ger. 463,718 July 19, 1928. Furnace for high-temp. normal pressure reactions with walls with outer layers of refractory materials, an inner layer of metal and an intermediate layer of liquid or gaseous material.

Muffle furnace for annealing. BRITISH FURNACES, LTD. AND E. W. SMITH (Surface Combustion Co.). Brit. 283,767, March 22, 1927.

Use of natural olivine rock for furnaces or other apparatus exposed to high temperatures or to chemical action. V. M. GOLDSCHMIDT and R. KNUDSEN. Brit. 283,791, June 22, 1927. Solid pieces may be used or smaller pieces may be agglomerated with a binder such as colloidal Mg silicate, MgO, $Mg(OH)_2$, talc, lime, clay or bituminous material.

Tunnel kiln suitable for calcining, firing, etc. HARRY M. ROBERTSON. U. S. 1,683,807, Sept. 11. Structural features.

Rotary kiln for manufacture of cement by the wet method, distilling carbonaceous materials, drying coal, limestone, clay, etc. E. ALLEN & CO., LTD. AND W. J. COLES. Brit. 283,669, Oct. 29, 1926. Structural features.

Heat-control device for ovens. ALVIN G. SHERMAN, GEORGE H. RAMIG, GEORGE SMITH and CYRIEL A. ROOSE. U. S. 1,684,205, Sept. 11.

Apparatus (with superposed sections containing rotary trays) for drying cereals, ammonium sulfate crystals, etc., or for carbonizing coal. R. V. FARNHAM. Brit.

283,717, Dec. 18, 1926. Heating gases may be passed into the uppermost section and exhausted from the lowermost.

Acid-proof linings for vessels in which materials are heated. I. G. FARBENIND. A.-G. Brit. 283,964, Jan. 22, 1927. Slabs of cast Si are used for making linings.

Steam feed regulator for apparatus for production of hydrogen from steam and iron. COMPAGNIE DE PRODUITS CHIMIQUES ET ÉLECTROMÉTALLURGIQUES ALAIS, FORGES ET CAMARGUE. Ger. 463,947, July 19, 1928.

Valve for carbon dioxide cylinders. LUX BRANDSLUKNING A. S. Norw. 44,913, Feb. 27, 1928.

Apparatus and system for testing materials under vibratory stresses. LOSENHAUSENWERK DÜSSELDORFER MASCHINENBAU A.-G. Brit. 283,787, June 13, 1927.

Thermionic active cathode material. STANDARD ELECTRIC A. S. Norw. 44,658, Nov. 28, 1927. Equimol. quantities of Ba or Sr carbonate and metallic Ni are heated to about 1200° in the presence of air or O_2 by which are formed nickelites of Ba or Sr. The product is crushed and pulverized and mixed with Pt powder in amts. varying from 50 to 99%. The mixt. is molded by pressure to a rod of the desired dimensions which is placed in a vacuum furnace and heated to about 1600° by which the nickelites are decomposed and the earth alk. oxides are obtained in uniform and very fine distribution in the Pt-Ni rod which can now be worked to wire.

Thermostat formed of connected metal plates of different coefficients of expansion. PERRY S. MARTIN. U. S. 1,683,908, Sept. 11.

Thermostatic device (with a tilting mercury switch) for furnace chambers, etc. N. H. FREEMAN. Brit. 284,008, Oct. 19, 1926. Structural features.

Ancient and modern mummification. HERMANN STADLINGER. *Pharm. Zentralhalle* **69**, 483–5(1928).—Beginning with the earliest known procedures of the Egyptians down to the most recent patented and other reported processes, the author describes the various more or less successful methods for perpetuating animal remains in both form and substance. W. O. E.

Nomography. II. O. LIESCHE. *Chem. Fabr.* **1928**, 228–30, 241–3; cf. *C. A.* **22**, 3858.—The construction of charts for the reading of analytical results of the type corresponding with the relation $y = f(x)$ is developed. In the detn. of $BaSO_4$ by sedimentation the original curve is parabolic. If the relation is linear as in the iodometric detn. of Sb, sulfites, etc., the chart takes the form of 2 scales at an angle. A more complicated linear relationship is found in the conversion of wt.-% into at.-% in alloys, *e. g.*, of Mg-Cu. The direct construction method cannot be used directly for non-linear relationships, but by breaking up the equation it may be partly applied. The method may be equally applied to empirical data as in the distn. of a mixt. of water and C_6H_6. B. C. A.

Nomography. III. Logarithmic and exponential functions. O. LIESCHE. *Chem. Fabr.* **1928**, 359–61, 392–4; cf. preceding abstract.—The use of logarithmic scales facilitates the graphical soln. of numerous problems. Various examples are given of the combination of a logarithmic scale and an equally divided scale or of two logarithmic scales arranged either parallel or "projectively" at an angle for the graphical detn. of the breaking down of meso-Th, the variation of a reaction velocity with the temp., the iodometric detn of Sb, etc. B. C. A.

Physical methods in chemical laboratories. I. Introduction. F. PANETH. *Z. angew. Chem.* **41**, 507–8(1928).—An introductory discussion. **II. Vacuum technic.** K. PETERS. *Ibid* 509–15.—Modern methods of evacuation, measurement of pressure and investigation of in-leaking are reviewed and the scope of the application of vacuum methods to analytical, photochemical, preparative and other problems is briefly outlined. A number of diagrams and references are given. **III. Production of intense magnetic and electric fields.** H. GEHLEN. *Ibid* 714–6.—Modern methods for the production of intense magnetic and elec. fields are briefly described. **IV. Significance of spectroscopy in chemical investigations. I.** E. RABINOWITSCH. *Ibid* 555–61.—Energy-levels and term-systems are briefly explained, and the methods whereby heats of ionization and dissocn. are deduced from spectroscopic evidence are indicated. B. C. A.

The rare elements. FREEMAN P. STROUP. *Am. J. Pharm.* **100**, 499–509(1928).—A popular lecture. W. G. GAESSLER

Available energy. ROBERT A. MILLIKAN. Norman Bridge Lab. of Physics. *Ind. Eng. Chem.* **20**, 1117–21(1928) *Science* **68**, 279–84. E. H.

Molecular weights of saturated vapors by the effusion method. HENRY EYRING. Univ. of Wis. *J. Am. Chem. Soc.* **50**, 2398–2401(1928).—The success of the effusion method for the detn. of mol. wts depends upon accurate time and pressure measurements, and upon the selection of a size of orifice which reduces viscosity effects to a min. Under these favorable circumstances, an accuracy of 1% is attainable. An all-glass app. is described. Mol. wt. detns. of the vapors of Me, Et and Pr alcs., C_6H_6, CCl_4 H_2O and $CHCl_3$ gave the values: 32–32.8, 46.5–45.4, 56.2–60, 77.6–77.3, 152, 184 18.54 and 116.5, resp. The data for satd. H_2O vapor and the org. vapors at room temp. indicate that there is no assocn. in the vapor phase. J. H. PERRY

Molecular and atomic volumes. XVII. The space and magnetochemistry of the solid cyanides. WILHELM BILTZ, W. ESCHWEILER AND A. BODENSIEK. *Z. anorg. allgem. Chem.* **170**, 161–83(1928); cf. *C. A.* **22**, 360.—The ds. of numerous complex solid cyanides were detd. The methods of prepn. of these cyanides are given. The solubilities for series of the salts is also given. Some salts not previously described are reported, as $ZnNi(CN)_4$, which was pptd. from a $K_2Ni(CN)_4$ soln. by $ZnSO_4$. A greenish yellow amorphous $NiAu_2(CN)_4$ was prepd. by treating a $KAu(CN)_2$ soln. with $Ni(NO_3)_2$. This gave a white, finely cryst. ppt., which contained too little Au. This gave after 1/2 hr's. digestion on the water bath with 0.5% H_2SO_4 and 4 days' drying *in vacuo* at 150° a pure yellow anhydride, which gave upon hydration a white hydrate. $NiW(CN)_8$, a yellow-green ppt., gave after 3 days' drying at 150° *in vacuo* a grayish brown amorphous ppt. For analysis, the cyanides were decomposed with concd. H_2SO_4 or pyrosulfate, and in rare cases, with aqua regia. The d. measurements are accurate to 0.01%, but on account of the various sources of error introduced by the amorphous nature of the prepn., pseudo-vols. due to hydration, occlusion, etc., the accuracy of the results may be lessened to a certain extent. The observed values are in good agreement (< 1%), on the whole, with those values detd. from x-ray d. measurements. There are no direct measurements upon the solid cyanides for the detn. of the vol. relations. However, it is possible to det. the null point of 20–24 cc. by a study of isosters of org. substances, and $Ca(CN)_2$. Most of the simple cyanides give values of 20–24 cc. for the CN vol. The bivalent metals show a greater spacing, 20–30 cc., except that $Ni(CN)_2$ has a vol. of 20 cc. For the double K cyanides, the contraction is greater,

the higher the coördination number. The same is observed for the Werner ammonium complexes and for the luteo-complexes, but not for the weaker ammonium complexes. The relation between the stability and the spatial requirements of the cyanides cannot be ascertained. The position of the central atom in the periodic system is also essential. The dilatation, in each group, increases with the at. wt., as is also the case with the solv. of the salts. If H is introduced instead of K, no fundamental changes are observed. For the heavy-metal cyanides, the same values are, in part, obtained as for the K salts, and the others are more widely spaced. The polymerization of the heavy-metal double cyanides is discussed. According to the theory of Abegg and Bodländer the stability of the complex is dependent upon the electro-affinity of the central atoms, that is, the more noble metal forms the central atom of the complex, and the more common element the individual ion. If both metals are equally noble, the ordinary schematic formulas, as $Ni_2[Fe(CN)_6]$ and $FeNi[Ni(CN)_6]$ are suggested. In order better to understand the behavior of the above complexes, the Ni may be pptd. out by means of dimethylglyoxime. It is of interest to note that in most of these cases, the normal CN value appears, which makes an explanation even more difficult. The CN vols. for a series of hydrates and cyano salts whose ds. are listed in the literature are given, as well as the good agreement of those values with those of the cyano-cobalt ammines which had been measured by Hassel and Salvessen by x-ray methods. Fulminic acid (O_2 value 1.6–3.9 cc.) and thiocyanates ($S < 15$ cc.) are briefly mentioned. According to Sidgwick's rule, those complexes are favored which have an effective at. number similar to the atomic no. of the next following rare gas. Central atoms, in these cases, which were formerly paramagnetic according to Welo and Baudisch are diamagnetic. The above behavior is fulfilled by the cyanides. The variation of the effective at. no. of those groups showing similarity to the rare gases corresponds closely to the Bohr magneton no. Further, it is also shown, by Sidgwick, that those complexes are the most stable in which the coördination no. attains the expected value, that is, which gives the rare-gas configuration. Isomeric diammino cobalt chloride shows a similar magnetic behavior. Luteo cobalt oxalate is diamagnetic although it varies in space chemistry from the luteo chloride. It is suggested also that the hexammine of Fe is not remarkably stable, and is also paramagnetic, whereas it should have about the same behavior as the luteo salts. In the dipyridyl complex, a diamagnetic Fe salt is known. Entirely in disagreement with Sidgwick's rule is the diamagnetism of $K_2[Ni(CN)_6]$, which W. Klemm detd. both on the hydrate and anhydride on prepns. of C. Fendius. L. L. Q.

Molecular and atomic volume. XX. Space requirements of hydrogen in metallic hydrides. WILHELM BILTZ. Tech. Hochschule, Hanover. *Z. anorg. allgem. Chem.* **174**, 42–6(1928); cf. *C. A.* **22**, 3324; and Proskurnin and Kazarnovskii, *C. A.* **22**, 3851.—In alk., alk. earth and rare earth hydrides the relation of calcd. to observed mol is 2.02 ± 0.03. In hydride formation from these elements there is therefore a contraction from zero-point, vol. to about $^1/_2$, and the H vol. in the hydrides is on the av. 5.7. With V, Cr and Pd, however, the contraction of the elements with hydride formation is much less, the ratio of the calcd. to the observed values being 1.59 for V hydride, 1.33 for Cr hydride and 1.55 for Pd hydride. These are really not compds. but solns. of H in the metal. With Zr and Ti, however, the hydrides behave like the alkali hydrides in respect to vol. contraction, the ratio of calcd. to observed mol. vol. being 2.2 and 2.3. H. STOERTZ

Determination of the coefficients in chemical reactions by positive and negative valences. IGNACIO PUIG. *Atti congresso naz. chim. pura applicata* **3**, 1259–82 (1927).—Rules for the sign of the valences. H functions always +1 when united to metalloids and −1 when united to metals. The first case is more frequent, the second occurring only in the hydrides. Metalloids show greater variety in sign of valence. When metalloids are united with H or with metals they are negative and when united to other metalloids the more negative unites by its negative valences. Thus O, next to F the most neg. element, unites with all other metalloids by its neg. valence. Metalloids forming part of acids possess the same valency as in the corresponding hydrides. Metals almost always function positive to metalloids in metal/metal unions, the more electronegative functions with neg. valence. [illegible] the number of valences are: when an atom of an element forming part of a mol. is linked to similar atoms [illegible] one or more valences these valences are negligible; for metalloids, the fundamental valence in oxidized compds. is the same as in anhydrides; in acids the metalloid has the same valence as in the corresponding anhydride; in salts the metalloids have the same valence as in the acids or anhydrides which yield these salts. Metals always have the ordinary valency usually assigned. Examples are given of practical process

for detg. the valence and of the resolutions of reactions capable of multiple solns. Examples are given of the fundamental rule for the calcns. of the coeffs. *viz.*, that in every reaction the no. of oxidized valences equals the no. reduced. There is a bibliography of 16 references, of which over half are in Spanish. S. L. B. ETHERTON

The modifications of carbon. W. A. ROTH. *Z. angew. Chem.* **41,** 273–8(1928).—A review. E. H.

Evidence of the anisotropy of the carbon atom. KATHLEEN LONSDALE. *Phil. Mag.* [7], **6,** 433–45(1928).—The possible symmetry of the C atom is investigated in the light of x-ray results on crystals of C_2Cl_6 and isomorphous compds. A model is obtained having two A and two B valencies, geometrically different and a comparison is made with the Main Smith-Stoner atom. Work in other fields is also quoted in favor of a non-tetrahedral C atom. A crit. account is given of the controversy concerning pentaerythritol and other symmetrically substituted derivatives of CH_4, and it is shown that no case of a pyramidal C atom has yet been satisfactorily proved. It is found that the model now suggested will explain the symmetries, as detd. by means of x-rays, of other simple C compds., in some cases throwing light on anomalies revealed by such detns. GEORGE GLOCKLER

The structure of iron nitride, Fe_4N. R. BRILL, I. G. Farbenind. A.-G., Ludwigshafen. *Naturwissenschaften* **16,** 593–4(1928).—Hägg has claimed that N is taken up by Fe as a solid soln. Several years ago B. found on strongly overexposed x-ray diagrams of a nitride of compn. Fe_4N 4 very weak lines not originating from the face-centered Fe atom lattice, but indicating a regular distribution of N. The positions corresponding to the diagram are Fe: 0, 0, 0; $^1/_2$, 0, $^1/_2$; $^1/_2$, $^1/_2$, 0; 0, $^1/_2$, $^1/_2$ and N: $^1/_2$, $^1/_2$, $^1/_2$ with a cube dimension of 3.80 A. U. This means a chem. compd Fe_4N. B. J. C. VAN DER HOEVEN

The crystal structure of the alums. L. VEGARD AND E. ESP. *Ann. Physik* **85,** 1152–64(1928).—The structures of $NH_4Al(SO_4)_2.12H_2O$, $KAl(SO_4)_2.12H_2O$, $NH_4Fe(SO_4)_2.12H_2O$ and $KCr(SO_4)_2.12H_2O$ were studied by the Debye-Scherrer method. They are cubic with the following cube edges, resp.: 12.11 A. U., 12.08 A. U., 12.165 A. U., 12.03 A. U. The space group is T_h^6. There are 4 mols to the unit cell. The univalent and tervalent atoms lie on a NaCl type lattice in each eighth of the unit cell; a SO_4 group lies on the trigonal axis, the S atom and one of the O atoms lying on the axis and the other O atoms lying in a plane perpendicular to the axis. The O atoms of the H_2O mols. are arranged in cubic closest packing along the trigonal axis and next to the univalent metal atom. The basal plane of the sulfate group tetrahedron lies toward the water and not toward the tervalent metal atom. There are 11 parameters, which have not been quantitatively detd. R. L. HERSHEY

The structure of beryllium oxalate. L. HAVESTADT. *Z. anorg. allgem. Chem.* **171,** 351–4(1928).—$Be(COO)_2.3H_2O$ is orthorhombic. The unit cell contains 4 mols and has the dimensions, a = 6.37 A. U., b = 7.53 A. U., c = 12.45 A. U. The space group is V_h^{16}. The method of the rotating crystal was used in the analysis. R. L. HERSHEY

The crystal structure of tetraethylammonium iodide. ISAMU NITTA. *Proc. Imp. Acad. Tokyo* **4,** 292–5(1928).—Laue and spectrometric measurements show that $N(C_2H_5)_4I$ is tetragonal body-centered with 2 mols. to the unit cell. The cell dimensions are: a = 8.85 A. U. and c = 6.93 A. U., d is calcd. to be 1.56. The space group is probably S''. The intensity data are not sufficient for the exact placing of the atoms in the cell. R. L. HERSHEY

The crystal structure of tetraethylammonium iodide. R. W. G. WYCKOFF. Rockefeller Inst. for Med. Res. *Z. Krist.* **67,** 550–4(1928). (In English.)—Two mols. of $N(C_2H_5)_4I$ are contained in a tetragonal cell with the dimensions a = 8.87 and c = 6.95 A. U. The I atoms are body-centered. The N atoms, as centers of the $N(C_2H_5)_4$ groups are either body-centered or else similar to those in $N(CH_3)_4I$. (Cf. *C. A.* **22,** 2861.) L. S. RAMSDELL

Crystallographic investigation of some rare-earth nitrates. E. E. FLINT. *Trans. Inst. Econ. Mineral Met.* (Moscow) **1928,** No. 34, 59–72.—Goniometric and optical measurements are reported on the salts: $3Mg(NO_3)_2.2Ce(NO_3)_3.24H_2O$; $3Mg(NO_3)_2.2Nd(NO_3)_3.24H_2O$; $3Mg(NO_3)_2.2Pr(NO_3)_3.24H_2O$; $3Mg(NO_3)_2.2La(NO_3)_3.24H_2O$. Reference must be made to the original for numerical data. F. emphasizes the necessity of indicating the degree of precision of goniometric measurements. These crystals cannot be distinguished goniometrically; hence F. has taken especial care in the detn. of their n's. R. L. HERSHEY

The crystal structure of mercuric cyanide. R. FRICKE AND L. HAVESTADT. *Z.*

anorg. allgem. Chem. **171,** 344–50(1928).—$Hg(CN)_2$ is tetragonal. The unit cell dimensions are: $a = b = 9.74$ A. U., $c = 8.94$ A. U. It contains 8 mols. and is body-centered. The most probable space group is V_D^{12}. The x-ray method of the rotating crystal was used. R. L. HERSHEY

The crystal structure of titanium monoxide. H. BRÄKKEN. *Z. Krist.* **67,** 547–9 (1928).—TiO has a NaCl type of structure, with $a = 4.235$ A. U. The calcd. d. is 5.536. The data seem to indicate that the compd. is not ionized. L. S. RAMSDELL

The crystallography and optical properties of β-lactose. EDGAR T. WHERRY. *J. Wash. Acad. Sci.* **18,** 302–4(1928).—Crystals of β-lactose are transparent and colorless and belong to the holo-axial polar class of the monoclinic system. The axial ratio is $a:b:c = 0.817:1:0.377$; the acute monoclinic angle, μ, is 88°15′. The n's are: $\alpha = 1.542$, $\beta = 1.572$, $\gamma = 1.585$. A procedure for distinguishing by optical means, between α-lactose, β-lactose and sucrose is given. R. L. HERSHEY

Uniformly colored crystals, which form from melts sufficiently supercooled. G. TAMMANN AND F. LAASS. *Z. anorg. allgem. Chem.* **172,** 65–83(1928).—Homogeneously colored crystals were obtained by strong supercooling; they are not mixed crystals; the pigments are contained in minute particles distributed in a mass which is still seen to be homogeneous with a 500 times magnifying power. The following shows that even this mass is not a mol. mixt. (1) Above the eutectic temp. a sepn. occurs with the formation of the eutectic soln. (2) In the crystals which appear homogeneously colored, the pigments are not protected against the attack of non-colored satd. solns. (3) Colorless crystals ppt. out of less viscous (alc.) colored solns. Conclusion: The homogeneously colored crystals contain the dye as mol. conglomerates, not as mols. The high viscosity of the melting and the crystn. velocity cause an abnormal formation of the crystals. It is impossible to make any distinction between the crystals primarily sepd. and the eutectic. The dye does not envelop the crystals first sepd. in the eutectic, but disperses in smaller and smaller particles in the crystals, which cause a homogeneous coloration; the dichroism is to be referred to a regular repartition of the dye particles O. Lehman has mentioned colored crystals (*Wied. Ann* **51,** 47(1894)), which were obtained from alc. solns. Meconinic acid contains Me violet and probably the other dyes too, as mols, but phthalic acid does not, at least within certain limits. With increasing crystn. velocities, differences in the compn. of the melt decrease and also the differences in the crystals sepd. therefrom. With large crystn. velocities, the differences disappear completely. A. L. HENNE

Change of color of crystals at low temperatures. I. OBREIMOV AND W. J. DE HAAS. *Proc. Acad. Sci. Amsterdam* **31,** 353–6(1928).—See *C. A.* **22,** 1908. E. H.

The influence of urea on the crystal habit of sodium chloride. F. GILLE AND K. SPANGENBERG. *Z. Krist.* **65,** 204–50(1927).—The addn. of urea to NaCl solns. causes a marked fall in cond., which is due to formation of double salts as well as to increased viscosity. The double salt $NaCl.CO(NH_2)_2.H_2O$ occurs in platy orthorhombic crystals, optically positive, with optic angle = 37°, and with the 3 indices α, β, γ = 1.479, 1.485 and 1.543, resp The relative growth velocity in pure H_2O for NaCl is $v_{100}:v_{111}:v_{110} = 1:3.2:6.8$ and for soln. with 33.5 g. urea per 100 cc. 1:0.25:1.9. At a concn. of 5 g. urea per 100 cc. soln. the form (111) begins to appear with (100) and at 8.5 g. the form (111) without (100) is the end form. L. S. RAMSDELL

Solid solutions of chromium and nickel and of iron and nickel. F. C. BLAKE, JAMES LORD AND A. E. FOCKE. *Phys. Rev.* **29,** 206–7(1927).—Cr goes into the Ni lattice up to 63% Cr by wt., the max. distortion being 2.8%. From 63 to 100% Cr the Ni is in the face-centered Cr lattice, but this lattice being metastable at ordinary temps. most of the Cr seps out as body-centered Cr. In Fe and Ni, Fe distorts the Ni lattice up to 74% Fe by wt. after which the Ni is in the face-centered Fe lattice up to 100% Fe; but face-centered iron is stable only at high temps.; so most of the Fe seps. out at room temp. In both cases miscibility is complete, but there is overlapping between the regions of distorted face-centered Ni-Cr (or Ni-Fe) and body-centered Ni-Cr (or Ni-Fe). On account of the small difference in lattice between isomorphs of Cr, Ni and Fe, a higher precision in the x-ray method is necessary to det. whether the phase which separates out contains both methods in the body-centered state.
R. L. HERSHEY

Transformation in the lattice structure of metallic solid solutions. G. BORELIUS, C. H. JOHANSSON AND J. O. LINDE. Physik. Inst. techn. Hochschule, Stockholm. *Ann. Physik* **86,** 291–318(1928); cf. *C. A.* **20,** 1154; **21,** 2204.—Further and more refined measurements of the resistance of the solid soln. series Cu-Au and Cu-Pd have been made in an attempt to establish, definitely, the existence of a transition from a

statistical to an ordered distribution of the atoms on the lattice. Complete state and resistance diagrams are given for these 2 alloy series. The resistance-compn. diagrams for the Cu-Au series at 450° and for the Cu-Pd series at 600° as well as for the same series quenched from the higher temps., show no deviations from the smooth curve which indicates that under these conditions the distribution is statistical. When the alloys are slowly annealed, however, sharp diminutions in the resistance occur in the range of compns. represented by the at. relations 3 Cu : Au; Cu : Au; 3 Cu : Pd and Cu : Pd, which indicate that a transition has taken place between the statistical and ordered distribution. A marked temp.-resistance hysteresis was observed which reached its max. at the compns. represented by the above at. ratios. The transition and hysteresis phenomena have been considered on the basis of thermodynamic equil.

A. J. KING

A test of Tammann's theory of resistance limit with the system: gold-copper. A new point of view. M. LEBLANC, K. RICHTER AND E. SCHIEBOLD. *Ann. Physik* **86**, No. 7, 929–1005(1928); cf. *C. A.* **19**, 2891.—The accuracy of the $N/8$ mol. law of Tammann was tested by means of Au-Cu alloys which are well adapted for x-ray study and for the detn. of limits in resistance to soly. The prepn. of the alloys with varying Cu content and free from impurities is described. Samples of untempered alloys and samples tempered for 29 days at 840° were extd. with HNO_3 (sp. gr. 1.4) contg. 1% N_2O_5 first for 61 days and then for an addnl. 15 days at 22°. In the tempered alloys Cu showed a high resistance to the acid up to a Cu content of $^5/_8$ mol. fraction, at which compn the alloy dissolved almost completely. The untempered alloy showed a high resistance up to 4.8/8 mol. fraction, at which point the resistance dropped rather abruptly. When further extd. with HNO_3 (sp. gr. 1.5) at 22° for 14 days the untempered alloys did not dissolve further to any appreciable extent but the Cu in the tempered alloy with a Cu content of 4.8/8 mol. fraction dissolved appreciably. The extn. was continued for 14 days at 55°. There was little further soln. of the untempered samples. With the tempered samples only the alloy with a Cu content of 4.8/8 mol. fraction dissolved appreciably. At the end of the test both the tempered and untempered samples with a Cu content of 4.8/8 mol. fraction had lost practically all their Cu while the samples with a lower Cu content had lost very little. The original alloy leaflets had disintegrated into a powd. mass in all tempered samples. With the untempered samples this was not true of the samples with a Cu content of less than 4.8/8 mol. fraction. These results do not coincide with the Tammann theory. Temp. has a noticeable effect, the HNO_3 concn. exerts a strong influence, the resistant mixed crystals with a Cu content of 4.4/8 mol. fraction and less are dissolved to depth of almost 1000 atoms, and there is remarkably little difference between tempered and untempered alloys. A comprehensive x-ray study of the Cu-Au alloys was made and space lattice data are given. The cubic lattice for $^2/_8$, $^4/_8$ and $^6/_8$ mol. fraction of Cu as predicted by the Tammann theory was not confirmed. The relation between the limit of resistance and the space lattice structure of the Cu-Au alloys is discussed. An abs. limit of resistance, independent of the temp. and the character of the solvent is not believed to exist.

J. S. REICHERT

Strains and their removal by breaking and gliding. F. RINNE. *Z. Krist.* **64**, 537–9; *Physikal. Ber.* **8**, 735(1927).—Primary and secondary strains are distinguished and the phenomena in particles, atoms, mols., crystals, glass, atmospheric and geological processes considered in light of strains and their relief.

G. L. CLARK

The x-ray diagrams of liquids as an expression of the shape and arrangement of the molecules in the liquid state. J. R. KATZ. *Z. angew. Chem.* **41**, 329–40(1928).—Since so little is known concerning the relation between the so-called "amorphous spectra" given by liquids and the shape and arrangement of the mols., K. has undertaken a study of a large series of liquids, using org. compds. because their structure has been worked out from chem. evidence, and because homologous series are available. If the mols. are assumed to be spherical, $a = b$, where $a = (1/0.814)(\lambda/2 \sin \theta/2)$ and $b = 1.33\sqrt[3]{v}$, θ being the angle between the diffracted and the original x-ray beams and v the mol. vol. The deviation from this equation thus shows the deviation of the mols. from the spherical form; d, calcd. from the Bragg formula, is $0.814\,a$. However the derivation of the formula for a contains uncertainties. If the mols. of the liquid contain several like groups, two rings are obtained, the inner ring corresponding to the av. distance between the centers of mols., the outer to the distance of nearest approach of these like groups. If the mols. are rod- or disk-shaped, a large vol. change should occur on melting a solid unless the mols. are easily deformed and perhaps arranged at random, or, if rigid, arranged parallel in groups. K. considers that mols. must possess ordered arrangement in the liquid, since crystn. can take place so quickly on cooling.

Liquids whose mols. differ widely from the spherical form show two or more diffraction rings, and therefore must have groups of regularly arranged mols. in which two or more spacings due to mol. size are regularly repeated. These groups are arranged at random. In the cryst. state, the distance between the lattice planes does not necessarily give mol dimensions, and the axes of the mols. are not necessarily parallel to the axes of the crystal. The same is true of the liquid state. Thus the problem of detn. of mol. shape and size is complicated, in general. There is need of comparing results obtained from a very large no. of related compds. As examples of studies of this type, K. gives data on liquids whose mols. contain two rings, as naphthalene, quinoline, etc., for which, from Bragg's at. diams., the thickness of the mol. should be 3.0 to 3.8 A. U., depending on the form of the benzene model assumed. The x-ray diffraction patterns of these liquids show two rings, sometimes three. The diam. of the inner ring varies with the substance, and its a value agrees well with b as calcd. from mol. vol. The outer ring has nearly the same diam. for all, giving $d = 3.6_5$ A. U. in most cases, though sometimes as low as 3.3_5 or as high as 3.8. Benzene and phenol give halos with sharp borders corresponding to $d = 3.0$ A. U.; the introduction of several side chains as $-CH_3$, and other groups as $-NO_2$, $-Cl$, raise this value to about 3.6 A. U., the inner ring as before, varying with the substance. The simplest assumption concerning the common dimension 3.6_5 A. U. is that it measures the mol. thickness. As side chains are added, this dimension increases, the agreement between a and b becomes less exact, and the outer ring becomes more intense. Upon complete hydrogenation of a double ring mol. the outer ring disappears and but little remains of the diffuse blackening: if only one ring is hydrogenated, the outer ring disappears, but the diffuse blackening remains Hydrogenation weakens the rigid disk form of these mols. and makes them more easily deformed and perhaps thicker. $\Delta^{9,11}$-Octalin, because of the double bond between the C atoms common to the two rings, should have more rigidity than $\Delta^{2,3}$-octalin and should give a halo with a more sharply defined border. This was exptly. verified No clear difference could be detected between *cis* and *trans* decalins. Complete hydrogenation of di- and trimethylbenzenes causes disappearance of the outer ring. 3,5-Dimethylcyclohexanol in the *cis* form gives a stronger halo than in the *trans* form; with the corresponding ketones, the *cis* form gives a sharply bordered halo, while that of the *trans* form is weaker and more diffuse. This is attributed to the more regular disk shape of the *cis* form. Of the large C rings, K. has studied the series of Ruzicka's cyclic ketones, C_8 to C_{11}, and C_{15}. For the lower members, a_1 and b agree well, and the outer ring does not appear. As one goes up the series, the deviation between a_1 and b becomes greater and the outer ring increases in intensity until for C_{15} it is more intense than the inner. The values of d calcd. from the outer ring range from 3.25 A. U. for C_7 to 4.53 for C_{15}. Normal aliphatic compds. give an outer ring corresponding to $d = 4.5$ A. U., $a = 5.5$, if the chain contains more than 4 C atoms. The inner ring is much weaker, because of the less frequently repeated spacing along the long dimension of the mol This, and the fact that this ring lies so near the central beam make its accurate measurement difficult, especially for the longer-chain mols. The d value for the inner ring increases a definite amt. for each C added to the chain. This increment has one value for liquid acids of even no. of C atoms, and another for those of odd no., in agreement with Trillat's work on cryst. acids. The value of d_1 must be an expression of mol length, that of d_2, the av. diam. of the cross section, for with a branched-chain isomer, d_1 is smaller, while d_2 is larger. From these values, K. concludes that the mols. must be rigid, and therefore, to account for the small vol. change on melting, must lie together in groups. No inner ring was detected with normal amines, ketones and paraffins, if present it is much weaker than with other O-contg. compds. O-contg. groups are more polar and supposedly cause a more definite arrangement of the mols., perhaps an asmocn. The value of the long spacing seems to correspond to the length of two mols in case of normal compds. (alcs., acids, aldehydes) and also with cyclic alcs., though the existence of double mols. with the tertiary alcs. is doubtful. These show an increment per CH_2 added, which is only half that found for the normal alcs. Two possibilities are suggested to explain the occurrence of two or more diffraction rings: either the mols. lie in small groups with lattice-like structure, or the interferences are due to repeated oscillations of the mols. But the intensities of these diffraction rings are of the same order of magnitude as crystal interferences. Hence if they are due to such oscillations, the mols. must at all times be touching others on all sides, *i. e.*, possess a lattice-like arrangement. The shape and size of the mols. necessarily affect this lattice like array, and a study of the x-ray interferences can thus give an insight into mol. shape and size. While the results may seem to contradict the evidence adduced from some chem. reactions, it must be remembered that the x-rays here show the form of

the large percentage of mols., and a deformity of a very small fraction would not be detected. G. R. Yohe

X-ray investigation of lauric acid. Rudolf Brill and Kurt H. Meyer. *Z. Krist* **67**, 570–82(1928).—Lauric acid was obtained in platy crystals, optically positive, with weak double refraction, and an index of about 1.48. The x-ray data indicate a monoclinic cell, with *a* 9.76, *b* 4.98, *c* 36.9, 48, 68, containing 4 mols. L. S. R.

Influence of x-rays on the crystallization of bismuth. A. Rostagni. Univ. Torino. *Atti accad. Lincei* [6], **7**, 649–53(1928).—Since the influence of x-rays and γ-rays on certain properties of Bi and allied metals reported by Adinolfi (cf. *C. A*. **19,** 1224, 3216; *Boll. soc. nat.* **38,** 114 (1926)) and by Campa (*C. A*. **20,** 3262; **21,** 3004) may have depended upon accidental factors, expts. on the influence of x-rays on the thermoelec. power and on the sp. heat of Bi were carried out. The app. and technic, which are described in detail, allowed measurements of these properties in identical samples of Bi which had been fused and then crystd. with and without irradiation by x-rays during the crystn. There was no difference either between the thermoelec. power or the sp. heat of the samples which had been irradiated and those which had not been. As judged by 2 important properties of metals, x-rays do not therefore alter the structure of Bi during its crystn. The *sp. heat* was 0.03023–0.03030 (cf. Schimpff, *C. A*. **4,** 1129). C. C. Davis

Some physical properties of gas-freed sulfur. C. Coleridge Farr and D. B. Macleod. *Proc. Roy. Soc.* (London) **A118,** 534–41(1928).—S purified in the ordinary way, by simple distn., may contain SO_2, traces of H_2SO_4, and H_2S. Its viscosity varies and depends on its heat history. This and other phys. properties are not const. because of the retardation of inner equil. between the S modifications present. S with a const. and definite viscosity would be definite in its other phys. properties. Com. S on distn. shows a considerable residue of carbonaceous matter. The S used was prepd. from S crystd. from CS_2 and from com. flowers of S. It was then distd. in an all-glass app. in CO_2 followed by distn. *in vacuo*. The viscosity was detd. at the temp. of greatest variation, 163–169° and reproducible values of viscosity were obtained with sulfurs of various heat treatments. "Mother of Pearl" S, S_{III}, from the purified S, contrary to the usual behavior, seps. with great ease and is very stable. Its natural f. p. is 103.8–103.9°, the ideal m. p. *i. e.*, of S_{III} in contact with S, melts at about 107°. The natural f. p. of monoclinic S was 114.6°. Efforts to obtain rhombic S failed. The pure S can be supercooled to 80° and at this temp. it is 4 times as viscous as at 155°. S. L. B. E.

The validity of gas equations. V. W. Herz. *Z. Elektrochem.* **34,** 360–2(1928); cf. *C. A.* **22,** 3326.—Exptl. data for hexane, octane, diisobutyl, cyclohexane, C_6H_6, Et_2O, Me, Et and Pr formates, CCl_4, MeOH, EtOH, PrOH, $SnCl_4$, NH_3, SO_2, Cl_2 A, N_2 and O_2 show that the vol. of 1 g. calcd. by the perfect gas law is about 3.75 times larger than that found by expt. At $^9/_{10}$ the crit. temp. (abs.) (T_c) this ratio is 1.45 and at $^1/_3$ T_c (abs.) the ratio is equal to 1. J. H. Perry

Friction coefficient for gas flow through small glass tubes. Marshall Elliott. Univ. of Texas. *Ind. Eng. Chem.* **20,** 923–4(1928).—The most generally suitable type of flowmeter is a capillary glass tube connected to T's at both ends. With proper functional relations or with exact calibration the rate of gas flow through such a tube can be detd. from the observed pressure drop between the two T's. From the Fannin equation $\Delta h = 2\,fLu^2/gd$, where h = loss of head between 2 ends of capillary expressed in feet of the fluid actually flowing, due account being taken of the effect of temp. and pressure; L = length of tube in feet; u = velocity of flow in ft./sec.; d = diam. of tube in feet; g = const. for acceleration of gravity; and f = so-called "friction factor"—the only arbitrary const. involved in the equation. A curve was obtained by the calibration of a large no. of flowmeters; the process can be reversed and the values from the curve used instead of the calibration when a flowmeter is desired, a series of calcns. requiring about 30 min. taking the place of a calibration requiring 3 or 4 hrs. with no sacrifice in accuracy. A table showing values obtained with air, H, CO_2 and CH_4, and the curve itself, are presented. W. C. Ebaugh

The vapor pressure of barium oxide. M. deKay Thompson and W. G. Armstrong. *Trans. Am. Electrochem. Soc.* **54** (preprint), 4 pp.(1928).—The vapor pressure of Ba oxide was measured between 1280° and 1470° by satg. a measured vol. of air with the vapor of the oxide, and detg. the amt. of oxide required: 1100°, 0.03 mm. Hg; 1200°, 0.12 mm. Hg; 1300°, 0.42 mm. Hg; 1400° 1.6 mm. Hg; 1500° 5.6 mm. Hg; 1600°, 20.0 mm. Hg; 1880°, 760 mm. Hg. C. G. F.

Porosity and permeability as characteristics of porous bodies. O. Philipp. *Chem. Fabr.* **1928,** 152–3; cf. Howe and Hudson, *C. A.* **21,** 2967.—An app. is described for detn. of permeability by measuring the vol. of air which passes through per sq. m. per

min. at a pressure of 25 mm. The results are compared for porous plates of the same thickness prepd. by binding particles of definite sizes with varying proportions of binder. B. C. A.

Experimental researches on the diffusion of hydrogen through nickel. VICTOR LOMBARD. *J. chim. phys.* **25**, 501–30(1928).—A description of an app. and procedures for accurately measuring the rate of diffusion of hydrogen through Ni under carefully controlled conditions. The rate of diffusion varies with the temp., and with the structure of the metal. It is not affected by the presence of water vapor or small quantities of oxygen. It varies as the sq. root of the H pressure, even when admixed with large quantities of N. It is inversely proportional to the thickness of the metal. From the standpoint of permeability to a gas two layers of the metal behave like a single layer with the same thickness as the two layers. J. S. REICHERT

Rapid and micro-determination of specific gravity. E. H. RIESENFELD. *Chem.-Ztg.* **52**, 641(1928).—For the detn. of sp. gr. of small quantities of liquids a simple letter scale is employed, graduated to read directly in sp. gr. The sample is placed in a pycnometer of about 5-cc. capacity, and the instrument is provided with a normal weight as a tare. When loaded with the pycnometer and normal wt. the pointer stands at 1.000. The sp. gr. can be read directly to one unit in the third decimal place, with an accuracy greater than that of a hydrometer and a speed greater than that with a Mohr sp. gr. balance. W. C. EBAUGH

The work of the International Bureau of Physical-Chemical Standards. III. Study of the physical constants of twenty organic compounds. J. TIMMERMANS AND F. MARTIN. Univ. de Bruxelles. *J. chim. phys.* **25**, 411–51(1928).—A continuation of the work previously reported (*C. A.* **21**, 1038–9) carried out with the same accuracy. The following data were detd.:

	B. p.	M. p.	d_{15}	d_{30}	n^{15}_{D}	Viscosity 15°	Viscosity 30°
Hexane	68.80	−95.1	0.66380	0.65055	1.37787	337	278

The m. p. and d. values for the 9th and the 13th compds. are for the racemic form In addn. n is given for He red, yellow, green and violet, and for H_{α}, H_{β} and Hg for most of the compds.; values for mol. refraction are also given. E. G. VANDENBOSCHE

Physical properties of liquids as functions of temperature. G. ANTONOFF. *J. chim. phys.* **25**, 497–500(1928).—The physical properties of a liquid when precisely measured show a discontinuity in their variation with the temp. This discontinuity is often very small but it is distinctly beyond the limit of exptl. error. For benzene the curve for the latent heat of vaporization between 100° and 210° shows a break at about 145°, and the d. curve for temps. between 0° and 130° shows a break at about 55°. These breaks are explained by the hypothesis that the elementary constituents consisting of complex aggregates of mols. undergo changes at relatively low temps. J. S. REICHERT

A simple method of determining absolute viscosity of paraffin oils, vegetable oils, lubricating oils, etc. P. E. RAASCHOU. *Dansk. Tids. Farm.* **2**, 134–9(1928).—An

app. for viscosity detns. is described and illustrated. The app. consists essentially of a waterbath, for const. temp. equipped with a hand stirrer and a thermometer. In this bath is suspended a medium-sized test tube containing the sample, a thermometer and a capillary tube, having 3 marks on its stem The size of the capillary is detd. by the approx. viscosity of the oil. At the upper end of this capillary tube is fitted a rubber bulb having an opening at its top. To make a detn. lower the capillary tube until the surface of the oil sample is at the lowest mark. Then by means of the rubber bulb draw oil up into the tube, until the level of the oil is above the highest, or 3rd mark. Release the finger covering the hole in the rubber bulb and with a stop watch note the time it takes for the surface of the oil to drop from mark 3 to mark 2. The abs. viscosity expressed in poiseuilles is given by $[\eta] = K.t$, where K is a const. detd. from a liquid of known viscosity and t = time in seconds. Effects of temp., adhesion of oil to walls of capillary, etc., are discussed. O. A. NELSON

The mechanism of exchanges in distilling and rectifying equipment. CH. MARILLER. *Chimie et industrie* Special No., 134–40(April, 1928).—A general discussion of the mechanism of the exchanges taking place in the trays of distg. and rectifying columns, the problems of distn. and condensation being considered as applications of the laws of equil. between 2 phases. The question of ebullition or non-ebullition on the trays of rectifying columns is gone into in detail, by taking into account the effects of the reciprocal solubilities of the vapors and liquid, the effects of salts or other compds. (*e g.*, glycerol in the case of the production of abs. alc.), and the effects of diffusion of the vapors into the liquid. M. concludes that the mechanism of the rectification of vapors is essentially the same as that of the removal of C_6H_6 or light hydrocarbons from gases by systematic washing in a suitable solvent. A. PAPINEAU-COUTURE

Simple graphical method for determining the course of the natural distillation process. H. BRANDES. *Chem. Fabr.* **1928**, 261–2.—The construction of a curve showing the relation between the percentages of alc. in the vapor and in the residual liquid in the flask during the course of distg. a mixt. of alc. and water without the aid of a fractionating column is described, and a geometrical construction is given for deriving from this curve a curve showing the percentage of alc. in the residue at any stage of the distn. B. C. A.

Freezing point of ethyl alcohol-water mixtures. D. N. TARASENKOV. *Z. angew. Chem* 41, 704(1928).—The f. ps. of mixts. of EtOH and water contg. from 5.1 to 74.7% of alc by wt. have been detd., the freezing-mixt. being contained in a Dewar flask. With higher concns. of alc. the soln. is too viscous for accurate measurement. The freezing curve indicates the sepn. of a cryst. hydrate. The following data are recorded, the figures in parentheses being wt.-% of alc.: (5.1) − 2.1°, (9.3) − 4.1°, (14.2) − 6.7°, (17.8) − 10.2°, (24.4) − 15.2°, (29) − 19.1°, (33.3) − 24.2°, (37.6) − 28.4°, (43.0) − 33°, (46.7) − 35.4°, (51.9) − 38°, (56.3) − 42°, (61.4) − 45°, (66.1) − 48°, (70.2) − 56°, (74.7) − 67°. B. C. A.

The surface tension of liquid metals. III. The surface tension of mercury. L. L. BIRCUMSHAW. *Phil. Mag.* [7], **6**, 510–25(1928).—The surface tension of Hg has been detd. by the method of max. bubble pressure. Investigations were made regarding the influence of the material of the tube used, the phys. condition of the surface of the end of the tube from which the bubbles are blown, and the nature of the gas used for blowing the bubbles. The effect of hanging the bubble on the end of the tube for various lengths of time and the time taken to blow the bubbles has also been examd. Glass tubes appear to give slightly higher results than tubes made of silica, and in the case of the latter it was found that roughening the ends (tips) of the tubes was essential before concordant results could be obtained. This did not appear to be necessary with glass tubes. The nature of the gas used for blowing the bubbles, with the exception of O_2, has practically no influence on the values found. Accurate results could not be obtained with O_2 when glass tubes were used, but with silica tubes concordant values were found. With one set of glass tubes used, hanging the bubble on the end of the tube for various lengths of time always resulted in a lowering of the figure found, and this lowering increased with the length of the time. With another glass app. this effect was practically absent. GEORGE GLOCKLER

Variation of surface tension of oils with the temperature. GEORGE WINCHESTER. Rutgers Univ. *Phys. Rev.* **29**, 911–2(1927).—The surface tensions of several oils were measured by the max.-bubble-pressure method at temps. up to nearly 300°. Below 150° the surface tension decreases faster than the temp. rises. No numerical data are given. W. W. STIFLER

The surface tension of mixtures of ethyl alcohol and water. I. K. I. ALEKSEEVA. *Z. physik. Chem.* **134**, 46–74(1928).—The surface tension of solns. of EtOH in H_2O vary-

ing in concn. from 87 to 99.7% at intervals of 0.1% was detd. by the method of observing the max. pressure in small bubbles. The surface tension was found to vary continuously with the concn. within the limits of exptl. error, namely 0.1%. The measurements are to be repeated with the mixts. under the influence of electromagnetic waves to see whether a stepwise variation will result analogous to the relation found by Colley (*C. A.* **4**, 15) for the index of refraction of electromagnetic waves. F. L. Browne

Studies in adhesion. III. Mixture of two lubricants. Millicent Nottage. Dept. of Scientific and Industrial Research, London. *Proc. Roy. Soc.* (London) **A118**, 607–16(1928); cf. *C. A.* **22**, 3812.—The lubricants used were palmitic acid and the paraffin $C_{30}H_{62}$, palmitic acid and cetyl alc., and $C_{30}H_{62}$ and phenanthrene. A clean steel cylinder was placed on a clean steel plate and warmed in clean air to above the m. p. of the lubricants. Melted lubricants were then allowed to be drawn into the cylinder by capillarity, a pool was formed, the temp. was kept const. until equil. was reached, the heat was then cut off and the lubricant allowed to crystallize and the joint was broken at 18°. M. p. and adhesion are plotted against the percentage of mols present. The adhesion of admixed substances for all compns is greater than of pure substance. At 3 palmitic: 1 paraffin there is a max. on the adhesion and a min. on the m.-p. curve. Palmitic acid + cetyl alc. shows 3 transitions in adhesion but only two in melting, the unpaired transition point probably corresponding to the presence of cetyl palmitate. Phenanthrene, + $C_{30}H_{62}$ shows a const. adhesion from 46.6 to 73.5 mol percent $C_{30}H_{62}$. More than this produces a fall. Values for adhesion are given in all cases and there are 12 micrographs of the lubricants S. L. B. Etherton

Determination of the surface area of adsorbers. Karl Horovitz. Rockefeller Inst. *Phys. Rev.* **29**, 617(1927).—Certain fatty compds. form unimol. layers covering the available surfaces. The results of the surface tension of Na oleate solns. show that it is adsorbed in a unimol. layer at the interface of 2 phases. By assuming this unimol layer of Na oleate is formed on every adsorber, it is possible to det. the adsorber area from the quantity of Na oleate adsorbed and the known dimensions of the Na oleate mol. The ring method was used to det the adsorption of Na oleate. The surface of different charcoals detd. by this method was of the order of some 100 per sq mg. charcoal, the comparative surface areas for charcoals of different origin being in good agreement with detns. by other methods and other investigators S. L. B. Etherton

Adsorption in binary systems. L. S. Lévy. *Compt. rend.* **186**, 1619–21(1928); cf. Townsend, *Compt. rend.* **186**, 55(1928).—Measurements of adsorption by MnO_2 from the binary systems Fe–Ni and Cu–Ni indicated that Freundlich's equation ($c = KC^m$) held for either one of the two substances if the concns. of the other were kept const. The consts. K and m were functions of the equil. concn. of the second substance. These consts. were evaluated graphically for the 2 systems. R. L. Dodge

Life history of an adsorbed atom of cesium. J. A. Becker. Bell Tel. Labs. *Phys. Rev.* **29**, 364(1927); cf. *C. A.* **21**, 2426.—At equil. the av. life of an absorbed atom is N/A, N being the no. of absorbed atoms and A the arrival rate. With the filament at 660° K. and the arrival rate that corresponding to Cs at 20°, the surface is covered and an atom remains on it for one sec. Atoms move from one part of the edge to the other. Atoms cover distances a million times their diam. L. D. R.

Selective adsorption from gaseous mixtures by a mercury surface formed in the mixture. M. L. Oliphant. *Phil. Mag.* [7], **6**, 422–33(1928).—Exptl. evidence is presented which indicates that an expanding Hg surface selectively adsorbs CO_2 from a mixt. of CO_2 with an excess of H_2 or A. The measurements show that within the limits of the exptl. error the CO_2 so adsorbed forms a monomol. layer over the surface of the Hg. George Glockler

Important factors in the study of adsorption from solutions. K. C. Sen. *Z. anorg. allgem. Chem.* **171**, 275–80(1928).—Adsorption by unit wt. of adsorbent is influenced by the quantity of adsorbent and by the initial concn. and the total vol. of soln employed. This is particularly the case when there is strong chem. affinity between adsorbent and adsorbed substance. R. L. Dodge

The influence of the volume of solution and the mass of adsorbent on the adsorption of arsenious acid by metal hydroxides. K. C. Sen. Allahabad Univ. *Z. anorg. allgem. Chem.* **174**, 75–81(1928); cf. preceding abstract.—The adsorption of As_2O_3 by $Zr(OH)_4$ was measured for vols. of soln. between 50 and 200 cc. and with amts. of hydroxide between 0.27 and 1.08 g. For the same final concn. of solute the adsorption per g. of adsorbent is greater the smaller the total vol. of soln. The amt. of adsorption per g. of adsorbent appeared to decrease as the amt. of adsorbent was increased although expts. on this point were not decisive. Similar results were obtained with Al and Cr hydroxides. R. L. Dodge

Influence of volume on the adsorption of arsenious acid by iron and aluminum hydroxides. K. C. Sen. Allahabad Univ. *Z. anorg. allgem. Chem.* **174,** 82–90 (1928); cf. preceding abstr.—The "consts." for the Freundlich adsorption isotherm for As_2O_3 on either Fe or Al hydroxide are not true consts. if the adsorption is measured with different vols. of soln. Therefore no particular theoretical significance can be ascribed to the adsorption isotherm consts. Adsorption of $CuSO_4$ or MnO_2 was very definitely influenced by the mass of the adsorbent, but no similar effect with As_2O_3 on Fe and Al hydroxides was observed. R. L. Dodge

The electrical condition of hot surfaces during the adsorption of gases. II. A nickel surface at temperatures up to 850°. G. I. Finch and J. C. Stimson. *Proc. Roy. Soc.* (London) **A120,** 235–46(1928); cf. *C. A.* **22,** 8.—The elec. charge on a Ni sheet was measured at various pressures and temps. when the Ni was exposed to vacuum, H, O, CO_2, detonating gas, H_2O, N, A and mixts. of these gases. The results support the hypothesis previously advanced to account for the charging of Au and Ag surfaces under the same conditions. The Ni sheet becomes electrically charged when heated *in vacuo* or in contact with a gas. The magnitude of the *in vacuo* charge depends on the temp. of the metal and its previous history. After normalizing the surface by 1 or more oxidations and reductions, the charge due to a gas is characteristic of the gas and dependent on the temp. but independent of the pressure. The Ni sheet becomes covered with an oxide layer when heated in O, but the oxidized surface has the same *in vacuo* charge as the reduced O-free surface. The value of the charge due to the reaction product of a mixt. of combining gases is identical, at all temps., with that due to the original mixt. A or N, dild. with 2% O, gives the full charge due to either one of the 2 gases. Five different ways that gas can be absorbed on a hot metal surface are described. R. L. Dodge

Adsorption phenomena in solutions. XII. Electroösmosis. Lidie Orlova. *Z. physik. Chem.* **134,** 345–52(1928).—A systematic study was made of the influence on the electroösmosis with respect to kaolin, a negative diaphragm, and to Al_2O_3, a positive diaphragm, of increasing concns. of different electrolytes, including acids, bases, and salts. For kaolin the curves of electroösmosis *vs.* electrolyte concn. exhibit more or less pronounced maxima, in agreement with other authors. For Al_2O_3 several of the curves have minima. At low electrolyte concns. the sequences of the curves seldom are the reverse of those for kaolin. The positively charged surface of Al_2O_3 is more easily discharged and therefore less stable than the negative surface of kaolin. At high concns. of electrolyte the sequences of the curves for kaolin and for Al_2O_3 are always the same, as would be expected from adsorption and coagulation behavior. The characteristic course of the curves can be explained in general by the coincidence of primary and secondary adsorption, the former increasing the surface charge and the latter decreasing it. F. L. Browne

Some properties of colloidal lead. Helen Quincy Woodard. Memorial Hosp., N. Y. *J. Am. Chem. Soc.* **50,** 1835–40(1928).—The concn. of stable colloidal Pb prepd. by the Bredig method is proportional to the current used and to the p_H of the soln. at the beginning of the dispersion. The concn. of Pb rises to a max. with increasing concn. of stabilizing electrolyte and then falls off again. Bredig colloidal Pb is compared with colloidal Au, Ag and Pt with respect to the relation between the amt. of metal disintegrated and the concn. of sol produced and to the settling under gravity. F. L. Browne

Nuclear silver hydrosols. A. Galecki and R. Kempf. *Roczniki Chem.* **8,** 40–3 (1928), cf. *C. A.* **21,** 3512.—The yellow nuclear hydrosol, Ag_p analogous to Zsigmondy's Au_p was prepd. by pouring into a 250-cc. Jena flask 100 cc. thrice-distd. water (Ag condenser) 1.5 cc. 0.1% $AgNO_3$, 0.5 cc. NH_3 (d. 0.925), heating to the b. p. and adding slowly dropwise 5–6 cc. of an ether soln. of yellow P. The sol is quite stable. When prepd. at room temp. it begins to fade on the 2nd day and is discolored after a few days. P restores the color only passingly. Both sols are perfectly amicroscopic, free from ions and light-sensitive. Cond. and cataphoretic migration velocity (neg. charge) show a definite decrease with the age. *N* and 0.1 *N* $BaCl_2$, $AlCl_3$ and $Al_2(SO_4)_3$ ppt. a jelly, more flaky or granular according to diln. It gradually turns gray. Au is not reduced when seeded with Ag_p. The latter can even instantly stop the usual reduction to Au_F. Ag solns. are reduced to Ag_F, by both Au_p and Ag_p. With the latter the dispersion is less, the stability greater. The proper no. of cc. Ag_p is added to 50 cc. thrice-distd. water, 25 cc. 0.1% $AgNO_3$, 0.5 cc. NH_3 s. g. 0.925 and 5.0 cc. 0.3% HCHO, and the mixt. is heated to 80° with const. stirring The bright yellow color with an azure-green fluorescence reminds of Grabowski's (*Ber.* **36,** 1215 (1903)) Ag sols. The stability is greater with fresh Ag_p. At room temp. the formation of Ag_F,

with fresh Ag_p takes 15 hrs., with an Ag_p 8 days old it hardly takes place. The sols are ion-free and light-sensitive. Cond. and migration velocity decrease with age. On standing several weeks to months sols prepd. with 1–20 cc. Ag_p gradually became turbid, lost the fluorescence and finally turned milky sepg. black Ag. Ag_{P_p} is less sensitive to electrolytes than Ag_p. MARY JACOBSEN

Colloid chemistry. XXIII. Physico-chemical investigation of thorium oxide sol. WOLFGANG PAULI AND ALBERT PETERS *Z. physik. Chem.* **135**, 1–23(1928); cf. *C. A.* **22**, 525.—Pure concd. ThO_2 sols, with Cl as contra-ion, have been prepd. by peptization in hot and cold soln. The Cl and ThO_2 contents have been detd. potentiometrically and measurements of the conductivities of the sols have been carried out. Sols obtained by hot peptization yield very low values for the activity of the Cl ion, an effect attributed to reciprocal interionic forces between the Cl ions and the colloid particles. The activity coeffs. and the diln. equiv. cond. relationship exhibit marked anomalies, which can be explained in terms of modern views, whereas the classical theory leads to very improbable values for the colloid-ion mobilities. Substitution of the contra-ion by the addn. of various Ag salts indicates that complex asymmetric univalent ions have a greater effect than simple ions in changing the activity coeff. B. C. A.

The use of tartaric acid in the preparation of electronegative sols. A. B. DUMANSKIĬ AND A. G. KNIGA. *J. Russ. Phys.-Chem. Soc.* **60**, 229–36(1928).—By warming 2 *N* *d*-$(CH(OH)CO_2H)_2$ with increasing amts. of SnO_2 and TiO_2, complexes were obtained of increasing mol. wt. D. varies linearly with the concn. of the oxides. The viscosity curve is slightly convex towards the concn. axis. α_D increases with the concn. of the oxide, more so in the case of TiO_2; abrupt changes of slope take place at 5 $C_4H_6O_6$ SnO_2 and 4C $H_6O_6.TiO_2$. Sp. cond. increases rapidly up to a concn. of 10–20 "millimols" per l. and then is practically const. F.-p. depression increases continuously with the concn., more so for TiO_2. Conclusion: Complex ions are formed, at first causing an increase in cond. and α_D; beyond a certain point their no. remains const. although the total no. of mols. grows, excess of the hydrated oxide being peptized by $C_4H_6O_6$. A Tyndall cone appears at this stage. A SnO_2 sol dialyzed until neutral contained 7 35 g. per l. and had the compn. $(SnO_2)_{243}$ $C_4H_6O_6$. The liminal values do not follow Schultze's rule. It is unchanged at 100°, but will not redisperse after freezing. SnO_2 is peptized by HCl, better by $H_2C_2O_4$ and most readily by KOH. Heating favors dispersion. BASIL C. SOYENKOFF

Silicic acids. IV. R. SCHWARZ AND H. RICHTER. *Ber.* **60B**, 2263–70(1927); cf. *C. A.* **19**, 941; **21**, 2624.—Fused mixts., corresponding in compn. with the formulas $Na_4Si_3O_8$ and $Na_2Si_3O_7$, become cryst. after long preservation at 500°, and then exhibit the radially arranged needles of a monotropic substance. They are, however, only mixts. of meta- and disilicate or disilicate and SiO_2, since the so-called granatic acid gives an x-ray spectrum very closely similar to that of disilicic acid, and its vapor-tension isotherms, like those of "trisilicic acid" (which appears to give an individual x-ray spectrum), do not give any indication of the presence of a hydrate of the required compn. Granatic and trisilicic acids cannot therefore be regarded as chem. individuals. The presence of definite hydrates is not shown by the vapor-tension isotherms of silicic acid gels obtained by cautious neutralization of 5% solns. of Na meta- and disilicates with HCl followed by thorough washing of the ppts. Dehydration of the gels by acetone under varied conditions results in the removal of water to a content of about 13%, thus indicating the presence of disilicic acid. Its production from Na metasilicate is explained by the displacement of the equil., $2Na_2SiO_3 + H_2O \rightleftharpoons Na_2Si_2O_5 + 2NaOH$, towards the right during neutralization with HCl. Addn. of $BaCl_2$ to solns. of Na meta- or disilicate or $NaHSiO_3$ results in the pptn. of a mixt. of Ba meta- and di-silicates; if a large excess of NaOH is present, homogeneous Ba metasilicate is pptd. Ba meta- and di-silicates are obtained from solns. of Li orthosilicate even in the presence of a large excess of LiOH. The SiO_3^{--} and $Si_2O_5^{--}$ ions appear to be only ones present in solns. of alkali silicates; they form an equil. which usually is largely in favor of the disilicate ion (cf. Hägg, *C. A.* 20, 3257). B. C. A.

Dispersoidological investigations. XVIII. Methods of obtaining fibrous precipitates of any substance; the structure of fibers in general and that of cellulose fibers in particular. P. P. VON WEIMARN, *et al.* *Repts. Imp. Ind. Research Inst. Osaka, Japan* **8**, 7–17(1927); cf. *C. A.* **22**, 873.—"Fibers" are defined as "aggregates of disperse particles whose length is several times the breadth and thickness." Any substance may be obtained in the fibrous form under suitable conditions, though the fibers may not be very strong or very durable. There are three ways of obtaining fibers: (1) pptn. of the substance from very concd. solns. of reagents in a medium in which it is practically insol., (2) pptn. under conditions favoring the formation of needle-shaped

crystals, and (3) aggregation of small rod-like particles into long fibers by the orienting effect of flowing in streams. Microscopic examn. of swollen and partly dispersed fibers of *cotton cellulose* show them to be made of concentric tubes of chem. different substances. The outer tube is a wax-like substance more resistant to reagents than the rest. The middle tube is predominantly cellulose but contains other admixtures. The inner tube, contg. the lumen is a plasmatic formation. There are transition layers between the tubes and the cellulose tube is itself further subdivided into a series of very thin tubes, the walls of which are made up of thin fibrils arranged parallel to each other along the length of the tubes. *Wood cellulose* fibers likewise consist of three concentric tubes of chemically different substances, the outer tube of which is more resistant to reagents. Somewhat similar results are reported by Ritter who worked directly upon wood fibers and tracheids. **XIX. "Pure" cellulose as a colloid.** *Ibid* 19–39.— Natural cellulose fibers have a superficial layer of fatty or waxy material that hinders dispergation in salt solns. and accounts for the differences in the ease of dispergation of different kinds of cellulose. By suitable mech. and chem. treatments the cutical layer can be removed, when the cellulose becomes easily dispersable. Raw cotton cellulose does not disperse in boiling, satd. NaCNS soln. but by prolonged extn. with petroleum ether, amyl alc., ethyl ether or xylene the cotton cellulose is rendered dispersable. Boiling for 18 hrs. in abs. xylene followed by 8 hrs'. extn. with ethyl ether gave a sample of cotton cellulose that was almost as rapidly dispersed in boiling, satd. NaCNS soln. as pure filter paper. A 1% soln. so prepd. formed a clear, transparent jelly on cooling. Cellulose cannot be considered pure until all cuticle and all of the inner layer of the fibers, representing walls of lumen, have been removed, and in addn. the structure of the fiber has been completely broken down by dispergation to remove admixtures. This can be done by pptg. cellulose from its dispersion in salt solns. by dilg. with water and purifying the ppt. by electrodialysis. **XX. Microscopic investigation of coarse-cellular or membranous jellies in polarized light.** *Ibid* 41–66.—Jellies of $BaSO_4$ were made by allowing $4N$ $MnSO_4$ and $4N$ $Ba(CNS)_2$ to interact and were then observed with the polarizing microscope between crossed nicols. Photomicrographs of the resulting "structures of vectorial aggregation" and "fluidal and streaming structures" are given. It is concluded that "no doubt whatever can arise regarding the aggregate-fluid-cryst state's being a perfectly universal state of matter." **XXI. The rubber-like state of matter in connection with a microscopic investigation of silk coagula in natural and polarized light.** *Ibid* 67–80.—Silk was obtained in the "aggregate-fluid-cryst. state" by pouring a strong soln. of natural silk in concd. aq. soln. of a "substance dispergator" into a soln. of a "substance aggregator." Photomicrographs of the resulting structures between crossed nicols are given. Silk solns. pass through a transition state in which they have the elastic properties of rubber. The examn. in polarized light indicates that the system then consists of fibrils in the form of spirals embedded in a very viscous liquid. On drawing out a thread the spirals stretch out into parallel threads which curl into spirals again on being released. A similar system of spiral fibrils in a viscous liquid is assumed for rubber and all substances having an elastic consistency. **XXII. Jellies and gelatinous precipitates, their classification, conditions of formation, structure, and industrial application.** *Ibid* 9, 13–196(1928).—"This paper is not a text-book on jellies. It is a systematic record of the chief results of many years' long exptl. and theoretical work on jellies." If a liquid assumes throughout its mass a half-solid, elastic consistency, keeping at the same time in more or less degree the former transparency, we may call the resulting system a typical jelly. Jellies are classified: (1) according to the method of formation as *network* jellies, like gelatin, that gelatinize uniformly throughout the mass, or *membranous* jellies that gelatinize only on definite interfaces between two liquids in the act of mixing; (2) according to the degree of dispersity of the primary particles as, in the case of network jellies, macro-, micro-, ultramicro- or subultramicro-cryst. jellies and in the case of membranous jellies ultramicro- or subultramicro cryst. jellies; (3) according to consistency as resin-like, paste, soft-elastic, or solid jellies (glasses); (4) according to concn. of disperse part; (5) according as they are temp.-reversible or temp.-irreversible. The necessary and sufficient conditions for the formation of membranous jellies are low soly. of the pptg. substance, high specific supersatn. or an equivalent condition, and absence of dispergating tendency. The less the soly. the longer the jelly lasts. A membranous jelly can sometimes be changed into a network jelly by shaking thoroughly. For the formation of network jellies the soly. must be low and the sp. supersatn. high, but in addn. there must be an abundant solvation of the surfaces of the disperse particles. The greater the solvation the lower the sp. supersatn. and the higher the soly. at which gelatination may take place. Illustrative

expts. with jellies of alk. earth metal sulfates in alc.-water mixts. are described. Network jellies and the walls of membranous jellies, when freshly formed, are as devoid of structure under the microscope or ultramicroscope as glass. On aging a granular structure may appear which is due to secondary aggregates of particles. Real colloidal jellies are in reality gatherings of ultramicro-crystals, which have more or less unorderly stuck together, and which by adsorbing and by taking into pores between them, have imbibed the mother soln. Illustration of this structure on macroscopic and microscopic scales are afforded resp. by a suspension of natural silk wadding in $MnSO_4$ soln. and by photomicrographs of coarse-disperse jellies of $SrSO_4$ in which the interlocking bundles of needle-shaped crystals can be seen. Substances sepg. as needle-shaped crystals form jellies much more readily than substances forming plate-shaped crystals. Mech. agitation may break down the structure of a jelly, reversibly if the torn parts can "heal" again, otherwise irreversibly. Gelatinous ppts. are intermediate cases between jellies and flocculent ppts. Gelatinous ppts. are made up of ultramicro-crystals with the surface layers strongly solvated either of themselves or by adsorption of other substances. Photomicrographs of gelatinous ppts. of Au are shown. Flakes of flocculent and gelatinous ppts. may be considered as secondary structure elements of jellies. F. L. Browne

The prevention of precipitation of some metal hydroxides from solution by sugars. K. C. Sen. Allahabad Univ. *Z. anorg. allgem. Chem.* **174**, 61-74(1928); cf. *J. Ind. Chem. Soc.* **4**, 117, 131(1927).—Cane sugar causes the peptization of the hydroxides of Zr, La, Y and U, when their pptn. from soln. by alkalies is attempted. Lactose and dextrose cause peptization of Zr and U, while levulose is effective with Zr, U and Y. The action of the sugars is sp. The min amt. of a sugar necessary to prevent pptn. depends on the vol. of soln. and amt. of alkali. The smaller the total vol. and the greater the alky., the smaller is the amt. of sugar necessary for peptization. Time also plays an important part. The influence of negative ions is also appreciable. R. L. Dodge

The protection of colloidal solutions. A. Boutaric. *J. chim. phys.* **25**, 120-41 (1928).—The protective influence of varying quantities of gum arabic, albumin, casein, starch, dextrin and gelatin on the stability of gamboge, mastic, and As_2S_3 sols in the presence of HCl, KCl and $BaCl_2$ has been studied. All types of action by the foreign substances are noted: protection, acceleration of flocculation, protection increasing with concn. of foreign substance to a max. with subsequent diminution, etc. The effect of "minute quantities" of electrolytes on these sols is also reported. The influence of the manner of addn. of the electrolyte is also investigated at length. No theoretical treatment whatever is attempted, and the results are reported in so diffuse a manner that it is impossible to abstract them. W. T. Richards

The behavior of some colloids toward iodine and the possibility of using it for the titration of colloids. Wilhelm Engelhardt. *Kolloid-Z.* **45**, 42-6(1928).—The purpose was to develop methods for detg. quant. the compn. of colloidal solns., *e. g.*, the proportions of colloidal metal and metal oxide in metal hydrosols. The behavior with (1) 0.1 *N* KI soln., (2) 0.1 *N* KI_3 soln., and (3) 0 1 *N* soln. of I in EtOH of the following colloids is described: Au sols prepd. by 14 methods, Ag sols (12 methods), Cu, Hg (5 methods), Cd, Zn, B, Pb, C, Bi (3 methods), Sb (2 methods), As (2 methods), Te, Se (4 methods), S (2 methods), Mn, Fe, Pt (4 methods), Pd (2 methods), Rh (2 methods). The following react promptly with I: Au, Ag, Cu, Hg, Cd, Zn, Pb, Bi, Sb, As and Te. Se reacts only with difficulty. The following do not react; B, C, S, Pt, Pd, Rh, Mn and Fe. A line may be drawn through the periodic table of elements dividing the elements that react with I from those that do not. Most metal sulfide sols react with I but most metal oxide sols do not. Those metal sols that react with I can be titrated provided that the course of the reaction can be governed and the end products recognized, and provided further that the colloid contains none of the reducing agent with which it may have been prepd. F. L. Browne

The colloid state of gelatin solutions and the influence of changes in temperature upon it. Max Frankel. *Kolloid-Z.* **45**, 355-66(1928).—Under mild exposure to temp. (incubator temp.) gelatin solns. undergo a profound change in colloid nature without change in chem. compn. The magnitude of the change depends upon the duration of the heating. The phenomenon is called dissociation. The decrease in viscosity, increase in diffusibility through membranes, and decrease in jelling power and optical rotation that accompany dissocn. were studied. In the action of pepsin on gelatin solns. of different degree of association the same end products always result, and the reactivity is greater the greater the dissocn. Gelatin solns. of const. proportions are obtained if the solns. are held at a const. temp. long enough. Under the con-

ditions employed this took 75 hrs. The influence of temp. is most marked between 5° and 40°. Const. proportions are reached more rapidly outside of these limits. A stable soln. is further dissociated on raising the temp. or associated on lowering it. Mild, temporary temp. changes are entirely reversible, but prolonged heating results in gradual changes of a permanent character. Solns. of different degree of association become more nearly alike on warming but differ again on cooling. F. L. Browne

The structure of gels. I. Colloidal solutions of a photopolymerization product of vinyl chloride that gives solid, waxy masses like vaseline, and jellies. Gilbert Flumiani. Univ. of Zagreb. *Kolloid-Z.* **45**, 152–5(1928).—Jellies of the photochem. polymerization product of vinyl chloride are simpler than those of such complex, indefinite substances as gelatin and agar and their study should therefore throw light on the general theory of jellies. The photoproduct of vinyl chloride gives transparent, elastic jellies in aniline, Peruvian balsam, rosemary oil, tetralin, $CHBr_3$ and $C_2H_4Br_2$ by swelling 24 hrs. in the liquid, melting at 80°, and cooling. Concd. jellies are optically empty in the ultramicroscope, dil. jellies show ultramicrons arranged in an orderly manner that increase in size on further diln. and slowly coagulate when the system is dild. to the fluidity of a sol. In castor oil, cedar oil, aged French turpentine, pine oil, camphor, and copaiba balsam it can be incorporated in much the same way but at somewhat higher temps. and gives masses that are waxy at high concn. and vaseline-like when more dil. Under the ultramicroscope they exhibit coarser micelles, irregularly distributed, that do not increase in size on further diln. The elastic jellies are held to be characterized by very high dispersity and by a state of tension between particles and dispersion medium. F. L. Browne

Plasticity. IV. Plastic materials from silica. Otto Ruff and Bruno Hirsch. Tech. Hochschule, Breslau. *Z. anorg. allgem. Chem.* **173**, 14–26(1928); cf. *C. A.* **18**, 1596.—A quartz contg. 98.8% SiO_2 and having a particle size of 2–8μ was used. By prolonged treatment with acid, washing, grinding, centrifuging, dialyzing and rapid drying *in vacuo*, samples of high purity and with a particle size of 1.2$\mu\mu$ (av. for sample A_3) were obtained. Samples of 50 g. each of these silica prepns. of varying particle size were treated with NaOH, HCl, HNO_3, H_2SO_4, $(COOH)_2$, H_3PO_4 and CH_3COOH in several concns. The samples treated with alkali did not mold satisfactorily, *i. e.*, cracks developed and the body adhered to the mold. Treatment with HCl gave much better results. In general, the finer particle size and the higher concn. of acid produced better molding qualities (plasticity, and min. shrinkage). Under similar conditions, treatment with HCl and HNO_3 of the same concns produced similar results. Bodies molded from slips treated with the other acids were not as satisfactory, showing that the H-ion concn. is the important factor. The effect of neutral salts in analogous treatment shows that the H-ion concn. as detd. by anions of the salts is here again the controlling factor. Neutral slips produced bodies that did not crack, provided the particle size was sufficiently small (1.2μ). Improvement in plastic properties is ascribed to adsorption of H^+. The actual amt. of H-ion adsorption was small and it was not established with certainty. The swelling effect increased to a max. at the highest concn. of HCl used. (6 *N* was obtained by passing in HCl gas.) The H-ion concn. of the superficially hydrated SiO_2 is p_H 4.85. The observations are explained on the assumption of a diffusion equil. of the mobile H-ion between the interior of the quartz grains and the dispersion medium and a hypothetical formation of polar mol. groups at the surfaces of the quartz particles ("cover formation"). This hypothesis is discussed in detail. A. J. Currier

The influence of salts on the viscosity of flaxseed mucilage. M. S. Dunin and F. M. Shemyakin. *Kolloid-Z.* **45**, 146–52(1928).—The aq. soln. of the mucilaginous material from flaxseed hulls has a high viscosity—relative viscosity 3.20 in 0.16% soln. The viscosity is decreased by addn. of NaCl, KCl, $CaCl_2$, Na_2SO_4, K_2SO_4, $NaNO_3$ and KNO_3 in concns. from 0.04 to 0.2 *N*. $MgSO_4$ decreases the viscosity in concns. from 0.001 to 0.1 *N* and increases it slowly at higher concns. K_2SO_4, $(NH_4)_2SO_4$, $ZnSO_4$ and $CaCl_2$ exhibit the rise in viscosity at higher concns. less markedly than $MgSO_4$. The special behavior of $MgSO_4$ is attributed to the influence of Mg on the swelling of plant colloids. F. L. Browne

The role of dielectric constant, polarization, and dipole moment in colloid systems, especially in non-aqueous dispersoids. I. Wo. Ostwald. *Kolloid-Z.* **45**, 56–82 (1928).—The dielec. const. plays a very important part in disperse systems composed of poorly conducting org. materials, but for the understanding of such systems account must also be taken of density, and refractive power, which together with the dielec. const. enter into the expressions for polarization and dipole moment according to modern theories of the dielec. structure of matter. A summary of these theories, particularly

of Debye's, is given. The important concepts and magnitudes are defined and methods of measuring them given. The data for about 250 substances, mostly org. liquids, are collected, partly from the literature and partly from new measurements. The discrepancies between the dipole moments obtained by different methods are discussed, especially the "single moments" (observed in vapor and dil. soln.) and "mass moments" (observed in the liquids). Simple hydrocarbons usually show slight orientation polarization. Halogenated derivs. exhibit marked dipole moments, especially in *o*- and *cis*-positions, but compds. like CCl_4 show little polarization. In alcs. the moment increases with the no of CH_2 groups. Aldehydes and ketones are characterized by high moments, ethers, amines and N bases by moderate moments Nitriles, cyanides and thiocyanates have high moments. Data for fatty acids are incomplete but the moments are greater than 1. In the chloroacetic acids the moment decreases with increasing no. of Cl atoms. Esters have moments between 1 2 and 2 0, increasing in homologous series. Mercaptans have marked moments but CS_2 a very small one. Highly associated liquids like H_2O, $C_6H_5NO_2$ and acetone vary greatly in the moments obtained by different methods, for example H_2O from 1.8 to 0.8 The highest moments known are for NO_2 compds. The different polarization magnitudes are plotted against dielec. const. For most of them, especially for the dipole moments, there is a marked max. at an intermediate value for the dielec. const. Liquids with a d. of about 0.8 occupy an exceptional position. Problems of dispersoid chem. for which the polarization magnitudes will be helpful are reviewed briefly. II. **The stability of weakly solvated, pure organosols.** *Ibid* 114–22.—A theory is advanced to account for the stability of metal organosols prepd. by the Svedberg elec. dispersion method The orientation polarization of the dispersion medium is the chief factor in the stability. Electrolytes play no part in these purely org. sols. The influence of traces of H_2O on chem. and colloid chem processes, for example in Baker's extremely dry liquids, is discussed. III. **The behavior of organosols containing electrolytes.** *Ibid* 331-45.—Although Errera's Pt alcosols contain some water and impurities, the orientation polarization plays an important part in their stability just as in the case of very pure organosols. All substances whose addn. does not tend to coagulate have high dielec. consts. and high dipole moments and the strongest coagulants are liquids having no, or only weak, dipole moments such as C_6H_6, C_6H_{14} and CCl_4 Errera's sulfide alcosols, which contain electrolytes, exhibit different behavior in that substances of high dipole moment like amyl alc. may coagulate and C_6H_6, C_6H_{14} and CCl_4 have a max coagulating effect at an intermediate concn. There is no min. in dielec const. of the mixts of alc with these liquids but there is a max. in the mol polarization of alc. in a dipole-free soln. corresponding to the optimum coagulation. The sulfide particles in the alcosols are in adsorption equil. with the electrolytes present, the adsorbed layer contg not only ions but alc. dipoles. It is not to be regarded as a solid double layer but as a diffuse "ion and dipole atmosphere" in the sense of Gouy, Debye, Huckel, etc. Addn. of other org. liquids results in desorption of ions below the stabilizing concn. and thus in coagulation. Theoretically there is a connection between adsorbability and dipole content corresponding to that between dipole content and soly. F. L. BROWNE

The electrochemistry of colloids. I. Electrochemical properties of silicic acid. ADOLPH I. RABINOVICH AND E. LASKIN. *Z. physik. Chem.* **134**, 387–405(1928).—SiO_2 sols were prepd. by Graham's method, electrodialyzed and concd. to 0.25 to 0.53% SiO_2. The sols were strongly acid with p_H as low as 3 23. The total amt of H^+ titrable with NaOH was detd both conductimetrically and potentiometrically. The free-H-ion concn. was also detd. by both methods. The values for total titrable H-ion detd. in the 2 ways agreed exactly those for free H^+, though not in exact agreement, were reasonably consistent. The dissocn. const. for colloidal H_2SiO_3 detd. from the form of the potentiometric titration curve was 2×10^{-4}, which is much higher than the dissocn. const. for truly dissolved H_2SiO_3, namely 10^{-9}. This is analogous to phenomena previously observed in As_2S_3 and mastic sols. The higher dissocn. const. of the colloidal form may be due to weakening of the bond between H^+ and SiO_3^{--} as a result of the forces of adsorption holding the SiO_3^{--} ions on the colloidal particle On dilg. SiO_2 sol further dissocn of H^+ takes place, giving the sol buffer characteristics The total titrable H^+ also increases on diln., indicating that some of the inner SiO_2 mols. in the colloidal particles become hydrated, that is, the SiO_2 hydrolyzes. F L B

The measurement of the electrokinetic potential on proteins by the streaming-potential method. DAVID R. BRIGGS. Univ. of Minn. *J. Am. Chem. Soc.* **50**, 2358-63 (1928).—"The streaming-potential method of measuring electrokinetic potentials was applied in a study of egg albumin by utilizing the property of the protein to adsorb on to a quartz surface so as to give that surface the properties of the protein. Data, upon

comparison with the work of Abramson with the same protein on quartz surfaces but by the cataphoresis method, show excellent agreement between the values of the zeta-potential obtained by the two methods between p_H 3.8 and 5.2. Divergence of the values of zeta-potential beyond this range is explained by the differences in the concn. of the electrolyte utilized in the two expts. and probably, to some extent, by the differing effects of the ions used." F. L. Browne

The solubility of aluminum bromide in carbon disulfide. H. H. Kavelér and C. J. Monroe. Mo. School of Mines and Met. *J. Am. Chem. Soc.* 50, 2421–6(1928). —Methods for the synthesis of large amts. of $AlBr_3$ (by Richards method, *C. A.* 15, 195), for sampling satd. solns. at const. temp., and for the analysis of anhyd. $AlBr_3$ are described. The $AlBr_3$ was prepd. from C. P. Al, and Br purified by distn. from chromic acid, KOH and KBr. The CS_2 used was shaken with Hg, distd. from anhyd. $CaCl_2$ and stored in contact with P_2O_5. The soly. of $AlBr_3$ in CS_2 was detd. for the temp. range: 0.1° to 85.0°, a few of the data being: 0.1°—17.0 mol. % $AlBr_4$; 20°—28.9; 30°—36.2; 50.1°—54.5; 70°—73.1; 81°—83.3; 85°—87.8. The high soly. of $AlBr_3$ in CS_2 is shown to be in accordance with the several rules derived from general hypotheses of soly. The soly.-temp. curve shows a change of slope between 70° and 71°, indicating the existence of 2 modifications of $AlBr_3$, which confirms previous work, Kendall, Crittenden and Miller (*C. A.* 17, 1914). Dil. solns. of $AlBr_3$ in CS_2 have conductivities more than 1000 times that of pure CS_2, although the solvent is a poor ionizing agent. J. H. P.

The constitution of magnesium acetate solutions. II. Evidence from vapor pressures. E. A. Goode, Noel S. Bayliss and Albert C. D. Rivett. Univ. of Melbourne. *J. Chem. Soc.* July 1928, 1950–5.—To explain the relations between concns. and viscosities, f. ps. and conductivities of solns. of Mg acetate in water, polymerization at higher concns. has been postulated (*C. A.* 20, 2794) as chelate ring formation where the Mg atom exercises a coördination no. of 4. This view is fully substantiated by vapor-pressure data at 25° obtained by the McBain and Salmon modification of the Cumming dew-point method. G. L. Clark

Viscosity measurements and the nature of the solutions of a few hydroxides in potassium and ammonium hydroxide. K. Mohanlal and N. R. Dhar. Allahabad Univ., India. *Z. anorg. allgem. Chem.* 174, 1–10(1928); cf. *C. A.* 20, 1158, 2141.—This is a study of the solns. of the hydroxides of Al, Cr, Sn, Zn, Pb, Be, Cu, Cd and Ag in KOH and NH_4OH, with the object of detg. whether they are true solns. or contain the hydroxides in colloidal form. To this end, viscosity measurements are made in N and 0.5N KOH and in N, 2N and 5N NH_4OH solns. at 30°. The viscosity of N KOH is 0.008954 and 0.5N KOH is 0.008462, while for the solns. of the metallic hydroxides the following results are obtained: In N KOH: M/40 Al_2O_3, 0.009055; M/9 ZnO, 0.009243; M/18 ZnO, 0.009153; M/42 Cr_2O_3, 0.009265; M/19 BeO, 0.009022; M/11 BeO, 0.009093; M/11.5 SnO_2, 0.009000; M/7 SnO_2, 0.009124; M/13.1 PbO, 0.009008; in 0.5N KOH: M/100 Al_2O_3, 0.008534; M/84 Cr_2O_3, 0.008943; M/38 BeO, 0.008509; M/13 SnO_2, 0.008502; M/19.7 PbO, 0.00853. The viscosity of N NH_4OH is 0.008211, 2N is 0.008360 and 5N is 0.008694, while the viscosity of the hydroxide solns. is as follows: In 2N NH_4OH: 0.22 g. CuO/100 cc., 0.008582; 0.1344 g. CdO/100 cc., 0.008421; 0.221 g. ZnO, 0.008495; 1.717 g. Ag_2O, 0.008631. The elec. cond. of similar solns. is also measured, the soln. of the metallic hydroxide showing decreased cond. Thus when 2.2 g. SnO_2 is dissolved in 100 cc. N KOH, cond. is diminished 13% and when 0.448 g. ZnO is dissolved in 100 cc. N KOH, cond. is reduced 7%. To obtain comparative values with acids which form true solns., viscosity and cond. are measured on addn. of HCl, boric and benzoic acids to KOH. Thus on adding M/3.6 boric acid to N KOH; viscosity is 0.009495 and sp. cond. is 0.1577; on adding M/18.5 benzoic acid to N KOH, viscosity is 0.009037 and sp. cond. is 0.2002; on adding 2.34 g. HCl to 100 cc. N KOH, viscosity is 0.008694. Conclusion: The hydroxides of Be, Al, Cr, Zn, Sn and Pb in KOH and the hydroxides of Cu, Cd, Zn and Ag in NH_4OH are partly present in a colloidal condition. The decrease in elec. cond. is explained as due to the adsorption of alkali by the hydroxide for its peptization and the replacement of OH ions by aluminate, chromite, stannate and similar ions. H. Stoertz

Crystallization of a metal from a solution of its salt. C. C. Kiplinger. Alliance Inst. of Applied Chemistry, Alliance, O. *J. Chem. Education* 5, 964(1928).—Thirty grams of powdered Sn, free from As, Cu and Zn, but with small traces of Pb and Fe, was covered with 50 cc. of concd. HCl. After at least 48 hrs. an equal vol. of H_2O was added. This was allowed to stand for a couple of hrs. and when observed at the end of this period showed long needle-like crystals growing out of the excess of Sn. On pouring off the $SnCl_2$ soln. and re-subjecting the excess of Sn to the action of a fresh

supply of HCl, etc., on diln. the crystals grew rapidly, reaching a length of 1 cm. in 5 min., and increasing to 3-4 cm. in about one hr. W. C. EBAUGH

Solubility of diethyldiphenylurea in water, in alcohol and in other organic solvents. LOUIS DESVERGNES. *Ann. chim. anal. chim. appl.* 10, 226-8(1928).—At 0°, 20°, 50° and 85°, 3, 8, 12 and 30 mg. of this substance dissolves in 100 g. of water. In 100 g. of pure alc. 72.67 and 515.2 g. dissolves at 20° and 50°, resp. If the alc. is less than 72° and when the temp. is above 50°, there are 2 layers of soln. formed with markedly different contents of solute. Soly. data are also given when the solvents are EtOAc, AcMe, MeOH, benzene, $CHCl_3$, Et_2O, pyridine, CS_2, CCl_4, toluene and *m*-xylene. W. T. H.

Researches on the theory of hydrates. E. N. GAPON. *J. chim. phys.* 25, 154-6 (1928).—The properties of hydrates are additive. The properties of 42 hydrates are compared by an empirical equation. It is concluded that the density of water in hydrates is not greater than that of ice. W. T. RICHARDS

Cryoscopic irregularities with phenols. GEO. M. RICHARDSON AND PHILIP W. ROBERTSON. Victoria Univ. College, Wellington, New Zealand. *J. Chem. Soc.* 1928, 1775-83.—The van't Hoff equation, $K = 0.02T^2/L$, does not hold for a series of alcs., phenols, anilines, anilides, amides, pyridine and quinoline, in phenol soln. The observed deviations seem to depend on internal pressure and polarity in accordance with the theory of Hildebrand. Derived phenols show in the binary mixts. marked divergencies not traceable to these causes. The present theories of solid solns. and of activity are unsatisfactory, though some theory of activity is required. A general relation is shown between changes in mol. vol. upon soln. and cryoscopic behavior, in agreement with deductions drawn from internal pressure data. *Densities* of phenols and other compds. were accurately detd. at 40° as follows: AcOH 1.0291, iso-Am acetate 0.8524, Et malonate 1.0349, allyl alc. 0.8166, benzyl alc. 1.0303, phenol 1.0586, *o*-cresol 1.0290, *m*-cresol 1.0184, *p*-cresol 1.0186, *o*-chlorophenol 1.2416, *p*-chlorophenol 1.2651, toluene 0.8498, *m*-xylene 0.8487. G. L. CLARK

The conductivity and viscosity of solutions of lithium nitrate in certain mixed solvents. J. L. WHITMAN AND S. R. SPENCER. *J. Am. Chem. Soc.* 50, 1840-4(1928).—The conductivities and viscosities of $LiNO_3$ in water, MeOH, EtOH and various mixts. of these solvents have been studied at 25°. A pronounced min. occurs in the cond.-compn. curve only for $MeOH-H_2O$ mixts. It is found difficult to account for this in terms of viscosity. The difficulty in drying $LiNO_3$ may have been a source of error in previous work. W. T. R.

The absolute hydration of H, Li, Na, K, Cl and Br ions in their normal solutions. J. BABOROVSKY, J. VELISEK AND A. WAGNER. *J. chim. phys.* 25, 452-81(1928).—The electrolytic transport of H_2O in the presence of a parchment membrane was studied for solns. of bromides and iodides. The following values were found for the true transference no. of the cation $(1 - N)$ and the no. of g. mols. of H_2O transported by 1 faraday (Ξ):

	1.02*N*-NaCl	1.03*N*-KCl	1.02*N*-LiCl	*N*-NaBr	*N*-KBr	*N*-LiBr	*N*-HCl
$1 - N$	0.395	0.498	0.316	0.399	0.483	0.327	0.874
Ξ	0.90	0.47	1.62	1.58	0.89	2.10	0.43

The effect of electroosmosis on the above values is thought to be negligible. The abs. ionic hydration calcd. are given in *C. A.* 22, 12. E. G. VANDENBOSCHE

The apparent hydration of ions. I. Densities and viscosities of saturated solutions of sodium and potassium chlorides in hydrochloric acid. JOHN W. INGHAM. Heriot-Watt College, Edinburgh. *J. Chem. Soc.* 1928, 1917-30.—The solubilities, ds. and viscosities have been detd. at 25° of K and Na chlorides in aq. solns. of HCl of concns. varying between 0 and 13.5 *N*. Complete dissocn. of acids and salts being assumed, a formula is developed connecting ds. with ionic concns., ionic soln. vols. and apparent d. of H_2O in the solns. This formula is used to calc. soln. vols. Solns. of equal Cl-ion concn. up to 9 *N* have either lower or higher viscosities than solns. of HCl alone according as they are satd. with KCl or NaCl. The soln. vols. deduced from ds. account for the viscosities of HCl alone and of KCl-HCl. No hydration of Cl-ions is indicated and the K-ions are hydrated only to a slight extent if at all. H-ions may be present as H_3O^+ but are probably not more highly hydrated. A hydration factor of about 2 is necessary to account for viscosities of NaCl solns. G. L. CLARK

The variation of the capillary action of solutions with time. H. M. TRIMBLE. Univ. of Michigan. *J. Phys. Chem.* 32, 1211-24(1928).—The conclusion of Washburn and Bigelow (*C. A.* 22, 2697) that the variation with time in the capillarity of binary solns. is due to a change in the concn. caused by the preferential evapn. of one

component is confirmed. The capillary rise of the solns.: CS_2-toluene, Et_2O-CCl_4, Me_2CO-toluene, Et_2O-toluene and Et_2O-Me_2CO were measured at 25° in glass tubes, the radii of which varied from 0.162 mm. to 2.54 mm. The solns. had a concn. of 0.5 mole fraction. The rate and magnitude of the change with time depends upon the size and length of the tube, being greater the less the tube length and the smaller the tube. When these factors are const. the nature of the change may be predicted roughly from a knowledge of the surface tensions, volatilities and ds. of the components of the soln. *E. g.*, with Et_2O-CCl_4 soln., because of the evapn. of the Et_2O leaving a liquid with higher surface tension, the height of the meniscus gradually increases with time. It then reaches a max. and decreases because of the increase in the d. of the soln. Convection currents which carry the liquid downward near the wall of the tube and upward in the center exist in the capillaries and hasten the evapn. The quantity of liquid lost, however, is very small. The results show that evapn. must be completely prevented if reliable data upon the surface tension of mixts. contg. 1 or more volatile components are to be obtained. H. F. JOHNSTONE

A study of superacid solutions. III. The titration and dilution curves of bases dissolved in acetic acid. NORRIS F. HALL AND TYRRELL H. WERNER. Harvard Univ. *J. Am. Chem. Soc.* **50**, 2367–86(1928); cf. *C. A.* **22**, 527.—Diagrams and tables are given which show the effect of the following influences on the shape of the titration curves of bases dissolved in AcOH: the nature of the titrating acid ($HClO_4$, H_2SO_4, HCl), the concn. and the strength of the base. The weaker bases give anomalous titration curves while the curves of bases which act like strong bases in H_2O conform to the theory of such titrations. The effect of diln. on the H-ion activity of solns. of bases were studied by the e. m. f. method and even the "strongest" bases are truly weak electrolytes in this solvent. The results demonstrate the effective constancy of the liquid junction potential between satd. aq. KCl and the various AcOH solns. used. The value of the e. m. f. method in studying the effect of diln. on dissocn. is emphasized. E. R. SMITH

The influence of the solvent on the mobility of electrolytic ions. R. T. LATTEY. *Phil. Mag.* [7], **6**, 258–70(1928).—The evidence adduced in favor of the application of Stokes's law to the motion of ions in a liquid is of various kinds, but the two main propositions put forward by L. in its favor are: For certain salts $\lambda_0\eta$ is approx. independent of the solvent. For a somewhat larger class of salts $\lambda_0\eta$, though different in different solvents, is approx. independent of temp. in a given solvent. However, in the majority of cases $\lambda_0\eta$ only approximates to constancy in solvents whose dielec. const. is low; for solvents like water, for which the dielec. const. is high, larger values of $\lambda_0\eta$ are found. It is thus suggested that $\lambda_0\eta$ is a function of the dielec. const. λ_0 = equiv. cond. η = viscosity. GEORGE GLOCKLER

The conductivity and state of ionization of aqueous solutions of hydrofluoric acid. MAURICE AUMÉRAS. *J. chim. phys.* **25**, 300–7(1928).—Pick (*C. A.* **7**, 297) obtained the const. value of 7.2×10^{-4} as the ionization const. for fairly concd. solns. of HF at 25°. From cond. measurements A. was unable to get a const. value but found the value less than that given by P. By the chem. method previously described (*J. chim. phys.* **24**, 24; cf. *C. A.* **21**, 3148), A. found the value of 16.7×10^{-4}. This is the correct value for the primary ionization, since the chem. method conceals all other equil. whereas such equil., as $(HF)(F)^-/(HF_2)^- = C$ affect the value calcd. from cond. measurements. E. G. VANDENBOSCHE

The cause of an error affecting conductivity measurements. MISS L. DE BROUCKERE. Univ. de Bruxelles. *J. chim. phys.* **25**, 294–9(1928).—One of the chief errors in measuring the cond. of solns. is due to the adsorption of solute by the Pt black of the electrodes. A cond. cell with freshly prepd. electrodes gave a change in cond. for *N*/100 NaCl from 1.189×10^{-3} to 1.181×10^{-3} mhos at 25° after 24 hrs. This same cell, filled with a new soln., gave a const. value of 1.189×10^{-3} mhos. When the electrodes were first placed in 0.01 *N* NaCl and then transferred to the cell filled with 0.1 *N* NaCl the cond. changed from 1.253×10^{-4} to 1.321×10^{-4} mhos after 24 hrs. The amt. of NaCl adsorbed detd. directly is almost identical with the amt. calcd. from the change in cond. Solns. of LiCl, KCl, $CuCl_2$ and $NiCl_2$ gave similar results. E. G. V.B.

Reduction potential of nicotinic acid. MASUZO SHIKATA AND ISAMU TACHI. *Chem. News* **137**, 126(1928); cf. *C. A.* **22**, 1894. G. CALINGAERT

Refractometric evidence relating to the condition of strong electrolytes in concentrated solutions. K. FAJANS, H. KOHNER AND W. GEFFCKEN. *Z. Electrochem.* **34**, 1–10(1928).—Previous work (cf. Fajans, *C. A.* **21**, 3539) is reviewed and discussed. Measurements of the refractivity of H_2SO_4 in solns. of concns. up to 95% have now been made. The refractivity falls slightly with increasing concn. up to 40 mol. %, but rises

gradually with further increase in concn. These effects are attributed, resp. to the processes (1) $SO_4^{--} + H_3O^+ = HSO_4^- + H_2O$ and (2) $HSO_4^- + H_3O^+ = H_2SO_4 + H_2O$. The conversion of the ion H_3O into water should increase the refractivity, but this effect is opposed by a larger decrease due to conversion of SO_4^{--} into HSO_4^- in (1) and by a smaller decrease due to conversion of HSO_4' into H_2SO_4 in (2). The actual changes in refractivity are very small. The general conclusion from refractometric evidence is that strong electrolytes are incompletely dissocd. in aq. solns. and that they differ only in degree from weak electrolytes, so that no sharp line of demarcation can be drawn between the two classes. The essential modifications of the classical theory which is necessitated by recent work lies in taking account of interionic forces in the quant. treatment of the subject. The recent work of Nernst (*C. A.* **22**, 342) and Naudé (*C. A.* **22**, 717) on heats of diln. leads to similar conclusions, but the refractometric data lead to the conclusion that at given concn. the degrees of dissocn. of LiCl and NaCl are of the same order of magnitude even up to 5*N*. The contrary conclusions of Nernst and Naudé are discussed. Bjerrum's theory of "ionic assocn." is also discussed and criticised. B. C. A.

Reduction potentials of pyridine. Masuzo Shikata and Isamu Tachi. *Chem. News* **137**, 133–4(1928); cf. *C. A.* **22**, 720. C. Calingaert

First dissociation constants of *s*-diphenylguanidine and *p*-phenylenediamine. P. Walden and H. Ulich. *Z. Elektrochem.* **34**, 25–8(1928).—The elec. cond. of very dil. solns. of *s*-diphenylguanidine in water of sp. cond. $0.4–1.2 \times 10^{-6}$ ohm^{-1} has been measured in a silica cell. Corrections for CO_2 in the water, for the electrostatic forces between the ions, and for the activity coeffs. of the ions are shown to be less than the exptl. error, and the first dissocn. const. of the base is found to be $(8.19 \pm 0.65) \times 10^{-5}$. It is said that the dissocn. consts. of bases can be accurately detd. by the cond. method provided that the cond. of the water is not greater than 5% of that of the solns. employed. Detns. of the H-ion concn. of the above solns. by electrometric or colorimetric methods gave only approx. values for the dissocn. const. but confirmed the order of its magnitude. From cond. measurements of more concd. solns. of *p*-phenylenediamine, its first dissocn. const. is found to be $(1.30 \pm 0.10) \times 10^{-8}$, in satisfactory agreement with previous detns. by the electrometric method. B. C. A.

The mechanism of homogeneous gas reactions. I. The effect of black-body radiation on a molecular beam of nitrogen pentoxide. F. O. Rice, H. C. Urey and R. N. Washburne. Johns Hopkins Univ. *J. Am. Chem. Soc.* **50**, 2402–12 (1928).—In the usual methods for studying reactions, the 3 factors which influence the decompn. are: the absorption and emission of radiation, intermol. collisions, and collisions with the walls. The first effect is isolated by allowing a mol. beam of N_2O_5 to pass through a furnace, within which approx. black-body radiation is maintained. The second effect is isolated by allowing 2 beams to impinge, although this was found impractical for expts. with N_2O_5 because the total no. of collisions is small and only a small fraction of this no. would result in active mols. The third effect is isolated by allowing the beam to impinge on a heated surface from which it is reflected to a surface cooled to liquid-air temps. Expts. on the effect of black-body radiation indicate that no decompn. occurs. The probability of absorption of radiation by the N_2O_5 mol. is calcd. and found to agree with expt. J. H. Perry

Homogeneous gas reactions at high concentrations. I. Decomposition of hydrogen iodide. Geo. B. Kistiakowsky. Princeton Univ. *J. Am. Chem. Soc.* **50**, 2315–32(1928).—The decompn. of gaseous HI has been studied at concns. ranging from 0.02 to 7 mols. per l. The rate of decompn. is bimol. throughout the whole concn. range and is not affected by intensive drying. At the higher concns. a correction for the vol. of the mols. is introduced in the calcn. of the no. of bimol. collisions. Calcns. of the rate of reaction indicate that the effective cross section of activated mols. in collisions leading to reaction are smaller than the av. kinetic cross section of mols. J. H. P.

The kinetics of the decomposition of calcium carbonate hexahydrate. B. Topley and J. Hume. *Proc. Roy. Soc.* (London) **A120**, 211–21(1928).—The velocity of the reaction $CaCO_3.6H_2O \rightleftharpoons CaCO_3 + 6H_2O$ was studied dilatometrically, and the temp. coeff. of the reaction measured between 0 and 25°. The increase in velocity with temp. was shown to be a true temp. coeff. of reaction rate. A kinetic mechanism involving the vibration frequency of ions in the calcite-hexahydrate interface is suggested. R. L. Dodge

Water concentration and the rate of hydrolysis of sucrose by invertase. J. M. Nelson and Maxwell P. Schubert. *J. Am. Chem. Soc.* **50**, 2188–93(1928).—The rates of hydrolysis of sucrose solns. by invertase were measured at 25° by observing the change in rotation of polarized light. The sucrose concn. was varied independently

of the H_2O by adding definite amts. of C_2H_5OH to the sucrose solns. The results indicate that the concn. of H_2O is the primary factor in detg. the velocity of hydrolysis when the concn. of sucrose is greater than 20%. The curve, velocity *vs.* sucrose concn., shows a max. at about 7% sucrose. This curve is the resultant of 2 effects (1) increasing formation of sucrose-invertase complex and (2) decrease in water concn. R. L. D.

The hydrolysis of sugar by acids—hydrogen-ion concentration and rate of hydrolysis. H. Colin and Miss A. Chaudun. *Bull. soc. chim.* **43**, 721–5(1928); cf. *C. A.* **21**, 1047, 3300; **22**, 1084.—No relation exists between the variations in the hydrolytic consts. of sugar solns. and the variations in the H-ion concns. When the salt of a strong acid, without a common ion, is added to the acid the rate of hydrolysis is increased, as is also the H-ion concn., but again the variations are not parallel. Hydrolysis cannot be considered as a monomol. reaction, due to the H-ions alone.
E. G. VandenBosche

Note on measurements of the rate of decomposition of nitrogen pentoxide at very low pressures. Albert G. Loomis and David F. Smith. *J. Am. Chem. Soc.* 50, 1864–9(1928).—The adsorption of N_2O_5 and the occlusion of O_2 on a Pyrex vessel at low pressures involves a considerable fraction of the total gas present. Previous experimenters who have disregarded this effect in measuring the rate of decompn. of N_2O_5 are therefore considered in error. W. T. Richards

The influence of intensive drying on the system: nitrogen peroxide–nitric oxide–oxygen. John Wm. Smith. Univ. College, London. *J. Chem. Soc.* **1928**, 1886–94.—When NO_2 is heated with P_2O_5 at least 3 reactions take place: an addn. compd., a dissocn. of NO_2 into NO and O to a greater extent than in moist gases, and a greater rate of decompn. of NO into its elements than normal, by catalysis from the large surface of P_2O_5. A temp. of 300° and prolonged heating favor the third reaction. NO_2 intensively dried at ordinary temp. did not dissoc to any extent to NO and O at 550° but at 620° it reverted completely to the normal form, probably because of a superficial decompn. of the glass. In the dried gas the polymerization of colored NO_2 to colorless N_2O_4 is retarded. G. L. Clark

Reactions in the solid condition at high temperatures. IV. Reaction between basic and acid oxides and carbonates and method of compound formation. Wilhelm Jander. Univ. of Würzburg. *Z. anorg. allgem. Chem.* **174**, 11–23(1928); cf. *C. A.* 22, 1085—When solid substances react, a reaction layer is first formed between the surfaces in contact and further reaction only proceeds as one or both components diffuse through this layer. This process is studied for the following reactions: $BaCO_3$ + WO_3, $BaCO_3$ + MoO_3, $CaCO_3$ + WO_3, PbO + WO_3, PbO + MoO_3, $BaCO_3$ + SiO_2. In each case the proportion of the 2 substances is varied over a wide range and the reaction mixt. is heated for several hrs. In the case of $BaCO_3$ and WO_3, $BaWO_4$ is the only compd. formed, a slight excess of WO_3 over that required always being found, due probably to the formation of a poly compd. and soln. of this in the normal compd. In the case of $BaCO_3$ and MoO_3, $BaMoO_4$ is likewise the only product, and here too an excess of MoO_3 is found, while in the reaction between $CaCO_3$ and WO_3 the compd. formed is $CaWO_4$ contg. a slight excess of WO_3. In the reaction between PbO and the acid oxides the normal tungstate and molybdate are formed, but the product now contains a slight excess of PbO, indicating its slight soly. in $PbMoO_4$ or $PbWO_4$. In the reaction between $BaCO_3$ and SiO_2 the reaction mixts. are heated from a few hrs. to 3 days at 950°. With an excess of $BaCO_3$ the principal product is the orthosilicate, while with an excess of quartz the metasilicate is the chief product. The results indicate that diffusion through the surface reaction layer is responsible for completion of the reaction, and this is made possible only by the soly. of one of the components in the compd. formed in the reaction. H. Stoertz

Neodymium selenate. John Albert Newton Friend and Arthur Albert Round. *J. Chem. Soc.* **1928**, 1820–2.—The formation of the following forms of Nd selenate are described: $Nd_2(SeO_4)_3$ anhyd., $Nd_2(SeO_4)_3.5H_2O$, $Nd_2(SeO_4)_3.8H_2O$, and $Nd_2(SeO_4)_3.12H_2O$. The Nd salt is intermediate in hydrate formation between the Pr and Sa salts. L. L. Quill

Action of fluorine on aqueous solutions of chromium and manganese salts. Friedrich Fichter and Ernst Brunner. *J. Chem. Soc.* **1928**, 1862–8.—The oxidizing effect of F in prepg. persulfates, perphosphates, etc., is reviewed, and is shown to be at least as great as that of the Pt anode. A theoretical discussion is included. The oxidation of Cr alum giving chromic acid, and the reduction of $K_2Cr_2O_7$ to chromic salts by the action of F is described, with an explanation of the apparently contradictory behavior. The oxidation of MnF_2 and $MnSO_4$ is described. MnF_4 could not be prepd. by this method, as is also the case with anodic oxidation. In all cases, F proved to be

at least as strong an oxidizing agent as a Pt anode, and the observations throw a new light on the mechanism of such oxidations. The relation between electrochem. and ordinary chem oxidation is shown. L. L. Q.

Thermal decomposition of ethane, ethylene, propane, and propylene. F. E. Frey and David F. Smith. Bur. of Mines *Ind. Eng Chem.* **20**, 948-51(1928).—The decompn. of C_3H_8 on a Ni catalyst takes place very rapidly at 350° and 400°, yielding C, a large amt. of CH_4, and some H. A Cu catalyst has little effect on C_3H_8 at these temps. At 568° a Pt catalyst has a slight decompg. effect, giving C, H_2, CH_4, C_2H_4, C_2H_6 and C_3H_6. SiO_2 has little catalytic effect on C_2H_6 at 575°, and the only decompn. products are C_2H_4 and H_2. Polymerization of C_2H_4 at 575° in SiO_2 yields C_3H_6, CH_4, C_2H_6 and higher hydrocarbons Under the same conditions C_3H_6 yields C_4H_8, CH_4, C_2H_4 and higher hydrocarbons. T. S. Carswell

Recent investigations in the field of heterogeneous catalysis. Walter Frankenburger. I G. Farbenind A.-G *Z. angew. Chem.* **41**, 523-31, 561-7(1928).—A bibliography of 287 references is included. E. H.

Influence of (area of) active surface of a nickel catalyst on the velocity of hydrogenation of oils. S. Józsa. *Z. angew Chem.* **41**, 767-71(1928).—The velocity of hydrogenation of neutral sunflower oil increases with concn. of catalysts for all the concns. used (1-10%). There is no apparent relationship between the reaction rate and the surface area of the catalyst, detd. by Mitscherlich's method, because, as the catalysts were prepd. in different ways, it was improbable that for catalysts with equal Ni content, the amt. of active Ni present was the same. In order to overcome this difficulty, a single catalyst was used, but its surface was varied by using it in conjunction with different carriers. A definite quantity of Ni formate was added to the oil, and 2% of active charcoal. Expts. were carried out to show that the charcoal acted only as a carrier, the catalyst being distributed over its surface. The carriers used comprised active charcoal, two varieties of animal charcoal, blood charcoal, infusorial earth, wood charcoal and pumice. It was found that the velocity of reaction was proportional to the surface area of the catalyst, so that the value of a catalyst can be found by detg. its surface area. B. C. A.

Disintegration of the nickel catalyst. E. Mashkilleison. *Oil & Fat Industry* (Russia) 1928, No. 1, 24-7.—Metallic Ni pptd. on infusorial earth was sent through a colloid mill in 8 different portions, and disintegrated for 20 min. to 2 hrs. and 20 min. The sample taken out after 20 min. was composed of particles between 0.004 and 0.12 mm., the grain gradually decreasing; it reached for the 8th sample 0.003-0.004 mm. A check on hydrogenation proved that the coarse catalyst was more efficient than the finely disintegrated one. *Conclusion:* The catalyst layer is removed from the filler when sent through the mill, decreasing the surface and the activity. To obtain a finer catalyst with a large surface the filler must be disintegrated as far as possible and then the catalyst pptd. A. A. Boehtlingk

Thermal decomposition of ammonia upon mixed surfaces of tungsten and platinum. Robert E. Burk. Cornell Univ. *Proc. Nat. Acad. Sci.* **14**, 601-2(1928); cf. *C. A.* **22**, 343.—Contact catalysts accelerate reactions by lowering the heat of activation of the reactants. This effect could be produced (1) by distorting the atoms with a resulting weakening of the relevant bond, or (2) by bodily sepg. the atoms forming the bond. Previous expts. designed to study the importance of mechanism (1) were not completely satisfactory. The second mechanism was tested by measuring the velocity of decompn. of NH_3 on filaments having a mixed surface of W and Pt. Not only did the mixed surface cause a greater velocity of decompn. than the same area of either Pt or W alone, but the temp. coeff. was decidedly smaller for the mixed surfaces. Since W probably adsorbs N more strongly than H, and since the reverse is probably true for Pt the results are in complete agreement with expectations on the basis of mechanism (2). R. L. Dodge

The negative catalysis of autoxidation. Antioxygenic activity. (Messel memorial contribution.) Charles Moureu and Charles Dufraisse. *Chemistry and Industry* **47**, 819-28(1928).—Antioxygenic activity (neg. catalysis) is the inhibition of oxidation and pro-oxygenic activity (pos. catalysis) is the acceleration of oxidation. Antioxygenic activity has been shown to be a common phenomenon that is of fundamental concern in nature. Phenols retard the transformation of acrolein into disacryl, *e. g.*, 1 part of hydroquinone per 10,000 acrolein. The addn. of a trace of pyrogallol renders O_2 inert toward a third substance which itself is easily oxidized when pure. The direction of the catalysis, pos. or neg., is dependent on the conditions of the expt. and not on the nature of the catalyst, *e. g.*, $MeNH_2.HI$ acts as an antioxygen toward C_6H_5CHO, but as a pro-oxygen toward styrene; ethylxanthamide inhibits the

autoxidation of aq. Na_2SO_3 solns. if the latter are slightly alk., but accelerates oxidation if the solns. are slightly acid. The catalytic properties of a substance are related to its susceptibility toward oxidation, *e. g.*, P_4S_3, which is used in matches on account of its great reactivity toward O_2, acts as an effective antioxygen toward C_6H_5CHO at a diln. of 1 part per 1000. It has been shown that the catalytic effect is situated in that part of the mol. that is most easily oxidized. Any oxidizable substance, whether its reactivity toward O_2 is slight or considerable, should be an autoxidative catalyst under the proper conditions. I_2 and many I_2 compds. are positive catalysts (pro-oxygens) in the autoxidation of styrene and in the oxidation of linseed oil. Green MnS accelerates the autoxidation of C_6H_5CHO, and P_4S_3, C_6H_5SH and Sb_2S_3 accelerate that of styrene, while MnS, and C_6H_5SH accelerate the autoxidation of oil of turpentine and P_4S_3 that of linseed oil. Pro-oxygenic activities are generally not very intense, but some cases are noted where the velocity of autoxidation is increased more than 100 fold. I_2 is a strong antioxygen toward C_6H_5CHO, but is a pro-oxygen toward styrene; CHI_3 is pro-oxygenic toward styrene and an anti-oxygen toward furfurole; P_4S_3 is an antioxygen to C_6H_5CHO and a pro-oxygen to linseed oil; C_6H_5SH is an antioxygen to C_6H_5CHO and a pro-oxygen to turpentine: S and ethylene disulfide are antioxygens to Na_2SO_3 (1 to 10) when faintly alk. and pro-oxygens when slightly acid. In most such inversions of catalysis, the strongest antioxygen generally becomes the strongest pro-oxygen, *e. g.*, $CH_3NH_2.HI$ is a very active antioxygen to acrolein and is a pro-oxygen of the same order of intensity toward styrene. In the autoxidation catalysis of a substance the sign of catalysis often changes during the expt., *e. g.*, I_2 and its compds. are such catalysts; also, P_4S_3 is first an antioxygen and then a pro-oxygen toward turpentine. Thiophenol acts similarly toward linseed oil. The theory that autoxidation is due to a positive catalyst, and that it is possible to destroy its catalytic effect by the addn. of small quantities of other substances is of doubtful general validity. The inactivating action of hydroquinone on acrolein, if it exists, is insufficient to account for the observed antioxygenic activity. M. and D. offer the following explanation of antioxygenic activity: The peroxide, A (O_2), oxidizes the antioxygen, B, to the peroxide, B (O), while it is changed to another peroxide, A (O). The 2 peroxides, A (O) and B (O) are mutually antagonistic and destroy each other with the consequent regeneration of the 3 original components A, B and O_2 in their original state. The following facts prove that O_2 combined with acrolein, and not free O_2, is the agent which directly produces the change. If acrolein is freed from all O_2 by evacuation, its condensation proceeds just as in the presence of air, which indicates that the catalyst is not free O_2 and that mere contact with O_2 inoculates acrolein with a condensation agent. Further, the catalyst is not a volatile O_2 compd., because if the acrolein is partly distd. during condensation, it is found in the residue. If the acrolein containing a trace of an antioxygen, which prevents oxidation is exposed to air, no condensation occurs. Since it is not free O_2, it must be combined O_2 which catalyzes the condensation, and this combined O_2 must be a peroxide, either the primary A (O), or some product of it. Two types of antioxygens are stipulated: those possessing (1) a protective action and (2) those giving no effect. The reaction: $CH_3CHO \longrightarrow$ paraldehyde is not inhibited by antioxygens, and therefore O_2 does not cause this change. The polymerization of CCl_3CHO to metachloral is inhibited by antioxygens and here O_2 must cause the change. Furfural remains colorless when a trace of hydroquinone is added and therefore O_2 must be at least one of the causes for its discoloration. Since the drying of linseed oil may be inhibited by an antioxygen, O_2 must be the cause. *Ibid* 848–54.—The action of the natural antioxygens in raw *rubber* in protecting it from rapid destruction is fortuitously reënforced during its manipulation by antioxygens: (1) during smoking by the pyrogenic products of wood (pyrocatechol and derivs.); (2) during vulcanization with accelerators; and (3) by the addn. of "more oxidizable substances than rubber itself." These facts are addnl. evidence that the aging of rubber is due to oxidation. The problems of *knocking* and the action of *anti-detonants* are discussed and the anti-detonant and antioxygenic actions are correlated. Oxidations at high and low temps. resemble one another in that both are hindered by the same substances. C_2H_4, CO, and $(CN)_2$, which are negative catalysts in the combustion of H_2 with a Pt catalyst at ordinary temp., also prevent the explosion of the same mixt. by a spark. The film, screen, and buffer theories of anti-detonant action are tacitly rejected, for general applicability. The "poisoning" theory of the action of catalytic inhibitors (traces of gaseous inhibitors for a Pt catalyst) is rejected because these substances, which hinder the reactions in the presence of elec. sparks, cannot be spoken of as a "poisoning" of the spark. The "neutralization," the "direct inactivation" and the partial combustion theories are not of general application. Each of the theories is valuable only in a particular

example for which it is suggested. M. and D. state that the action of anti-detonants is that of antioxygenic catalysts which oppose the interaction of the fuel and the O. All previous theories have erroneously assumed that anti-detonant action occurs in the gas phase. The real seat of action is in the liquid phase and also that of the "knocking," especially in slightly volatile fuels. Anti-detonants hinder the formation of peroxide by an antioxygenic action. This theory is corroborated by: (1) the sudden elevation of the pressure, produced by knocking, is similar to that in the explosion of org. peroxides; (2) the production of a deposit of C during knocking is similar to the action of peroxides; (3) the increase of the elec. cond. of the combustion gases with the intensity of knocking which is a consequence of autoxidation; (4) conditions which favor knocking also favor autoxidation; (6) the "cold flames" of Perkins are a manifestation of autoxidation, and there is a close parallelism of the tendency of liquids to knock and their tendency to give the Perkin flames; and (6) the existence of pro-detonant activity is foreseen by the authors' theory of autoxidation. Combustible liquids autoxidize in the liquid phase to form peroxides which is demonstrable. Anti-detonants show an antioxygenic action in the autoxidation of heated autoxidizable liquids. In this autoxidation of heated substances the same catalyst may vary in its action toward different autoxidizable substances. Similarly, the same catalyst may be very effective for one fuel and almost inert, or even pro-detonant toward another. Small variations of the conditions may lead to the inversion of the action of the catalyst.

J. H. PERRY

Chemical interactions corresponding to the constant of mass action, being a function of the volume and masses of the constituents, as well as of the temperature and catalytic action. R. D. KLEEMAN. *Phil. Mag.* [7], **6**, 195-203(1928).—K. asserted previously (*C. A.* **22**, 308) that the const. of mass action is a function of the vol., mass and temp. of a reacting gaseous system. Now he obtains the further result that a dense substance in contact with a gaseous reaction of which it occludes to a certain extent one or more of the constituents, renders the const. of mass action a function of the vol and masses of the constituents. A catalytic agent thus is not only likely to change the velocities of the various changes continually going on in the reacting mixt., but the value of the const. of mass action as well, and to an extent depending on the vol. and masses of the constituents of the reacting mixt.

GEORGE GLOCKLER

Equilibrium constants of the reactions $CO + 3H_2 \rightleftharpoons CH_4 + H_2O$; $CO_2 + 4H_2 \rightleftharpoons CH_4 + 2H_2O$; and $2CO + 2H_2 \rightleftharpoons CH_4 + CO_2$. K. M. CHAKRAVARTY. *Z. Elektrochem.* **34**, 22-5(1928).—Consts for the above equilibria at temps. ranging from 800° to 1300° have been calcd (*a*) from the variation with temp. of the equil. consts. for $C + 2H_2 \rightleftharpoons CH_4$; $2CO \rightleftharpoons C + CO_2$; and $CO_2 + H_2 \rightleftharpoons CO + H_2O$, and (*b*) from the heats of reaction and the sp heats and chem consts. of reactants and products. The figures obtained are compared and discussed.

B. C. A.

The reciprocal salt pair $MgSO_4$-$Na_2(NO_3)_2$-H_2O. I. ALFRED BENRATH, H. PITZLER, N. ILIEFF, W. BEU, A. SCHLOEMER, J CLERMONT, S. KOJITSCH AND H. BENRATH. Aachen Tech. Hochschule. *Z. anorg. allgem. Chem.* **170**, 257-87(1928).—The isotherms of the system $MgSO_4$-$Na_2(NO_3)_2$-H_2O are studied at 15°, 25°, 50° and 97°. Equil. is insured by allowing solns at 15° to stand for 14 days, solns. at higher temp. a somewhat shorter time. Values of d are detd. by means of a weighing pipet. Space models of each isotherm are constructed and in each case the 4 binary systems are detd in detail: $MgSO_4$-$Mg(NO_3)_2$-H_2O, $Mg(NO_3)_2$-$Na_2(NO_3)_2$-H_2O, $Na_2(NO_3)_2$-Na_2SO_4-H_2O, Na_2SO_4-$MgSO_4$-H_2O. At 15°, the only double salt which occurs is *darapskite*, Na_2SO_4.$NaNO_3$.H_2O. Na_2SO_4 is present as Glauber's salt, $MgSO_4$ as bitter salt, $Mg(NO_3)_2$ as hexahydrate and $Na_2(NO_3)_2$ in the H_2O-free form. The sulfates take up the greatest space in the diagram. At 25° both darapskite and *astrakanite*, $MgSO_4$.Na_2SO_4.$4H_2O$, are present. At 50° darapskite has nearly vanished, the zone of astrakanite has enormously increased and Glauber's salt and bitter salt have been replaced by *thenardite* (Na_2SO_4) and $MgSO_4$.$6H_2O$. At 97° the $Mg(NO_3)_2$ field has vanished. In the place of astrakanite the H_2O-free double salts $MgSO_4$.Na_2SO_4 and $MgSO_4$.$3Na_2SO_4$ (*vanthoffite*) are found. $MgSO_4$ and its double salts occupy the greater part of the space model. The nitrate and Na_2SO_4 fields are very small.

H. STOERTZ

The equilibrium of the system: barium carbide, barium oxide, carbon and carbon monoxide. M. DEKAY THOMPSON. *Trans. Am. Elektrochem. Soc.* **54** (preprint), 15 pp.(1928).—The equil pressure of the reaction $BaO + 3C \rightleftharpoons BaC_2 + CO$ were measured in an Arsem vacuum furnace. This system has 3 degrees of freedom; in other words, the solid substances form a solid soln. Consistent results were obtained at 1141° and 1295°. However, at 1375° dissocn. of the carbide, or some other disturbing cause, prevented making a satisfactory series of measurements.

C. G. F.

The equilibrium in the system: magnesium oxide–magnesium chloride–water at 25° and 50°, and the constitution of magnesia cements. TUTOMU MAEDA AND SIGERU YAMANE. *Bull. Inst Phys Chem. Research* (Tokyo) 7, 340–57(1928); abst. in *Abstracts from Rikwagaku-Kenkyu-jo Iho* 1, 31-2. (In Esperanto.) Cf. *C. A.* 20, 3222.—Largely a re-publication. Besides the expts. at 50°, preliminary expts. at 25° are described which indicate the same 3 solid phases ($MgO.H_2O$, $MgCl_2.6H_2O$, and $3MgO.MgCl_2.12H_2O$). Beside the 3 cases given for cement constitution in *C. A.* 20, 3222, a 4th special case is recognized in which there is no equil. The letters *a, b, c, x, y, z, s* and *t* in the previous abst. represent g. mols. AUSTIN M. PATTERSON

The iodide, iodine, tri-iodide equilibrium and the free energy of formation of silver iodide. GRINNELL JONES AND B. B. KAPLAN. *J. Am. Chem. Soc.* 50, 1845–64 (1928).—A critical survey of sources of error in previous work is given, and a modified potentiometer described which permits detns. to 0.02 mv. in a cell having a resistance of 1.6×10^6 ohms. The potentials of a no. of I concn. cells have been measured. The soly. of I in $N/3$ KI at 25° and 0° has been detd. The equil. const. $(I^- \times I_2)/I_3 = k$ has been found to be 0.00140 at 25° and 0.00072 at 0°, the const. decreasing in solns. concd. in I as if higher polyiodides were formed. This effect has been minimized in the detn. of the free energy of formation of AgI, the results obtained showing no variation with concn. between 0.01 *N* and 0.05 *N*, and give 15,802 cals at 25° and 15,680 cals. at 0°. The free-energy change per degree is 4.8, the heat of formation 14,354 cals. Uncertainty as to the entropy of I prevents a thorough test of the third law. W. T. R.

Equilibrium in the ternary system: CrO_3–SO_3–H_2O. A. V. RAKOVSKII AND D. N. TARASENKOV. Moscow Univ. *Z. anorg. allgem. Chem.* 174, 91–6(1928).—Equil. in the system Cr_2O_3-SO_3-H_2O was measured at 0°, 20°, 40°, 75° and 100° by detg. the soly. of CrO_3 in H_2SO_4. The soly curve passes through a min. corresponding to 57.76% SO_3 in the liquid phase. The system was studied for some distance into the metastable region, however. The results are expressed diagrammatically. The hydrate $SO_3.2H_2O$ formed mixed crystals with CrO_3. This compd. decompd. in air of more than 1.7% humidity with a definite color change from yellow to red. R. L. DODGE

Osmosis of ternary liquids. III. Experimental part. F. A. H. SCHREINEMAKERS AND B. C. VAN BALEN WALTER. *Verslag Akad. Wetenschappen Amsterdam* 37, 435–43(1928); cf. *C. A.* 22, 1885.—In parts I and II, only the apparent osmosis had been considered. In this paper, the real paths of the components through the membrane are considered. A. L. HENNE

Note on temperature measurement between 20° and 70° absolute. F. HENNING. *Naturwissenschaften* 16, 617(1928).—Between $T = 20°$ and 90° abs. the Kamerlingh Onnes and Tuyn table for a Pt resistance thermometer accurate to 0.1° can be represented by $W' - W = (273 - T)[A - \{(B/(T + 10)\}]$ with *A* and *B* empirically detd. from *W* measurements at the b. ps. of H_2 and O_2 (T = 20.42 and 90.23); *W* stands for R'_t/R'_0, the ratio of resistances. B. J. C. VAN DER HOEVEN

Thermoelectric measurement of temperatures above 1500° (tungsten-graphite couple). H. L. WATSON AND H. ABRAMS. *Trans. Am. Electrochem. Soc.* 54 (preprint), 12 pp.(1928).—After a brief discussion of the standard methods of temp. measurements from 1000° to 2000° an account is given of a W graphite thermocouple, including its construction, characteristics and application. This couple has been used, with suitable protection, to over 1700° in oxidizing atms. Repeated runs to 1850° have been made in the vacuum furnace, as well as short runs to about 2400° at 1 atm pressure in reducing atms. The elements when properly selected and treated are interchangeable within 5% and an expression has been obtained for the temp. e. m. f. relation over the useful range. Automatic recording and control of furnace temp. in ceramics and steel making have been made possible by use of this couple. C. G. F.

A note on the high-low inversion of quartz and the heat capacity of low quartz at 573°. R. E. GIBSON. Geophys. Lab., Carnegie Inst. of Washington. *J. Phys. Chem.* 32, 1206–10(1928).—Although quartz usually superheats or supercools before the high-low inversion takes place, it is possible to convert low quartz reversibly to high quartz at a temp. of 572.3 ± 0.2°. This conclusion is reached from a careful study of heating and cooling curves of a solid block of Brazilian quartz. Before a block of quartz inverts from the low to the high form it usually superheats so much that the temp. does not fall to the equil. temp. during the inversion. The drop in temp. is, however, fairly const. and together with the latent heat of inversion gives the apparent heat capacity of low quartz at 573° as 4 ± 1 cal. per g. per degree. R. E. G.

The influence of pressure in the high-low inversion of quartz. R. E. GIBSON. Geophys. Lab., Carnegie Inst. of Washington. *J. Phys. Chem.* 32, 1197–205(1928).—When quartz is subjected to a uniform hydrostatic pressure of *p* megabaryes, the temp.

of its high-low inversion is raised according to the following equation: $\Delta T = -0.3 + 2.1 \times 10^{-2}p + 8.6 \times 10^{-7}p^2$. This equation expresses the results of direct exptl. observations made between 0 and 3000 megabaryes. From the initial pressure coeff. and the instantaneous vol. change during the transformation it follows that the latent heat of inversion is 3.1 cal. per g. R. E. GIBSON

Thermal conductivities of oxygen and nitrogen. HAMAR GREGORY AND SYBIL MARSHALL. Imperial College. London, England. *Proc. Roy. Soc.* (London) **A118**, 594–607(1928).—G. and M. have verified that the cond. of air should lie between O and N and should be nearer the N. Weber and Todd have also verified this but Winkleman dissents. Two systems of main and compensator tubes in gaseous connection were used. The diam. of the tubing in the 2 systems was different, thus affording a check on the supposed point at which convection vanished. Identical results should be obtained if the app. were perfect but a max. discrepancy of 0.5% was found. In the tubes was stretched a fine Pt wire. The main and compensator wire were connected, each in series with a standard 1-ohm coil, to a Callender-Griffith bridge. Each standard resistance in series with a main wire was connected to potentiometer circuit and the temp. of the wires was kept const. The O_2 was prepd. from $KMnO_4$, passed through KOH soln. and then over KOH sticks and P_2O_5. The N_2 was prepd. from $NaNO_2$, $K_2Cr_2O_7$ and Na_2SO_4, the gas was passed through chromic acid towers, then through H_2SO_4 towers and then over Cu turnings at a red heat. The abs. thermal cond. of O_2 at 0° is 5.89×10^{-5} cal. cm.$^{-1}$ sec.$^{-1}$ deg.$^{-1}$ with a temp. coeff. of 0.00289. The corresponding values for N_2 being 5.80×10^{-5} cal. cm.$^{-1}$ sec.$^{-1}$ deg.$^{-1}$ and 0.00293. S. L. B. ETHERTON

The properties of certain metal hydrides. A. SIEVERTS AND A. GOTTA. Chem Inst., Jena. *Z. anorg. allgem. Chem.* **172**, 1–31(1928).—Ce, Pr and a La-rich alloy absorbed the following amts. of H_2 at room temp. and atm. pressure, resp.: 2.79, 2.84 and 2.76 atoms per atom of metal. The ds. of the metals were 6.734, 6.514, 6.687; of the hydrides, 5.55, 5.56, 5.83; the % loss in density on hydrogenation, 17.5, 14.6, 12.8. The *heats of soln.* of 1 g. of metal in 2 *N* HCl (except the La-rich alloy in *N* HCl) were 1229, 1240, 1201 cal. for the untreated metals and 1203, 1198, 1184 for the fused metals. The *heats of formation* of 1 g. of the hydrides were 405, 381, 385 cal. The heats of formation of the hydrides per mol. H_2 contained were 42,260; 39,520; 40,090 cal. These values are close to those for the hydrides of Ba, Sr and Li. The hydrides of the alkali and alkaline earth metals, however, are denser than the corresponding metals. In this respect Ti, Zr and V are similar to Ce, Pr and La. The similarity of these latter two groups extends to the gray to black color and metal-like nature of the resp. hydrides. DAVID DAVIDSON

A method of determining the absolute zero of temperature. J. R. COTTER. *Phil Mag.* [7], **6**, 318–20(1928).—C. suggests an expt. for measuring the quantities occurring in Clapeyron's equation and proposes to use them to measure the thermodynamic scale of temp. and to det. zero abs. GEORGE GLOCKLER

The theory of heats of fusion. N. RASHEOSKY. Westinghouse Research Lab. *Phys. Rev.* **29**, 220(1927).—By plotting the potential energy, ϕ, of an aggregation of atoms *vs.* the at. distance, δ, a curve is obtained having a min. at $\delta = \delta_0$ (δ_0 = space lattice const. at 0 abs.) and tending asymptotically to zero for $\delta = \alpha$. At these points $d\theta/d\delta = 0$. Between them, at some point δ_1, $d^2\phi/d^2\delta = 0$. As long as $\delta < \delta_1$ the deformation of the body causes a force to appear, which tends to restore the initial state, and which increases with increasing deformation. For $\delta > \delta_1$ the restoring force diminishes with increasing deformation. Hence there is no question even about an approx. behavior of the body as an elastic one. This leads to the assumption, that when by thermal agitation the space-lattice const. reaches the value δ_1, the body becomes liquid. The amt. of work necessary to increase δ from δ_0 to δ_1 is thus interpreted as the total heat of fusion. By using for ϕ the expression $\phi = A/\delta^3 - B/\delta^n$ and calcg. A, B and n from the compressibility and thermoelastic consts. of Gruneisen, the heats of fusion of 7 metals were calcd. and found in fair agreement with the exptl. results. R. L. H.

The specific heat of solid substances. v. JÜPTNER. *Feuerungstech.* **16**, 97–102 (1928).—In the formulas for the sp. heats of solids by Einstein, Nernst, Debye and the author appears a quantity $\beta\nu$, which is the product of the natural frequency of the atom by a universal const. This paper discusses its variations with temp., as detd by applying the formulas to exptl. data. Though the formulas are based on the sp heats at const. vol., those at const. pressure may be used for this purpose without much error. As a rule, $\beta\nu$ increases with temp. to a max. and then falls off. The abs. temp at which this max. occurs is a much larger fraction of the m. p. with cubic and hexagonal lattices than with others. Where elements have several crystal forms $\beta\nu$ is largest

when the at. distance is greatest. For elements of the same lattice type, the temp. at which $\beta\nu$ attains half its max. value falls off with increasing at. wt. E. W. T.

The specific heats at low temperatures of manganous oxide, manganous-manganic oxide and manganese dioxide. RUSSELL W. MILLAR. *J. Am. Chem. Soc.* **50**, 1875–83 (1928).—By the method originated in Nernst's laboratory these specific heats have been measured from 70° to 300° K. With the aid of the third law of thermodynamics and the data of previous investigations values are computed which are summarized as follows:

Substance	Mn	O_2	MnO	Mn_3O_4	MnO_2
S_{298}	7.3	49.2	14.92	35.73	13.93

Reaction	ΔH	ΔS	ΔF
$Mn + 1/2O_2$	− 90,900	−17.0	− 85,830
$3Mn + 2O_2$	−328,000	−84.6	−302,800
$Mn + O_2$	−125,300	−42.6	−112,600

Theory of the specific heat of methane. JAKOB KUNZ. Univ. of Ill. *Phys. Rev.* **29**, 220(1927).—The results of Dennison's analysis of the oscillations of CH_4, based on the infra-red absorption bands, and the quantum theory of radiation are used for the theoretical detn. of the sp. heat of CH_4. The theoretical values are a little higher than the exptl. (plotted *vs.* temp.) R. L. HERSHEY

Thermodynamic aspects of the constitution of compounds of tervalent and multivalent elements. GOTTFRIED BECK. Univ. Zurich. *Z. anorg. allgem. Chem.* **174**, 31–41(1928).—The application of the logarithmic contraction equation $kQ = 546(\log V_a - \log V_c)$ where Q = heat of formation, to compds. of tervalent and multivalent elements is studied, particularly the role of the reaction const. k as a function of electron configuration and its significance for the quantum mech. explanation of certain chem. processes. Values of k are given in a table for the halides, oxides, sulfides and sulfates of various metals. The normal value for the halides is found to vary from 0.57 to 0.60, and with this value the most stable complex formation is of the type $Me'_3Z^{III}X_6$, having the coördination no. of 6. The only exception to this is VCl_3, which forms the compd. $KVCl_4$. The higher values of k obtained for the Bi halides and $FeCl_3$ (0.8 − 0.9) indicate a different mol. structure, the normal type of complex here being $Me'_2Z^{III}X_5$. For Sb and Bi fluorides the normal form is $Me'Z^{III}F_4$. The extreme values of k obtained for the iodides of Sb and As (1.61 and 3.08) indicate that here with a corresponding contraction a smaller quantity of energy is liberated. This is explained as due to the rotation of the valence electrons on a widely extended orbit with a low energy level. For the rare earth halides values of k are about 0.44, indicating a more closely confined orbit for the valence electrons. The oxides in general agree very closely with the chlorides. For the sulfates the group Al, Fe, Cr, In with k about 0.30 form alums; the group Tl, Sb, Bi, Mn with k 0.55 to 0.62 are in general quantitatively hydrolyzed; the rare earths with k about 0.12 probably have a different ion lattice. The relation between electron configuration, chem. behavior and values obtained for k is discussed for many of these compds. It is shown that the sulfates of Th and U on the one hand and Zr and Ce on the other hand are thermodynamically equiv. and therefore show similar complex salts. Density detns. and measurement of the heat of formation of some of these compds. are made. In the case of the sulfates the reaction is between oxide and SO_3 and in the case of the halide between metal and halogen. Q in kg.-cals. is given as follows: $Tl_2(SO_4)_3$ 105, $Mn_2(SO_4)_3$ 85, $Sb_2(SO_4)_3$ 79.1, $Bi_2(SO_4)_3$ 102, $Sn(SO_4)_2$ 46.5, $Zn(SO_4)_2$ 104, $Ce(SO_4)_2$ 103.5, $Th(SO_4)_2$ 115.5, $U(SO_4)_2$ 78, $UO_2(SO_4)_2$ 50, $ZrCl_4$ 142, $TeBr_4$ 57, LaF_3 402. H. STOERTZ

Entropy of dilute solutions. A. LANDÉ. *Z. anorg. allgem. Chem.* **171**, 143–5 (1928).—Theoretical. L. gives a new derivation of Planck's formula. H. S. v. K.

Tribo-electricity and friction. II. Glass and solid elements. P. E. SHAW AND C. S. JEX. *Proc. Roy. Soc.* (London) **A118**, 97–108(1928); cf. *Ibid* **A111**, 339.—By means of an arrangement designed to give const. conditions of pressure and surface, measurements have been made of the sign and amt. of charge acquired when glass rods and various solid elements are rubbed together. The elements tested were of a high degree of purity, special attention being paid to surface cleanliness. The glass cleaned by boiling in chromic or nitric acid, followed by exhaustive treatment with boiling water. The following elements never, with any type of glass surface tried, give neg. charge: C, Cd, Fe, Pb, Bi, Ag, Cu, Au, Pt, Mg, W. The elements Zn, Sn, Al,

Sb, Ni, Co, Se, Te, As, Cr, Th and S acquire an ultimate neg. charge. The initial pos. charge shown is attributed to the slight acid effect residual on the glass. In the few cases tested, rubbing in a vacuum gives the same result as in the open air. Little difference in degree is found, and none in sign, between the behavior of soda and lead glass. Evidence is given of the predominating influence on the charging of residual acid, alkali or water films on the glass. Hg, tested in a vacuum by a special method, shows pos. charges, but becomes neg. if air is introduced. Various theories of frictional electricity are discussed, and an attempt is made to apportion to each recognized source of charge its own weight in the various expts. III. **Solid elements and textiles.** *Ibid* 108–13.—The textiles tested were specially purified silk, cotton and filter-paper. The arrangement of the different elements, according as they charge textiles and glass, is found to correspond closely with their chem. qualities. It is impossible to devise a simple tribo-elec. series of one column to include all solids, for it is found that of 3 solids (A, B, C) A may be pos. to B, B to C, and yet C be positive to A. Anomalies are found with the strongly electro-pos. metals Al, Mg, Cr, Ni, Co, Zn and Sn, which appear in 2 places in the tribo-electric series. B. C. A.

The supraconductive state of gray tin. W. J de Haas, G. J. Sizoo and J. Voogd. *Proc. Acad. Sci. Amsterdam* **31**, 350–2(1928).—See *C. A.* **22**, 1880. E. H.

Contact electricity, thermoelectricity and cohesion pressure. R. von Dallwitz-Wegner. *Z. Elektrochem.* **34**, 42–9(1928).—Values of the cohesion pressure, K, of various substances at 0° and 100° are calculated from the relation, $K = 84.1\, d\, [(1 + at)/a]/M$, where d = density, M = mol. wt., t = temp. and a = coeff. of cubical expansion. For solids the values of K range from 13×10^6 for diamond to 56.5×10^3 for Pb at 0°, the sequence of the various substances corresponding with the order of hardness. For Hg at 0°, $K = 31 \times 10^3$. The relation of the cohesion pressure to contact electricity and thermo-electricity is discussed, and an equation is developed whereby the e. m. f. of a thermo-element with a temp. difference of 100° between the hot and cold junctions can be calcd. from the cohesion pressure data. For a Pt-Ag element satisfactory agreement is obtained with the observed value, but for many thermo-elements there are notable discrepancies. These discrepancies are attributed to the fact that small quantities of impurities in the metals can have a large effect on the e. m. f. and on K, so that agreement can be expected only if K is detd. for the particular samples of metal used in the thermo-element. B. C. A.

Valency of chromium in its deposition from aqueous solutions of chromic acid. E. Liebreich. *Z. Elektrochem.* **34**, 41–2(1928).—Whereas the data obtained by Shcherbakov and Essin (*C. A.* **21**, 3163) for current efficiencies in the electrolysis of chromic acid solns. contg. a high concn. of H_2SO_4 correspond with the formation of Cr by discharge of chromic ions, the data for solns. weaker in H_2SO_4 are in better agreement with the view that the metal is formed by discharge of chromous ions. B. C. A.

Cathodic overvoltage. E. Liebreich and W. Wiederholt. *Z. Elektrochem.* **34**, 28–41(1928).—In continuation of previous work (*C. A.* **18**, 3525; **20**, 141), the course of current-potential curves has been detd. for the cathodic and anodic polarization of electrodes of Cu, Ag, Au, Pt, Pd, graphite and amorphous C in 0.02 N H_2SO_4 and for Cu and Ag electrodes in 0.02 N NaOH. With increasing cathodic polarization, all the metals exhibit an "activation period" before H evolution begins. During this period, the metal becomes coated with a thin film of hydroxide or basic salt which hinders the evolution of H, either mechanically or by consuming it in reduction processes. The H overvoltage of the metals is regarded as being essentially detd. by this film formation. The formation of the film itself is attributed to the reaction of the metal with the OH ions liberated in its immediate neighborhood by the initial discharge of H ions to form H which is occluded in or adsorbed by the metal. Amorphous C exhibits no activation period and graphite scarcely any. In these cases the H overvoltage is attributed to the formation of gaseous hydrocarbons and the occlusion of these gases and of H in the electrode. It is suggested that the H overvoltage of metals is intimately connected with their capacity for becoming coated with a more or less adherent film of the type which is associated with passivity phenomena. B. C. A.

Determination of dipolar moments from critical values of physical properties. Ya K. Suirkin. Polytechnic Inst., Ivanova Vosnessensk. *Z. anorg. allgem. Chem.* **174**, 47–56(1928).—The following expression for elec. dipolar moments is derived: $m = 1.66 \times 10^{-20}\, T_{cr}/\sqrt{P_{cr}}$, in which T is the crit. temp. and P the crit. pressure. By this formula, m is calcd. for 79 different substances, some of the results being as follows: $m.10^{11}$ being given: Cl_2 0.79, O_2 0.36, N_2 0.36, O_3 0.54, CO 0.38, CO_2 0.59, CS_2 1.06, SO_2 0.82, SO_3 0.89, NO 0.37, NO_2 0.72, HCl 0.60, H_2O 0.73, H_2S 0.66, NH_3 0.64,

PH, 0.67, CH_3Cl 0.85, $CHCl_3$ 1.21, C_2H_5Cl 1.03, C_3H_7Cl 1.24, C_6H_5Cl 1.57, $(C_2H_5)_2O$ 1.30, CH_3OH 0.96, C_2H_5OH 1.08, C_3H_7OH 1.26, $C_6H_5CH_3$ 1.53, C_2H_4 0.65, $C_2H_5NH_2$ 1.02, $C_3H_7NH_2$ 1.21, $(CH_3)_3N$ 1.08, CH_3COOH 1.05, C_3H_7COOH 1.41. In a homologous series of org. compds., *m* increases in a regular manner as each CH_2 group is added, the amt. of increase becoming smaller as the no. of CH_2 groups in the mol. rises. Beginning with 0.19 the increase falls to 0.11 as CH_2 groups are added to the series commencing with CH_3COOH. Additive properties of the dipolar moments are indicated in reactions where the initial as well as the final substances are typically dipolar, the sum of the moments on each side of the equation being approx. equal. H. Stoertz

The electrolytic behavior of thin films. I. Hydrogen. F. P. Bowden and E. K. Rideal. *Proc. Roy. Soc.* (London) **A120**, 59–80(1928).—The beginning of a series of expts. to find out how the potential of an electrode varies as the first few layers of atoms are deposited. H is studied first. The potential changes were measured to 0.01 sec. by recording the fluctuations of a strong galvanometer on a moving photographic film. O_2 had to be carefully excluded as its presence affects the apparent rate of growth and decay of the active H surface markedly. B. and R. find the following equation valid, $-E = \beta\Gamma + \text{const.}$, where E is the electrode potential, Γ is the true surface concn. of active H on the cathode surface, and β is a const., the same for all metals forming the cathode. The cathodic potential for all metals is raised 100 milli-v. by 0.0003 of an at. layer of H. The rate of decay of the active surface is give by the equation $-d\Gamma/dt = k_1 e^{-k_2E}$. B. and R. think the potential due to the presence of an elec. doublet (elec. moment, $\mu = 7.2 \times 10^{-18}$ e. s. u.) composed of a proton and a negative H ion sepd. by the distance 1.5×10^{-8} cm. **II. The areas of catalytically active surfaces.** *Ibid* 80–9.—The catalytic activity and the surface area under different conditions of annealing, rolling, activation and electroplating for C, Ag, Pt and Ni are studied. The area of Pt black may be 2000 times its apparent area, that of sand-papered metal 10 times, and that of Ni activated by alternate oxidation and reduction 5 times. Rolling reduces the accessible area. The sp. activity for the deposition of H differs widely among the metals, but it is not affected much by chem. or thermal treatment. Sand papering or rolling increases the activity, which gradually diminishes with aging of the cathode. Malcolm Dole

Theory of cell with liquid junction. Paul B. Taylor. Univ. of Penn. *Phys. Rev.* **29**, 369(1927).—In deriving an integral for the e. m. f. of a cell with liquid junction in terms of transference nos and mol. free energies, the transference nos. are made to depend on solving a set of differential equations for the interdiffusion of two electrolytes. Ionic mobilities and mol. free energies are involved in the equations. Ionic free energies are not involved. L. D. R.

An electronic theory of passivity. William D. Lansing. Univ. of Ill. *Phys. Rev.* **29**, 216–7(1927).—Under normal conditions the electrons of Fe are probably distributed among the energy levels as 2, 8, 14, 2. Under strong oxidizing conditions this may become 2, 8, 8, 8, a structure analogous to Kr, and thus becomes passive and non-magnetic. Thin films of Fe produced by a method of cathode sputtering were passive. The magnetic measurements are not complete. The electrode potential of ordinary Fe in 0.5 molal $FeSO_4$ was +0.365 with respect to the H electrode; the corresponding value for passive Fe was −0.508 Thermodynamically, passive Fe is the more stable, with a free-energy change of 35,700 cal. The electrode potential of sputtered Fe in this soln. ranged from 0.035 v. to −0.065 v. becoming more noble with time. This is explained by the supposition that the film is still too thick to be passive and non-magnetic all the way through. R. L. H.

The electronic theory of valency. VI. The molecular structure of strong and weak electrolytes (*b*) reversible ionization. T. Martin Lowry. *Phil. Mag.* [7], **6**, 50–63(1928).—See *C. A.* **22**, 724. George Glockler

The dielectric polarization of liquids. III. The polarization of the isomers of heptane. C. P. Smyth and W. N. Stoops. *J. Am. Chem. Soc.* **50**, 1883–90(1928); cf. *C. A.* **22**, 3572.—The dielec. consts., ds., ns, dispersions and viscosities of the isomers of heptane and 2,2,4-trimethylpentane have been measured. From the ds. and dielec. consts. over the entire range where these are liquid no elec. moment is found. Conclusion: The atoms in a satd. hydrocarbon mol. may be joined together in every possible configuration without giving rise to any measurable lack of elec. symmetry, although very small differences in the rigidity of binding of the electrons are detected. W. T. Richards

Principal susceptibilities of manganese ammonium sulfate crystals at low temperatures. L. C. Jackson and W. J. de Haas. *Proc. Acad. Sci. Amsterdam* **31**, 346–9(1928).—See *C. A.* **22**, 1528. E. H.

Magnetic susceptibility of single-crystal elements. C. Nusbaum. Case School of Applied Sci. *Phys. Rev.* **29**, 370(1927).—By means of a modified Terry torsion balance the magnetic susceptibility of Te has been detd. Single crystals of Cd, Bi, Sb, Sn and Zn are being similarly studied. L. D. R.

Magnetic susceptibility of single-crystal metals. C. Nusbaum. Case School of Applied Sci. *Phys. Rev.* **29**, 905(1927).—The mass susceptibility for Bi has been found to be 1.13 $\times$ 16^{-6} parallel to the principal axis and 1.32 $\times$ 10^{-6} dyne cm. in a perpendicular direction. Resp. values for Sb are 0.497 $\times$ 10^{-6} and 1.38 $\times$ 10^{-6}. L. D. R.

Magnetic studies on salts, with particular reference to those with complex ions. Lars A. Welo. Rockefeller Inst. for Medical Research. *Phil. Mag.* [7], **6**, 481–509 (1928).—The salts, 124 in number, studied are of the following groups: Polynuclear salts of Fe and Cr having very large negative values of Θ in the Curie-Weiss law $K_\alpha (T - \Theta) = C$. T = abs. temp. K_α, Θ, C are const. Fe salts having irregular and variable moments within the observed range of temps. Miscellaneous salts of Fe and Cr of normal ionic moment and with relatively small values of Θ in the Curie-Weiss law. Coordination compds. of Cr and Co. Ferricyanide, pentacyano derivatives and Prussian blues. Salts showing an anomalous temp. variation of the susceptibilities. Diamagnetic and near diamagnetic salts of some transition elements. George Glockler

Magnetic susceptibility of rare-earth metals. E. H. Williams. Univ. of Ill. *Phys. Rev.* **29**, 218(1927).—The magnetic susceptibilities of Ce, La, Pr and Yt have been detd. In each case the value of the susceptibility depends upon the intensity of the magnetic field, decreasing as the field is increased from 10 to 4000 gausses. In this respect the magnetic susceptibility of the rare earth metals resembles the behavior of the permeability of Fe. Because of the low value of the susceptibilities, 20 $\times$ 15^{-6} to 50 $\times$ 10^{-6} dyne cm. per g., for the fields used, it is impossible with the methods available to fill in the gap for fields between 10 gausses and zero. This gap is the most interesting part of the curve. R. L. Hershey

Subjective influences in colorimetric work, and their elimination. J. Eisenbrand. *Pharm. Ztg.* **73**, 909(1928).—A discussion of certain characteristic cases with suggestions for eliminating possible disturbing factors by means of suitable light filters. W. O. E.

Selenium cells as colorimeters. A. Mickwitz. *Z. anorg. allgem. Chem.* **171**, 285–311 (1928).—In order to study the absorption of light by a soln. the effect of the transmitted light on the resistance of a Se cell, measured by the current passing when a const. p. d. is applied, may be compared with the effect obtained by using as absorbent a layer of water of the same thickness, and the same source of light. In order to eliminate the effect of variations in the properties of the cell with the time and also hysteresis effects in the resistance, the cell is exposed to the light transmitted by the water and the light transmitted by the soln. for alternate periods of 20 sec. each, each period of illumination being sepd. from the following period by 40 sec. of darkness, and this is continued until the current corresponding with each kind of light becomes constant. The absorption by the soln. is then expressed numerically by the ratio x of the quantity (current passing through the cell when illuminated by the light transmitted by the soln.—current passing in darkness) to the corresponding quantity for the water. Absorption curves constructed in this way for solns. of $CuSO_4$ and $Cu(NO_3)_2$ may be used for the colorimetric detn. of these salts, the mean error with the sulfate being $\pm$ 1.5%. As the value of x is affected considerably by variations in the p. d. applied to the cell, this should be kept const. for all the measurements. Iron may be detd. colorimetrically in the form of colloidal FeS, the oxidation of which with consequent change of color, is delayed by addn. of Na_2SO_3, the mean error is $\pm$ 2.5%. Expts. of this kind show that a satd. soln. of FeS at the ordinary temp. contains 0.0028 g. of iron per l. B. C. A.

Reproducible liquid filters for the determination of the color temperatures of incandescent lamps. Raymond Davis and K. S. Gibson. Bur. of Standards. *Phys. Rev.* **29**, 916(1927).—A series of filters, reproducible from specification, has been worked out whereby any Planckian energy distribution between 2300° and 4000° K. may be converted to the color of mean Washington sunlight, thus permitting exact calibration of a lamp by photometric measurements. The specifications of the filter solns. are not given. W. W. Stifler

Hydrogen. VII. Density, refractivity and absorption of light of concentrated aqueous solutions of hydrogen halides. G. F. Hüttig and H. Kükenthal. *Z. Elektrochem.* **34**, 14–8(1928); cf. *C. A.* **22**, 360.—In continuation of similar work on solns. of Li halides (*C. A.* **20**, 699), ds. and refractivities of solns. of HCl and HBr at various concns. have been detd. and coeffs. of extinction for HCl solns. measured in

the region λ2300–2800.* Further data for the ds., mol. contractions and refractivities of solns. of Li halides are also recorded. B. C. A.

Electrical and luminous effects produced by rolling mercury on glass in a vacuum. M. DUFFIEUX. *J. phys. radium* [vi], **9**, 61–70(1928).—The effects produced by rolling Hg in an evacuated flask have been studied. A current is found to be set up between the Hg as pos. pole and the glass as neg. pole. At temps. below 100° the discharge caused by this current emits the arc spectrum of Hg, but above 100° a phosphorescent vapor above the liquid emits the continuous spectrum of Hg. The mechanism of the electrification is discussed. It is found that the elec. layer which attracts the liquid is on the glass. B. C. A.

Disappearance and reversal of the Kerr effect. C. V. RAMAN AND S. C. SIRKAR. *Nature* **121**, 794(1928).—Observations on the Kerr effect with octyl alc. confirm Raman and Krishnan's theory of elec. birefringence in liquids (cf. *C. A.* **21**, 2419). B. C. A.

Polarization of λ 2537 of mercury. H. F. OLSON. *Phys. Rev.* **29**, 207(1927).—1 S-2p_2 of Hg excited by plane polarized light shows 79% polarization both in the absence of any magnetic field and in the presence of a field parallel to the elec. vector in agreement with the results of Keussler. That such a field should produce no change in polarization is in accord with Heisenberg's extension of the principle of spectroscopic stability. That the polarization is not complete might be interpreted as due to collisions but more probably is due to the fact that in very weak fields some of the fine components of 2537 have not the same Zeeman effect as in strong fields. The polarization with other relative orientations of field and light vector and the variation of polarization with field intensity in weak fields may be successfully interpreted by means of a semi-classical model, with proper relative intensities parallel and perpendicular to the light vector, rotating after excitation with an angular velocity $^1/_2\ g\ (e/m)\ (H/c)$ and emitting a damped wave. From curves connecting depolarization, rotation of max. of polarization, etc., with field intensity K has been found to be $1.02(\pm.02)10^7$ sec.$^{-1}$. R. L. H.

Statistical series of the Charlier *A* type and Boltzmann' equation. U. WEGNER. *Z. Physik* **45**, 539–47(1927).—Mathematical. H. G.

Ethylene glycol as an atmometer reagent to measure the evaporating environment at temperatures below freezing. A. L. BAKKE AND J. M. AIKMAN. Iowa State College. *Science* **68**, 162–4(1928).—Since app. for measuring the humidity of the atm., which depends on the evapn. of H_2O, is not suitable below the f. p. when H_2O itself is used, the authors suggest the substitution of a soln. of ethylene glycol of known concn., which may be detd. from the sp. gr. A 20% soln. is suitable for temps. down to 15° F. A chart is presented giving the correction factor, which is worked out by detn. of the relative rates of evapn. of the soln. and pure water at an unstated temp. Specifically, the atmometer of the standardized cylindrical type provided with a Livingston-Thone valve was used in these expts. The actual loss in wt. from a soln. multiplied by the proper correction factor then gives the wt. of pure H_2O which would have been evapd. under the same conditions. A. W. KENNEY

3—SUBATOMIC PHENOMENA AND RADIOCHEMISTRY

S. C. LIND

Metastable neon and argon. RICHARD RUDY. Research Lab. Nela Park. *Phys. Rev.* **29**, 359-60(1927).—Absorption of 6402 increased with lowering of pressure from 8 mm. downward and beyond the min. discharge potential. The volt-ampere characteristic was not changed by this absorption. Strong absorption was found in the negative glow. L. D. R.

Explanation of the long life of metastable atoms. G. BREIT. Carnegie Inst. of Wash. *Phys. Rev.* **29**, 361(1927).—Schrödinger's idea of radiation if $q(nm) = 0$ is first given. By estg. the life of an atom on the basis that radiation may exist in $q(nm) = 0$ corresponding to a coil aerial in radio for which the doublet also vanishes, it is found to be about a sec. L. D. R.

Determination of e/m. F. H. LORING. *Chem. News* **136**, 145-7, 161-5(1928).—The value selected from the work of European physicists is $e/m_0 = 1.7674 \times 10^7$ in e. m. c. g. s units. American physicists, according to L.'s method of averaging, find 1.7660×10^7. The grand av accepted by L. is 1.767×10^7. W. T. RICHARDS

Wave mechanics of atomic lattices. M. J. O. STRUTT. *Ann. Physik* **86**, 319-24 (1928).—The motion of electrons in 1-, 2- and 3-dimensional cryst. lattices has been considered mathematically from the standpoint of wave mechanics. A. J. KING

King's classical theory of atomic structure. BORIS PODOLSKY. Calif. Inst. Tech. *Phys. Rev.* **29**, 750(1927).—In his paper, "A Classical Theory of Atomic Structure and Radiation" (Mercury Press, Montreal), King assumes all electrons spinning with the same angular velocity. The electron in motion suffers a Lorentz-Fitzgerald contraction which is supposed to cause precession. He obtains a picture of the quantum mechanism by assuming the frequency of precession to equal the frequency of incident radiation in the case of photoelec. phenomena and to an integral multiple of the orbital frequency in the case of radiation P shows the electron could not have a precession, that it could not have a precession and absorb energy without changing the frequency of precession and that as the precession of the electron, due to causes other than those discussed by K., has found its place in explaining normal doublets and triplets, *i. e.*, small changes in frequency and not the whole effect, K.'s picture is undesirable. S. L. B. ETHERTON

Atomic mechanics. ALBERTO E. SAGASTUME BERRA AND RAFAEL GRINFELD. *Anales soc. cient. Argentina* **105**, 11-42(1928).—From the principle of d'Alembert, *i. e.*, "in the movement of a system, the forces applied at each point and the forces of inertia are in equil at each instant," the general results of Lagrange, Hamilton and Jacobi for the motion of a system are then derived in 56 equations. There follows a theorem of Larmor which may be stated and proved. Thence, with the help of quantum hypotheses, the normal Zeeman effect may be explained. Finally the method of Lagrange and Jacobi is applied to the movement of an electron subject to the action of an elec. nucleus and under the influence of an elec. field. S. L. B. ETHERTON

• **Wave mechanics of an atom with a non-coulomb central field. III. Term values and intensities in series in optical spectra.** D. R. HARTREE. Christ College. *Proc. Cambridge Phil. Soc.* **24**, Pt. 3, 426-37(1928).—Continuing the method of *C. A.* **22**, 1269, an expansion valid near the origin is found for the wave soln. of the wave equation in a Coulomb field for terms of non-integral quantum no. n. This allows a calcn of the quantum defect. The soln is of the form $G \cos \pi n + H \sin \pi n$, where for a given radius G and H are even functions of $1/n$. The extended Ritz formula follows. The law $I/\nu^4 \alpha 1/n^3$ for the variation of intensity in a series with effective quantum no. of the variable term is also derived from this result. F. R. BICHOWSKY

The classical reasonableness of the quantum theory and simple operative solutions of Schrödinger's equation. A. PRESS. *Phil. Mag.* [7], **6**, 33-49(1928).—Mathematical. GEORGE GLOCKLER

Heisenberg's indetermination principle. E. H. KENNARD. *Phys. Rev.* (ii) **31**, 344-8(1928).—The principle is applied to cases where the position and velocity of an electron are observed by allowing it to pass through shutters opened momentarily at known times B. C. A.

Physicochemical considerations in astrophysics. W. NERNST. *J. Franklin Inst.* **206**, 135-42(1928).—The large amts. of energy radiated by the sun may be due to the decompn. of radioactive elements of higher at. wt. than U. G. CALINGAERT

A suggested method for extending microscopic resolution into the ultra-microscopic region. E. H. SYNGE. *Phil. Mag.* [7], **6**, 356-62(1928).—A biological section ground

over a small surface to a plane (true to 10^{-6} cm.) moves over an aperture (diam. 10^{-6} cm.) illuminated from below. The light intensity is varied because of the different opacities of various sections of the specimen. A photoelec. cell is illuminated by the small light beam and a picture is produced as in telephotography. GEORGE GLOCKLER

Recent progress in the investigation of the elements and isotopes. OTTO HAHN. *Z. angew. Chem.* **41**, 516–23(1928). E. H.

The magnetic susceptibilities of electronic isomers. S. S. BHATNAGAR AND R. N. MATHUR. *Phil. Mag.* [7], **6**, 217–23(1928).—The const. *K* contained in the expression for diamagnetic susceptibility (cf. *C. A.* **22**, 2105) increases with the no. of atoms in the mol. It is const. for isomeric mols. For groups of isomers having the same no. of atoms in the mol., the values of *K* increase with the at. nos. of the groups. G. G.

The structure of matter. I. Hydrogen and oxygen. OTTO REINMUTH. *J. Chem. Education* **5**, 1152–63(1928).—Review. E. H.

The building stones of the atomic nuclei. STEFAN MEYER. Inst. Radiumforschung, Wien. *Scientia* **44**, 89–98(1928).—A review of the established facts regarding atomic nuclei. MARIE FARNSWORTH

System of structure for atomic nuclei. WARREN W. NICHOLAS. Cornell Univ. *Phys. Rev.* **29**, 612–3.—With the proton inside the electron (neutron structure) the "packing" effect may be explained. The evolution of light elements was from complex to simple, nuclei losing units smaller than the α-particle. With the protons and neutrons on alternate cubic corners in a cubic lattice, features are shown possessed by known nuclear series. A structure for the nucleus of S 32 is proposed which accounts for known isotopes from S 32 to He 4. S. L. B. ETHERTON

A measurement of radiation at about 5μ. KING E. GOULD. *J. Optical Soc. Am.* **17**, 198–206(1928). E. H.

Experiments on highly penetrating radiations from the earth. L. N. BOGOIAVLENSKY AND A. H. LOMAKIN. U. S. Bur. of Mines, *Information Circ.* No. **6072**, 1–13 (1928).—A contour map of the region of Pyatygorsk in the Caucasus showing the radioactivity of various points is drawn. By using Pb screens the hardness of the rays is detd. In several places near the surface the radium content of the deposit is 5×10^{-10} g per g. The radiations have been found to be quite const. The upper layer has little influence on penetrating radiation. L. D. R.

The amount of radon in the atmosphere according to measurements during airplane flights. A. WIGAND AND F. WENK. *Ann. Physik* **86**, 657–86(1928).—The purpose of the research was to answer the question of the vertical distribution of Rn in the atm. and its origin by direct measurement of the Rn content on airplane flights. After expts. with C adsorption, the method of condensing Rn with liquid O_2 was found to be the best adapted. The app. permitted 3 measurements of 3–7 min. duration for each flight. For 5 flights up to a height of 3800 m., the value found showed in general a strong decrease in Rn content with increasing height, decreasing to a very small value. The change of the Rn content with height was detd. by the origin and previous history of the air in the various layers. The measurements demonstrate the sole origin of the Rn of the atm. from the surface of the earth and show that the vertical distribution results only from the interchange of air. MARIE FARNSWORTH

Radiometric exploration of oil deposits. L. N. BOGOIAVLENSKY. U. S. Bur. of Mines, *Information Circ.* No. **6072**, 13–8(1928).—Penetrating radiation changes sharply between places a few m. apart. Measurements continued over a period of 3 years showed no variation in intensity at the various points. Intensity depends on concn. of radioactive elements in the earth's core. Oil possesses a high absorbing power for radioactivity. The colloidal materials underlying oil beds are richer in radium on account of absorbing power of colloids. L. D. R.

Some measurements of the radioactivity of the gases and water of the Ukhta oil-bearing region and of medicinal mud and brine from the salt lake of the Tinakee Station. A. CHEREPENIKOV. U. S. Bur. of Mines, *Information Circ.* No. **6072**, 18–20(1928).—Radioactivity was found in the gas from the Government's "crevice" N° on the Ukhta River. L. D. R.

Supplementary information on radioactive substances and methods for determining their location. F. W. LEE. U. S. Bur. of Mines, *Information Circ.* No. **6072**, 20–7(1928).—This article contains a discussion of the usual way of detg. radioactivity. L. D. R.

Multiple positively charged radioactive ions. LEONARD B. LOEB. *Science* **67**, 468–70(1928).—Recoil atoms from active deposits of Ra, Th and Ac appear to be multiply charged. The charge may be greater than three. Reasons supporting this affirmation and a method of investigating it are presented. W. T. RICHARDS

A suggested theory of electric conduction. W. H. McCrea. Trinity College, Cambridge. *Proc. Cambridge Phil. Soc.* **24**, Pt. 3, 438-44(1928).—According to the wave mechanics an electron in the neighborhood of two nuclei has a finite probability of shift from a quantum state belonging to one to a quantum state belonging to the other. This probability of shift is suggested as the mechanism of elec. conduction. The theory is not worked out completely, but a calcn. from the case of two nuclei gives conductivities of the right order. Qualitatively the theory looks promising.
F. R. Bichowsky

A new method of determination of the volume of one curie of radon. L. Wertenstein. Free University, Warsaw. *Phil. Mag.* [7], **6**, 17-33(1928).—The method described consists in measuring simultaneously the pressure and the coeff. of (external) friction of the gas. This coeff. is proportional in a highly rarefied, chem. pure gas to its pressure and to the square root of its mol. wt.; in a mixt. of gases to the sum of the products of the pressure and the sq. root of the mol. wt. of each constituent. The pressure was detd. by means of a calibrated Knudsen gage and the coeff. of friction by means of a quartz-fiber gage. The "damping," indicated by this gage as the inverse of the time during which the amplitude of the oscillations of the quartz fiber diminishes in a given ratio, is proportional to the coeff. of friction. CO_2 was the other gas used. The vol. of 1 curie of Rn is 6.39×10^{-4} cc. at normal pressure and temp. G. G.

A quartz-fiber electrometer. D. R. Barber. Univ. Coll. of the South-West of England, Exeter. *Phil. Mag.* [7], **6**, 458-65(1928).—A description is given of a double-plate electrometer employing a single suspended quartz fiber as the moving system. A method of rendering the quartz conducting by cathode sputtering of Ag is given, with a description of the technic developed in handling and mounting the fibers. The results of a direct calibration of the instrument are given, and compared with those obtained by other investigators using different types of electrometers. G. G.

The motion of a particle in a periodic field of force. S. L. Malurkar, Sidney Sussex College, and J. Hargreaves, Clare College, Cambridge. *Proc. Cambridge Phil. Soc.* **24**, Pt. 3, 447-50(1928).—The motion of a wave mechanics electron in a field of force which varies as the cosine of distance is as in the classical case excepting for terms corresponding to the Heisenberg uncertainty relation. F. R. Bichowsky

Wave equations of the electron. C. G. Darwin. *Proc. Roy. Soc.* (London) **A118**, 654-80(1928).—A mathematical paper. Dirac's work (*C. A.* **22**, 1535) is discussed by methods of differential equations instead of the noncommutative algebra used by D. The emission of radiation from an atom contg. D.'s "spinning electron" is discussed. The equations solved for the motion of an electron in a central field of force may be expressed in terms of spherical harmonics and lead to a doublet structure for the spectrum. The rule of combination is considered and the Zeeman effect is worked out. S. L. B. Etherton

Pseudo photographic effect of slow electrons. Jos. E. Henderson. Yale Univ. *Phys. Rev.* **29**, 360(1927).—With a magnetic spectrograph photographic plates subjected to a beam of slowly moving electrons showed a dark line at the position calcd. from the consts. of the app. 500-v. electrons discolored glass, quartz, calcite, Pt, Cu, Ni, Ag, Al, Zn, Pb and brass. The nature of the discoloration depends on the material.
L. D. R.

The electron in a gravitational field. J. M. Whittaker. Trinity College, Cambridge. *Proc. Cambridge Phil. Soc.* **24**, Pt. 3, 414-20(1928).—On the assumption of the ordinary gravitational equations the charge of the pos. nucleus of a H atom (wave mechanics model) should be $e(1 - \alpha/4a)$, where α and a are the relativity consts. This gives a displacement to the red of the H lines equal to that predicted on the relativity theory. If the gravitational theory of de Sitter is assumed, electrostatic potentials are everywhere modified as if the dielec. const. of space were $(1 - \mu r^2)^{-1}$. Einstein's theory gives the dielec. const. of space to be $(1 + \mu r^2)^{-1}$. F. R. B.

Transference numbers of ions in solid sodium chloride at high temperatures. T. E. Phipps and R. T. Leslie. Univ. of Illinois. *J. Am. Chem. Soc.* **50**, 2412-21 (1928).—Transference expts. were performed on NaCl at temps. varying from 410° to 655°, a reversible Na anode and a Ni cathode being used. The fraction of the current carried by the Cl ion is practically zero between 410° and 510°. Between 558° and 655°, Cl ion carries a considerable part of the current. It is significant that the temp. region in which the change from uni-ionic to bi-ionic conduction occurs is the same as the temp. region in which the slope of the cond. curve (log k *vs.* $1/T$) doubles its value. In the temp. range 558° to 655° the fraction carried by the Cl ion appears to decrease with increasing temp. This is thought to be a polarization effect.
E. R. Smith

Striated discharge in hydrogen and helium. JOHN ZELENY. Yale Univ. *Phys. Rev.* **29**, 609(1927).—With increasing pressure and under const. current, the striated discharge between cold electrodes in H passed through a min. and then through a max. with still higher pressures. The pressures at which reversals occur depend on the current and other factors. Measurements of stria distance for He, H, air, and O are also given. S. L. B. ETHERTON

A spectrometric determination of the intensity and energy distribution in the cross section of the positive column in helium and neon. GERHARD ZWIEBLER. Physik Inst., tech. Hochschule, Berlin. *Ann. Physik* **86**, 241–90(1928).—The intensity and energy distribution for 14 spectral lines of Ne and 3 of He have been detd. at 5 points on the radius of the positive column in these gases by means of a Kurlbaum spectrometer. The intensity decreases rapidly from the center of the beam to the wall of the tube. At a distance of $^1/_{12}$ the radius from the center the intensity had diminished to $^1/_2$ its value at the center. The % decrease in energy from the center of the column outward, with const. pressure, decreases almost proportionately with the current through the tube, and, with const. current, increases with the pressure. The intensity of the single spectral lines increases more than proportional to the increase of the current. A. J. KING

Mobilities of ions in hydrogen gas mixtures and the constitution of the ion. LEONARD B. LOEB. Univ. of Calif. *Phys. Rev.* **29**, 751(1927); cf. *C. A.* **22**, 1903.—Recent measurements of mobilities in HCl-air mixts. indicate that there is an increased concn. of HCl gas around the ion, the effect being greatest for the neg. ion. Expts. in the H_2-ether and H_2-NH_3 mixts. indicate the following. Small quantities of ether lower the mobility of the ion in H_2 abnormally, but the effect on the −ion can be calcd. from the law of mixts. Minute traces of NH_3 in H_2 increase the mobility of the +ion nearly to that of the −ion. More NH_3 in H_2 lowers both mobilities more than the law of mixts. demands. In a mixt. of NH_3, ether, H_2 the effect on the +ion could be calcd. from the observed combined effects of what the ether alone produced added to what the NH_3 would have produced on a normal +ion in H_2 without the increase due to NH_3 alone. These results can only be explained on the assumption that the ionized mol. or atom adds itself to at least one more mol. to make a +ion, a conclusion agreeing with that of Erikson obtained on other evidence. S. L. B. ETHERTON

Formation of negative ions. A. P. ALEXEIEVSKY. Univ. of Calif. *Phys. Rev.* **29**, 752(1927).—When an electron approaches a gaseous mol. the latter is polarized and attracts the electron with a force approx. $f = (D - 1)e^2/2\pi r^5N = K/r^5$ (Langevin's expression), where D is the dielec. const. of the gas, N is the no. of mols. per cc. of gas, e is the electronic charge, and r the distance between the electron and the center of the mol. The attached electron probably moves in an orbit, part of which lies within the mol. core. On the assumption the electron cannot move within the core all the time, it is shown that all possible periodic orbits within a circle whose radius $r = (Km)^{1/2}/p$, where m is the mass and p the angular momentum of the electron. If the least amt. of angular momentum an electron can have is one Bohr unit, all periodic orbits must lie within the circle of radius $R = 2\ (Km)^{1/2}h$, where h is Planck's const. For He and A, $R <$ radius of the core, and for gases with large dielec. const. R is $>$ the probable radius of the core. S. L. B. ETHERTON

Ionization of mercury vapor by λ2537. PAUL D. FOOTE. Bur. of Standards. *Phys. Rev.* **29**, 609(1927).—Measurements of the photoelec. effect in Hg vapor were made by the method of Mohler, Foote and Chenault (*C. A.* **20**, 1351). If I = illumination and Δi the photocurrent, the relation $\Delta i = AI^2/(I + BI)^2$ holds, where A and B are consts., from 25° to 60°. Admixed N_2 greatly increases and H_2 decreases the effect. Since the above relation approaches $\Delta i = AI^2$ for small intensities, 2 separately excited atoms are involved in the ionization process. The complete mechanism of the ionization process is considered in some detail. S. L. B. ETHERTON

Movements of striae in discharge tubes under varying pressures. L. H. DAWSON. Naval Research Lab., Washington, D. C. *Phys. Rev.* **29**, 610(1927).—On varying the pressure the striae of the column of a discharge tube move. By measuring the pressure with a Mcleod gage, curves of the movement have been obtained as a function of the pressure, distance between electrodes, diam. of tube, and density of the current, for wet and dry H, He, N, air, CO and CO_2. S. L. B. ETHERTON

Excitation of mercury vapor by ions. ERNEST J. JONES. Univ. of Minnesota. *Phys. Rev.* **29**, 611(1927).—Satd. Hg vapor at 90° as bombarded with +K ions from a Kunsman source and the resulting radiation from a field-free space was photographed through a quartz spectrograph. At 160 v. only the 2537 line appeared after 6 hrs.' exposure with an av. ion current of 1.5×10^{-8} amps. At 646 v. after 4 hrs. with ion current

of 2 × 10^{-5} amp. 2537 (1S − $2p_2$), 3126 ($2p_1$ − $3d_2$), 3132 ($2p_1$ − $3d_4$), 3650 ($2p_1$ − $3d_1$), 4046 ($2p_3$ − 2s) and 4358 ($2p_2$ − 2s) were obtained. Comparison with the spectra excited by the electrons shows (*a*) the efficacy of excitation by + ions is far less than that by electrons; (*b*) that it increases with the velocity up to 1200 v.; (*c*) that up to 1200 v. the probability of excitation to the $2p_2$ level is > than to higher levels; (*d*) up to 1200 v. the excitation to levels higher than $3d_{1,2,3}$ is not observed with 4 hrs.' exposure and current of 2 × 10^{-5} amp. S. L. B. Etherton

Inelastic collisions in ionized gas mixtures. Gaylord P. Harnwell. Princeton Univ. *Phys. Rev.* **29**, 611-2(1927); cf. *C. A.* **21**, 2427.—By means of a positive-ray app. the variation with pressure of the ionization by electronic impact in mixts. of rare gases with H_2 and N_2 was studied. In equal proportions of H with He, Ne and A, the no. of rare-gas ions decreased below a pressure of 0.05 mm. At this pressure the mean free path is about equal to the dimensions of the app. H_2 decreased slightly with the pressure. H_1 and H_3 increased. Similar results were obtained with N. The results are considered definitely to prove the existence of a type of collision of the second kind resulting in ionization by positive ions. S. L. B. Etherton

Equipotential surface electrons as an explanation of the packing effect. W. E. Deming. *Phys. Rev.* **31**, 453-65(1928).—Theoretical. With static models of the He nucleus, packing can be satisfactorily accounted for by postulating that the electrons and protons shall be equipotential surface distributions having the usual total charges and radii, whereas ordinary electrons account for only 10% of the effect. With dynamic models, neither kind offers a soln. B. C. A.

Electronic discharge from cold wires in intense electric fields. R. J. Piersol. *Phys. Rev.* **31**, 441-7(1928).—The curves obtained by plotting the potential gradient against the logarithm of the electronic current for outgassed W at 27° and −180° are not linear. B. C. A.

Studies on the electron emission from metals and its dependence upon the change of state of the material of the cathode. II. The fusion diagrams of silver, gold and copper. A. Goetz. *Z. Physik* **43**, 531-62(1927); cf *C. A* **21**, 3154.—The method described in the previous publication has been applied in the measurement of the electronic emission of Ag, Au and Cu taking place during the process of fusion and crystn. of these metals. Other phenomena are described which are observed when metals are fused or crystd. in a high vacuum. E. K.

The measuring of lags in discharge. Wm. Clarkson. Univ. of Utrecht. *Phil. Mag.* [7], **6**, 312-7(1928); cf. *C. A.* **21**, 3544 —Discussion of methods. G. G.

The reflection of electrons. S. Szczeniowski. *Compt. rend.* **187**, 106-9(1928).—For certain incident angles "reflection" of electrons at cryst. surfaces is to be expected. The angles of diffraction obtained by Davisson and Germer with a Ni crystal did not agree with the calcd. values. Using a method analogous to that of Debye and Scherer, G. P. Thomson obtained results agreeing with theory. S. repeats the expts. using cathode rays on the cleavage surface of a Bi crystal for 3 different potentials and for different incident angles and with electrons from a W filament. The preliminary results obtained confirm deductions from the theory and more accurate measurements will follow. S. L. B. Etherton

Secondary electrons from cobalt. Myrl N. Davis. *Proc. Nat. Acad. Sci.* **14**, 460-5(1928).—The secondary electron emission from Co is found to be very great, the maxima being more pronounced and the minima greater than the corresponding values for other metals. Fe and Ni roughly correspond in the type of function obtained, but the maxima shift toward higher primary energies with increasing at. wt. (not at. no.). Some technical details which are in controversy are discussed. W. T. R.

Diffraction of cathode rays by mica. I. Seishi Kikuchi. Inst. Phys. and Chem. Research, Tokyo. *Proc. Imp. Acad. Tokyo* **4**, 271-4(1928).—With cathode rays the attempt has been made to obtain patterns analogous to the Laue x-ray pattern. Fairly homogeneous rays from a gas tube were found satisfactory. The exptl. set-up is similar to that of G. P. Thomson (*C. A.* **22**, 1723). Thin sheets of mica were used as the diffracting medium. Plates of different thickness were tried. The exact dimensions are unknown but were probably about 10^{-4} cm. The cathode ray beam was usually perpendicular to the mica plate, but sometimes purposely tilted. Two general types of pattern resulted, depending upon the thickness of the mica plates. The thinner plates gave a simple pattern consisting of 3 series of parallel lines intersecting at about 60°, thus forming a triangular net, of which the net points appear as an array of spots. Enhanced spots near some of the net points also appear. Increasing the potential decreases the distance between the parallel lines, the product of this distance and the sq. root of the potential remaining nearly const. It is assumed that this pattern

represents the diffraction figure from a 2-dimensional lattice with scattering points arranged in an equilateral triangular network. Such an arrangement of atoms is possible from the symmetry of mica. The interference of waves from successive planes, which must exist in the mica sheet, would seem to have little effect. The distance between atoms, on this assumption, is 4.1 A. U. The enhanced spots are possibly indications of the 3-dimensional character of the mica sheet. II. *Ibid* 275–8.—Patterns of the second type, *i. e.*, from the thicker sheets of mica, are, unlike the first type, affected by the orientation of the sheet. The patterns generally have four elements: spots, rings and black and white lines. The distribution of these elements depends more upon the orientation of the mica sheet than on the potential. *Conclusions:* The spots are similar to Laue spots. The configuration of the concentric rings depends upon the specimen orientation, and apparently may be explained as due to diffraction from a linear array of atoms making a small angle with the cathode-ray beam. The cause of the lines is not clear. R. L. Hershey

Collisions of the second kind between zinc and mercury atoms. J. G. Winans. Univ. of Wis. *Phys. Rev.* **29**, 213(1927).—Evidence has been obtained that Hg atoms in the $2P$ state are effective in collisions of the second kind with Zn atoms. A quartz tube contg. Zn and Hg vapors was illuminated by nearly monochromatic light of λ 1849 ($1S - 2P$) obtained by a focal isolation method from a hot Hg arc. The Zn sharp triplet ($2p_{1,2,3} - 2s$) appeared very clearly in the secondary radiation and failed to appear when all wave lengths shorter than 2100 were absorbed from the exciting light by a sheet of thin glass. Similar results were obtained by using the water-cooled Hg arc and the Al spark as light sources. λ1849 has been photographed through an air path of 90 cm. The Zn lines which appear when various light filters are placed in the path of the exciting light from a Hg arc, give evidence that some Hg atoms in the $3d$ state transfer their entire energy to Zn atoms in collisions of the second kind. A calcn on the basis of the kinetic theory shows that, under these exptl. conditions, an excited Hg atom with an associated metastable state is probably about twice as effective in producing collisions of the second kind as one with no metastable state near it. R. L. Hershey

Impact polarization and the spinning electron. A. Ellett. *Phys. Rev.* **29**, 207–8 (1927).—In most cases lines of the Hg spectrum for which ΔR during the collision is ± 1 exhibit polarization of the type to be expected if the Zeeman levels for which $m = \pm 1$ are favored in excitation, whereas if ΔR in excitation is zero the assumption that the level $m = 0$ is favored lends to the correct conclusion. On the spinning-electron hypothesis these results may be interpreted by saying that when R changes the spinning electron turns over during the collision and gives to the atom a unit of angular momentum parallel to the electron beam, and to the magnetic field which may be applied in this direction without changing the resulting polarization. Likewise, $1s - 2p_1$ of Na should show zero polarization and $2p_2 - 3d_3$ of Th should show polarization, if the reorientation of the spinning valence electron relative to the orbital momentum is brought about by the colliding electron turning over. If this is not true, the latter should behave like D_2 of Na. R. L. Hershey

The variation of ionization in a short-period variable star. II. Second order ionization. Georges Tiercy. *Arch. Sci. Phys. Nat.* **10**, 5–18(1928); cf. *C. A.* **22**, 1537.—An equation is developed to express the ionization of the second order, similar to that of the first order except for altered coeffs. and a different entropy const. Conclusion: Ionization of the second order has not reached measurable proportions in S. V. Casseopeia, the Cepheid especially considered. The ionization Si^{++} is considered in relation to the varying temps. at different levels in other stars. W. T. Richards

Secondary electron emission from molybdenum. Albert W. Hull and J. M. Hyatt. General Electric Co. *Phys. Rev.* **29**, 214(1927).—A special 3-electrode tube was used, consisting of a short straight W filament in the axis of a long cylindrical Mo grid and plate. The tube was thoroughly exhausted, a small quantity of Cs introduced, the tube sealed off from the pump, and the plate bombarded with Cs positive ions at 600 v. for 5 hrs. The tube was then immersed in liquid air and the plate heated by induction until the plate current showed no change with continued heating. Measurements of plate current were made, as a function of grid and plate voltage from 0 to 2000 v. The fraction of the primary electrons which reached the plate was detd. by removing the tube from liquid air, reversing the potentials, and measuring the positive-ion currents from the filament K grid and plate. The no. of secondary electrons per primary electron was thus calcd. and found to increase from 0.45 at 20 v. to a max. of 1.23 at 900 v., decreasing to 1.04 at 2000 v. These values were reproducible at different times and in different tubes to 2%. R. L. Hershey

Secondary electron emission produced by positive cesium ions. J. M. HYATT. Union College. *Phys. Rev.* 29, 214(1927).—The source of positive ions, a short W filament maintained at about 1200° K. in the presences of Cs vapor, was mounted on the axis of a long, cylindrical Mo grid and plate. A potential of —600 v. was applied to the grid and potentials from +50 v. to —650 v. to the plate. While the plate was between +50 and 0 only secondary electrons from the Cs-covered grid reached it. When the plate potential became negative it caught positive ions in addition to secondary electrons. The plate current became const. at —50 v. and remained so until the plate potential reached that of the grid. Then the plate current suddenly increased 4% in consequence of the emission of secondary electrons from the plate. Further increase of positive-ion velocities was accompanied by a uniform increase of secondary electron emission. Similar observations were obtained with the grid maintained at 6 lower potentials. Detns. of the secondary electron emission from both grid and plate were in agreement and showed that the no. of secondary electrons per positive ion striking the Cs surfaces increased uniformly from 0.02 at 200 v. to 0.11 at 600 v.

R. L. HERSHEY

Effect of an electric field on a radiating hydrogen atom. K. L. HERTEL. Univ. of Chicago. *Phys. Rev.* 29, 214-5(1927).—Canal rays of H are passed into a high vacuum so that the natural decay of radiation may be observed and the changes in polarization produced by a transverse elec. field during the radiation process. The original polarization is always suddenly reversed when the field is applied so that the elec. component parallel to the field becomes stronger. This change must take place in less than 2 $\times$ 10^{-9} sec. In the uniform field the polarization gradually decreases to 0 or even reverses slightly. Measurements made with different velocities of rays showed the time required for this gradual return of polarization is about 4 $\times$ 10^{-8} sec. Photographs of rays emerging from the condenser showed an increase in polarization of the light emitted, the component parallel to the field again being stronger.

R. L. HERSHEY

The nature of gaseous ions. HENRY A. ERIKSON. Univ. of Minnesota. *Phys. Rev.* 29, 215-6(1927).—When ionizing rays are passed through O_2, N_2, H_2, CO_2 and A a positive ion and a negative ion are formed. These have intially the same mobility in air, *i. e.*, 1.87 cm./sec. per v./cm. in moderately dry air. In a fraction of a sec the initial positive ion changes into a final ion with a mobility of 1.36. The negative ions undergo no change. No greater mobility in air than 1.87 is observed, which value is the mobility of the simplest singly charged body present. The lack of dissociation, the nature of the ionizing process, the results in the case of H, the possible sepn. of the two groups of ions and the like mobility of the initial as well as the final ions, lead to the conclusion that an electron escapes from the mol. by the action of the ionizing agent The initial positive ion is thus formed. The free electron attaches itself to a neutral mol., thus forming the negative ion. These are two 1.87 bodies. The positive 1.87 body soon shares an electron with a neutra mol., forming the 1.36 two-mol. body 1.87 is characteristic of a one-mol. and 1.36 of a two-mol. body. R. L. HERSHEY

Ionized hydrogen molecule. A. H. WILSON. Emmanuel Coll., Cambridge *Proc. Roy. Soc.* (London) **A118**, 635-47(1928).—The model proposed for the ion H_2^+ consists of one electron and 2 protons. To a first approxn., since the mass of the electron is relatively negligible, the protons may be considered as at rest. The system is thus a particular case of the problem of 3 bodies and can be solved completely classically. Pauli, who did this, obtained a value for the energy of the normal state differing from the exptl. result inferred from the ionization potential and the heat of dissociation Niessen, who also did this, obtained the exptl. result by introducing half integer quantum nos. By purely mathematical reasoning, W. obtains an analytical result with values for the energies in the various states. No soln. is in general possible but solns only occur for certain distances apart of the nuclei. It seems these states are illusory and that there are no positive distances of the nuclei which gives real states.

S. L. B. ETHERTON

A new method of determining the mobility of ions or electrons in gases. R. J VAN DE GRAAFF. Queen's College, Oxford. *Phil. Mag.* [7], **6**, 210-7(1928).—The principle of the method is the same as that used for the detn. of the velocity of light by Fizeau, who employed a rotating toothed wheel as a periodic shutter to break up a beam of light into sections which travel a known distance and then again encounter the periodic shutter, which, depending on the time of arrival of the sections of the beam, either stops them or allows them to pass on. Thus the transmitted light may be observed as a function of the speed of rotation of the disk, and from this, by taking into account the geometry of the app., the velocity of light may be easily computed. The

app. used for the detn. of the velocity of ions works in an analogous way. An oscillating potential in combination with grids gives the shutter effect corresponding with that of the rotating toothed wheel of Fizeau. The mobility for H_2 is found to be 5.8 cm. at normal temp. and pressure. GEORGE GLOCKLER

Astrophysical estimates of ionization potentials of iron, yttrium and lanthanum. A. VIBERT DOUGLAS. *Nature* **121**, 906(1928).—From a study of the behavior of sensitive lines in the spectra of Cepheid variables it has been estd. that the ionization potentials are Fe 6.6, Y 6.6, La 4.9. These are in agreement with previously detd. values where available. W. T. RICHARDS

The distribution of energy among electrons rebounding from helium atoms. A. L. HUGHES AND L. W. JONES. Washington Univ. *Phys. Rev.* **29**, 214(1927).—A narrow beam of electrons of known velocity was directed in He at various pressures below 0.01 mm. A pair of slits selected those electrons rebounding at 90° ± 3°, and their distribution of velocities was measured by the magnetic-field method. The pressure used was sufficiently low to insure that the rebounding electrons had made but one collision. For electrons having energies ranging from 16 to 100 v., it was found that the rebounding electrons had exactly the same energy as they had before collision. It was noted that there were no electrons rebounding at 90° with a loss of energy corresponding to excitation or ionization. R. L. HERSHEY

The complete photoelectric emission from potassium. J. BUTTERWORTH. *Phil. Mag* [7], **6**, 1-16, 352(1928).—No evidence has been found for the existence of a positive photoelectric emission, and it has been shown that, if such an effect does exist, it is less than 10^{-7} times the negative emission, from the same surface, measured in these expts. It is shown that K has at least 2 work-functions corresponding to the wave lengths 9700 A. U. and 60,000 A. U. The results indicate that the "patches" of lower work function form a very small part of the whole surface, and can acquire the greater work function under the influence of prolonged illumination. GEORGE GLOCKLER

Progress and aims of absorption spectroscopy. G. SCHIEBE. *Z. angew. Chem.* **41**, 687-90(1928). E. H.

Photoelectricity. WM. BRAGG. *Proc. Roy. Inst. Gt. Brit.* **1928**, Jan., 11 pp.—An address setting forth some of the phenomena of the field difficult of explanation according to present theory. WILLIAM E. VAUGHAN

Relative probabilities of the photoelectric emission of electrons from silver and gold. F. K. RICHTMYER AND L. S. TAYLOR Cornell Univ. *Phys. Rev.* **29**, 353-4(1927).—More careful data than those reported in *Phys. Rev.* Jan., 1926, have been taken through the K absorption limit of Ag and Au, by using slits about 5 x-units wide. The value of R_L^K computed from the magnitude of the discontinuity in the mass absorption coeffs. through the limit depends entirely on the magnitude of the correction for scattering. L. D. R

New measurements upon the light-sensitiveness of crystalline selenium. A. M. MACMAHON. Univ. of Chicago. *Phys. Rev.* **29**, 219(1927).—A 3-parameter family of curves, showing the change in the elec. current through a single, well-tested specimen of cryst Se as a function of the time, when the intensity and wave length of the incident light and the applied potential difference are separately varied, is given. The expression $i - i_0 = A(1 - \epsilon^{-at}) + B(1 - \epsilon^{-bt})$, where i is the current and t the time of illumination and A, B, a and b are consts., fits the exptl. results well. The work is largely preliminary. R. L. HERSHEY

X-ray analysis of silver aluminum alloys. A. F. WESTGREN AND A. J. BRADLEY. Metallographic Institute, Stockholm. *Phil. Mag.* [7], **6**, 280-8(1928).—An x-ray analysis of the Ag-Al system has confirmed the statement of Petrenko (*Z. anorg. Chem.* **46**, 49(1905)), that it has 2 intermediate phases at ordinary temp., both formed through transformation in the solid state. As Petrenko also found, one of them is Ag_3Al. It is cubic, having an elementary cube with an edge of 6.920 A. U., contg. 20 atoms. It is isomorphous with β-Mn. The other intermediate phase, which is homogeneous in a range from 27 to 40 atomic %. Al is a solid soln. of close-packed hexagonal structure. Its lattice dimensions change continuously from a_1 = 2.865 A. U., a_3 = 4.653 A. U and a_3/a_1 = 1.625 when satd. with Ag to a_1 = 2.879 A. U., a_3 = 4.573 A. U. and a_3/a_1 = 1.588 when satd. with Al. GEORGE GLOCKLER

Further test of the theories of absorption of x-rays. F. K. RICHTMYER AND L. S. TAYLOR. Cornell Univ. *Phys. Rev* **29**, 606.—It was impossible to decide between Kramer's and de Broglie's theory of absorption. Present measurements on Mo (42), Ag (47) and Sn (50) and the ratio of K to Z absorption favors de Broglie but Kramer's theory gives a better value for the abs. magnitude of K at the K limit. S. L. B. E.

Investigation of metal films by x-ray analysis. KARL HOROVITZ. Univ. of Chicago. *Phys. Rev.* **29**, 352(1927).—By means of the focusing x-ray spectograph metallic films deposited in high vacuum by at. rays have been studied. The films were analyzed where they were formed and in vacuum. K films were investigated at temp. of liquid air. Mirrors 0.15 mm. thick gave a body-centered cubic lattice, $a = 5.15$.
L. D. R.

Possible dependence of frequency of characteristic x-radiation on the temperature of the target. J. H. PURKS AND C. M. SLACK. Columbia Univ. *Phys. Rev.* **29**, 352 (1927).—Water-cooled and standard Coolidge tubes were used to investigate a possible change of frequency of Mo $K\alpha$ with the temp. of the target. The energy used made the target of the second tube white hot. Negative results were obtained. L. D. R.

Velocity and number of the photoelectrons ejected by x-rays as a function of the angle of emission. E. C. WATSON. California Inst. Tech. *Phys. Rev.* **29**, 751–2 (1927); cf. *C. A.* **21**, 3309; **22**, 2320.—Magnetic spectra of the electrons ejected by x-rays from thin metallic films at angles between 0° and 180° with the x-ray beam have been measured by the method or Robinson, de Broglie and Whiddington. The max. velocity of ejection is the same in all directions. With thin foils of the heavier metals the no. of electrons ejected with this max. velocity is approx. the same. With foils of very light elements or with sputtered films that come under Wentzel's criterion, for single nuclear scattering, the no. of electrons ejected is greatest in a direction a little forward of the perpendicular to the x-ray beam. On the assumption that all electrons sent out from the atom go in the same direction the no. of electrons leaving can be calcd. by the theory of scattering. S. L. B. ETHERTON

Valence and Röntgen spectra. OTTO STELLING. Lund Univ. *Svensk. Kem. Tids.* **40**, 135–48(1928).—S. summarizes his 7 contributions on the relation of chem. constitution to Röntgen-ray to absorption spectra (*C. A.* 19, 3423, 2424; *Dis Lund* **1927**). The valence problem is stressed and instances are given wherein spectrum measurements clarified the constitution of org. compds. Eight tables give the K absorption spectra measurements by Bergengren (*C. A.* **15**, 207) and Lind (*C. A.* **15**, 3586; **16**, 3435). A. R. ROSE

The photoelectric effect of soft x-rays. G. B. BANDOPADHYAYA. King's College, London. *Proc. Roy. Soc.* (London) **A120**, 46–58(1928).—In an app. that was very carefully degassed at a pressure of 10^{-7} mm., 12 elements, C, Al, Fe, Co, Ni, Cu, Mo, Ag, Ta, W, Pt and Au, were subjected to the action of soft x-rays from a Cu anticathode at voltages ranging from 200 to 500 v. The photoelec. current was measured by an electrometer and the thermionic current with a micro-ammeter. The values of $\frac{\text{photoelec. current}}{\text{thermionic current}}$ are recorded for the above elements and also for Al, Fe, Ni, C, Ag, Au and Pt when the photoelec. plates were not degassed. The latter values were generally higher than those with the elements degassed. No simple relationship was discovered between photoelec. efficiency and at. no., the sensitivity of the elements under soft x-rays being quite comparable to that under ultra-violet light. Theoretically, the no. of photoelectrons liberated should be proportional to the voltage, a supposition that B. finds to be approx. true. MALCOLM DOLE

X-ray studies on the "nitrides" of iron. GUNNAR HÄGG. *Nature* **121**, 826–7 (1928).—X-ray examns. by the powder method have been made of Fe "nitrides" prepd. by passing NH_3 over pure Fe, prepd. by reducing Fe oxides with H_2. The structure is dependent only on the N content and not on the method or conditions of prepn. The max. N content is 11.3%. The "nitrides" are really solid solns. of N in Fe. At 0.2% N faint lines of a face-centered cubic lattice begin to appear; all α-Fe lines have disappeared at 5.7% N. The new lines remain fixed as N increases and indicate a unit cube of edge 3.789 A. U. somewhat larger than that of γ-Fe. However, this is called the γ-phase and is considered to be a solid soln. of N in γ-Fe. The Fe atoms are in a close-packed cubic array, with N atoms in the interstices. No evidence that the N atoms are regularly arranged appears. A new phase, ϵ, appears between 5.7 and 6.1% N. It is hexagonal close-packed, the unit cell remaining fixed in size at first, but beginning to increase between 7.3 and 8.6% N. The phase is estd. to become homogeneous between 7.5 and 8% N. The ϵ parameters are the $a = 2.695$ A. U., $c = 4.362$ A. U. Increase in N increases the parameters, c increasing relatively less than a. The ϵ phase is a solid soln. of N in hexagonal close-packed Fe. A thin Fe sheet nitrided at 450° for 4 hrs showed strong γ and weak ϵ lines.
R. L. HERSHEY

A new method of obtaining x-radiograms. K. V. VASIL'EV. *Trans. Inst. Econ. Mineral. Met.* (Moscow) **1928**, No. 34, 45–58.—The specimen is mounted in a circular

hole in the center of the film. The beam is bisected by the film, *i. e.*, the plane of the film includes the axis of the beam. The reflected rays are recorded as radial streaks originating at the center of the film. R. L. Hershey

The general x-radiation from mercury vapor. Wm. Duane. *Proc. Nat. Acad. Sci.* **14**, 450(1928).—A continuous x-radiation results from the impacts of electrons against Hg vapor atoms. It is not homogeneous either in the direction of the electron stream or normal to it, since in both cases it becomes more and more penetrating as it passes through successive layers of Al. The percentage intensity of radiation passing through successive Al sheets agrees well with the values calcd. from the law of D. L. Webster, which states that the x-radiation from an indefinitely thin target should have a max. of intensity at the short wave length limit, and should decrease beyond this limit with increasing wave length as the inverse square of the wave length.
W. T. Richards

Procedures for obtaining Debyegrams. K. V. Vasil'ev. *Trans. Inst. Econ. Mineral. Met.* (Moscow) 1928, No. 34, 36–44.—The paper is a review of the well-known methods of prepg. powders for Debye-Scherrer pictures. R. L. Hershey

X-radiation from gases. Albert Bjorkeson. Univ. Upsala. *Nature* **122**, 14–5 (1928).—A crucible contg Na was bombarded by electrons in a vacuum. A screen of brass, with a small Al window placed beside the crucible and a photographic plate constituted an x-ray pinhole camera. A blackening on the plate corresponding to the image of the crucible appeared when Na was in the crucible, no blackening showed when the crucible was empty. Similar expts. with S, using a vacuum spectrograph and a gypsum crystal as a grating, gave the K_α line of S. Five lines were obtained with the crucible elec. heated, an electron current of 90 milliamp. and a potential of 6000 v. The two strongest correspond to K_α and K_β; the others were too weak for wave-length detns. R. L. Hershey

A theory of the mechanism of crystal growth. Wheeler P. Davey. *Phys. Rev.* **29**, 206(1927).—It is suggested that crystn. proceeds, not uniformly along a plane surface, but along a three-dimensional lattice which is later filled in. This may be observed in the crystn. of photographic hypo from a supersatd. soln., in the contraction cavities of large-grain pure Cu crystd. in dry O_2-free H_2, in the end of a single crystal of Cu from which the molten Cu had been suddenly removed, on the surface of Cu cast in H_2, and in the surface skin surrounding single crystal Cu. The material crystg. later in the lattice is under tension, *i. e.*, all crystals are produced in a state of strain. This explains etching pits, "solution cavities," dendrite formation and the imperfections in crystals noted in x-ray work. R. L. Hershey

The intensity of the reflection of x-rays by crystals and the Compton effect. G. E. M. Jauncey. *Phys. Rev.* **29**, 206(1927).—The formula of Bragg, Darwin and James for the case of an ideally imperfect crystal, including corrections for extinction and temp. demands greater intensity at high orders than expt. shows. A further correction due to the Compton effect is suggested, it being supposed that only those electrons which are in orbital positions U such as to scatter unmodified rays take part in the cryst. reflection of x-rays. J.'s theory of the unmodified line gives the ratio of the numbers of electrons in the U and M positions (*C. A.* **20**, 2943). A calcn. of the quantity F in the Bragg, etc., formula can then be made from this ratio on the assumption that the electrons in the U position scatter as a whole. R. L. Hershey

The difference of the lattice constants of rock salt and of chemically pure sodium chloride. Tom. Barth and Gulbrand Lunde. *Z. physik. Chem.* **126**, 417–24 (1927).—The lattice const. of a natural rock salt was found to be 0.002 A. U. larger than that of pure NaCl. The const. of the natural rock salt is taken as standard at 5.628 A. U. and the pure NaCl then has a const. 5.626 A. U. The difference is attributed to small quantities of KCl present in the natural rock salt. R. L. Hershey

The application of a valve amplifier to the measurement of x-ray and photoelectric effects. C. E. Wynn-Williams. *Phil. Mag.* [7], **6**, 324–34(1928).—A valve amplifier for the measurement of ionization currents of the order of 10^{-12} amp., possesses certain advantages over other methods of measurement. Its usefulness, however, is limited in that it cannot always be operated if an induction coil or similar impulsive high-potential app. was at work in its neighborhood. For this reason, its use for the measurement of the ionization currents produced by x-rays has been ruled out. Under certain conditions, and provided that suitable precautions are taken to screen the app., the difficulties in using it for x-ray measurements can be overcome, and, in addn., when employed in conjunction with a photoelectric cell, it can be used for photometric work.
George Glockler

The action of x-rays on colloidal ceric hydroxide. J. A. V. Fairbrother. *Phil.*

Mag. [7], 6, 385–401(1928).—A quant. study is made of the viscosity changes produced in $Ce(OH)_4$ hydrosol by x-rays. In sols of low concn. and with increasing x-ray doses the viscosity decreases to a min., then increases rapidly and the sol sets to a rigid gel. In more concd. sols the spontaneous increase in viscosity which takes place when the particles are discharged masks the initial decrease. The sols become more sensitive to x-rays with age, and the doses required to produce the max. decrease in viscosity and to set the sol to a gel become very much smaller, indicating that the charge upon the particles is decreasing. When the position of min. viscosity is reached the sol sets spontaneously to a rigid gel within the course of a few hrs. An x-ray dose sufficiently in excess of that required to produce the max. decrease will set the sol to a gel immediately (cf. *C. A.* **21**, 3827). In a particular sol studied the particles decreased in size up to the position of min. viscosity. The % decrease in size was almost equal to that in viscosity. Beyond the min. point the particles increased in size, reaching a max. at the setting point of 1.6 times the normal value. GEORGE GLOCKLER

The thermal measurement of x-ray energy. J. A. CROWTHER AND W. N. BOND. Univ. of Reading. *Phil. Mag.* [7], 6, 401–22(1928).—The energy of a beam of x-rays has been measured by converting it into heat in a calorimeter. The energy absorbed from the radiation for the formation of one pair of ions in air is 42.5 "volts." This value is const. over the range of wave lengths employed in the expts. The quantity of electricity, I, measured in electrostatic units across 1 cc. of air at 18° and normal pressure is given by $I = 1.70 \times 10^{-4} E\tau$, where E is the total x-ray energy in ergs which has passed through the gas, and τ is the "true" mass coeff. of absorption. The relation cannot be applied to a heterogeneous radiation, because of the impossibility of detg. τ for such radiation. GEORGE GLOCKLER

The determination of the atomic scattering power for x-rays from powders of gold, silver and aluminum for CuKα radiation. J. BRENTANO. Manchester University. *Phil. Mag.* [7], 6, 178–91(1928).—Expts. are described intended to obtain comparative values for the scattering power of Au, Ag and Al. The measurements are made with small powder particles, and a method is employed in which the intensities are measured from composite layers. Some points concerning this method, which makes it possible to overcome certain difficulties in measuring the intensities of x-ray reflections from powders are discussed, and the procedure is indicated for evaluating the photographic records. The results of the expts. indicate that, for the elements of high at. wt. examd. in the state of very fine powders, the scattered intensities increase considerably less rapidly than F^2 (negative charge at the atom) and that better agreement is obtained by assuming the scattered intensity proportional to F. GEORGE GLOCKLER

Multiple ionization and the absorption of x-rays. F. K. RICHTMYER. Cornell University. *Phil. Mag.* [7], 6, 64–88(1928).—The question has been raised: Are there in x-ray absorption spectra discontinuities corresponding to the so-called "spark" lines analogous to the K,L,K.... discontinuities corresponding to the diagram lines? The present evidence seems to indicate that the processes which give rise to the spark lines are secondary processes, and we should not, therefore, expect to find evidence concerning their origin in absorption spectra. But in any event the spark lines are so weak compared with the diagram lines that existing data on x-ray absorption-coeffs. are not sufficiently precise to detect such discontinuities as might occur. It is shown that a straight line (Moseley graph) results when one plots the square root of the difference in frequency between a spark line and its "parent" line as a function of at. no. This suggests the possibility that spark lines may originate in two-electron transfers. In making precise measurements of x-ray absorption-coeffs., it is necessary to use slits sufficiently narrow to eliminate the "slit-width" error. The magnitude of this error is computed for one special case, and it is shown that with slit-widths as wide as some which have been used, errors as large as several percent may occur in the neighborhood of 0.3 A. U. GEORGE GLOCKLER

Two electron multiplets of the first and second long periods. H. C. WHITE AND R. C. GIBBS. Cornell Univ. *Phys. Rev.* **29**, 359(1927).—W. and G. have found that three characteristic multiplets arising from two valence electron systems of the first and second long periods follow the so-called regular and irregular doublet laws. The multiplets have been extended in the first long period from Ca_I to Cr_V, and in the second long period from Sr_I to Cb_{IV}. L. D. R.

The series relation of the neon spectrum. Y. ISHIDA. Supplement to *Sci. Papers Inst. Phys. Chem. Research* 9, No. 6, 3 pp. W. F. MEGGERS

A fine quantum analysis of certain terms of thallium I. MASAMICHI KIMURA. *Sci. Papers Inst. Phys. Chem. Research* **154**, 51–6(1928).—An analysis of the hyperfine structures of Tl lines observed by Mohammad and Mathur (*C. A.* **22**, 2885) suggests

that the 2 p_1 and 3 d_3 terms are each three-fold with interval ratio of 3:2, while 2 p_2, 3 d_1 and 2 s are triple with interval ratio 2:1. Assigning fine quantum nos. to the sublevels and arranging the fine structure components as multiplets indicates that the selection principle governing the occurrence of the observed components is the same as that of inner quantum nos.; if a fine quantum no. of a subterm is denoted by f, then its selection principle is expressed by $\Delta f = \pm 1$, or 0, excluding the change from $f = 0$ to $f = 0$. W. F. MEGGERS

Limits of ultra-violet transmission of certain inorganic compounds. MASAMICHI KIMURA AND MATAICHIRO TAKEWAKI. *Sci. Papers Inst. Phys. Chem. Research* 155, 57–64(1928).—The ultra-violet transmissions of a no. of simple inorg. compds. in a solid state were examd. by reducing the samples to fine powder, filling a hollow quartz wedge with these powders and photographing the spectrum of a condensed spark projected on the spectrographic slit through the wedge. Curves are sketched to represent the spectrographic records. Examn. of these curves shows that colorless compds. of alkali and alk. earth metals are more transparent to the ultra-violet than the compds. of other metals. In halogen compds. of metals the ultra-violet limits of the transmission displace towards the red in the order of chlorides, bromides and iodides. Colorless chlorides of metals are generally the most transparent compd. of the metals. Nitrates of Li, Na, K, Mg, Zn, Cd, Ca, Ba, Al, Pb, Bi, Co, etc., cut off ultra-violet below 320μ; this is caused by the presence of the NO_3 radical. Oxides of Cd, Pb, Sn, Bi, Sb, Zn, Hg, Co, Fe, Ni and Ag cut off ultra-violet strongly but those of Mg, Ca and Al transmit it. All of the sulfides examd. absorbed the rays strongly. Comparison of the ultra-violet limits of transparency of metals in each group of the periodic table shows that in the groups of (Li, Na, K), (Mg, Zn, Cd) and (Sn, Pb) the limit shifts towards the red as the at. wts. of the metals increase, while in the group (Ca, Sr, Ba) the reverse seems to be the case. W. F. MEGGERS

Technic of spectral analysis. TR. NEGRESCO. *J. chim. phys.* 25, 216–33(1928).—A flame of the alloy to be analyzed was obtained by causing the air that is to be used in the burner to blow over a spark from 2 electrodes of the metal. The spark and arc of the metal were also studied. The images were projected into the slit of the spectrograph by means of a quartz lens. The spectrograph was so constructed that 20 spectra, one above the other, could be obtained on a single photograph; it could be used in the region between the 2 lines of Fe, λ2309 and λ6380 A. U. To verify lines sought for, Co and Ba were used as reference spectra. The developer used consisted of 1 l. H_2O, 10 g. hydroquinone, 40 g. Na_2SO_3 and 55 g. Na_2CO_3. A fresh soln. was used for each plate. Errors are possible due to the app., sensitivity of the plates and reading of the spectrograms. N. does not believe that the spectrum of an element is independent of the compd. in which it is found. E. G. VANDENBOSCHE

Predicted lines of Cr II in the spectra of the sun and of α Persei. THEODORE DUNHAM, JR. AND CHARLOTTE E. MOORE. *Astrophys. J.* 68, 37–41(1928).—In the spectra of the sun and of α Persei 33 previously unidentified lines have been established as members of the first spark spectrum of Cr. These lines have been identified on the basis of combinations of various terms of Cr II, and although they have not been found as emission lines in lab. sources, yet they occur as absorption lines in the solar and stellar spectra. C. C. KIESS

The presence of the rare-earth elements in the sun. CHARLES E. ST. JOHN AND CHARLOTTE E. MOORE. *Astrophys. J.* 68, 93–108(1928).—Ten rare-earth elements are present in the sun, as shown by the agreement of lines of their spectra with hitherto unidentified Fraunhofer lines. These elements are in the ionized state; they are La, Ce, Pr, Nd, Sm, Eu, Gd, Dy, Er and Yb. Probably present but not established with certainty are Il, Tb, Ho, Tu and Lu. These elements lie at low levels in the sun, being close to the photosphere, and exhibit characteristics which differentiate them from the lines originating in the neutral and ionized atoms of other elements. C. C. KIESS

... Liquid O and gaseous O at high pressure exhibit a no. of absorption bands between 3825 A. U. and 2490 A. U. which lie just to the red of a broad continuous band and increase in intensity with decreasing wave length. These bands are attributed to the mol. O_4. When the wave nos. of certain of these bands are plotted against arbitrary nos. in sequence it is seen that the bands form a progression. From the heat of dissociation of O_4 into O_3 and O the beginning of the broad absorption band is calcd. at 2470 A. U., which is close to the observed position. C. C. KIESS

The use of quartz rod or sphere for condenser in spectroscopy. H. NAGAOKA.

Sci. Papers Inst. Phys. Chem. Research (*Tokyo*) **8,** supplement no. 1, 1-3(1928). (In English.)—A quartz cylinder with one end plane and the other spherical is a useful means of concg. the faint light from an extended source on the slit of a spectrograph. A quartz sphere or a hemisphere may be similarly used. C. C. Kiess

The Stark effect of Balmer series at high field. Y. Ishida and S. Hiyama. *Sci. Papers Inst. Phys. and Chem. Research* (*Tokyo*) **9,** 1-14(1928). (In English.)—New observations of the Stark effect for members of the Balmer series of H have been made for very high elec. fields. The intensities of the components have been measured with microphotometers and the results have been compared with the different theories including the second- and third-order effects. On the whole the results appear to satisfy best the requirements of the wave mechanics both in respect to intensity and deflection. C. C. Kiess

Interferometer measurements of wave lengths in the vacuum arc spectra of titanium and other elements. C. C. Kiess. *Bur. Standards J. Res.* **1,** 75-90(1928).—Wave lengths of more than 300 lines of Ti I and Ti II as emitted in a vacuum arc have been measured with the Fabry-Perot interferometer. The spectral region covered extends from 6743 A. U. in the red to 2941 A. U. in the ultra-violet. For many of the lines the accuracy of measurement exceeds 1 part in 6,000,000; for the majority it exceeds 1 part in 4,500,000. From terms calcd. from lines measured near the Ne lines, which served as standards, it was possible to calc. the wave lengths in the blue and violet remote from the standards. The agreement between calcd. and observed wave lengths indicates that there is no error of scale affecting the results. In addition to Ti, some wave lengths are given for Fe, Cu, Ca, Ba, Na, Al, V, Cr, Mn and Ni. C. C. Kiess

The Compton effect and polarization. P. Lukirskii. *Nature* **122,** 275-6(1928).—Hard x-rays in the wave-length interval from 0.07 to 0.1 A. U. were directed to a block of paraffin from which secondary radiation was scattered. In consequence of the Compton effect the wave lengths of the scattered rays were increased. The secondary rays were directed to a second block of paraffin from which tertiary rays were scattered. The intensities of these were measured in different azimuths with respect to the elec. vector of the secondary rays. The results—max. intensity in a direction normal to the vector, min. intensity in the direction of the vector—show that the modified rays are polarized in the same manner as they should be in the case of classical scattering. C. C. Kiess

The Stark effect at very high fields. Yoshio Ishida. *Nature* **122,** 277(1928).—With elec. fields of 650 kv. per cm. the He line 7066 A. U. and the Li line 6702 A. U. hitherto not observed to be affected, were both shifted to the violet. A large no. of Ne lines were also found to exhibit complicated Stark-effect patterns; and for H_α the relative intensities of the *p* components were found to be in the ratio 22:65:45, a result in good accord with the requirements of the wave mechanics. C. C. Kiess

Molecular spectra in the extreme infra-red. C. V. Raman and K. S. Krishnan. *Nature* **122,** 278(1928).—The frequency differences between rays incident on a substance and the new rays in the light scattered by it, give the mol. frequencies of the scattering substance. This furnishes an accurate and powerful method of exploring mol. spectra, especially in the infra-red. In the case of CCl_4 three hitherto unknown infra-red lines, thus discovered, are 45.4μ, 31.8μ and 21.7μ. C. C. Kiess

Variation with state of the optical constants of cesium. J. B. Nathanson. Carnegie Inst. of Tech. *Phys. Rev.* **29,** 369(1927); cf. *C. A.* **19,** 1809.—At 23° and 33° the optical consts. of Cs were detd. for the solid and liquid states, for wave lengths 5400, 5890 and 6410 A. U. Changing from the solid to the liquid state the angle of azimuth of restored plane polarization and the phase difference between the component of the light vector parallel and perpendicular to the plane of incidence changed very little. L. D. R.

Zeeman effect and the structure of the arc spectra of copper and rhodium. L. A. Sommer. Harvard Univ. *Phys. Rev.* **29,** 358(1927); cf. *C. A.* **21,** 704.—S. agrees with Shenstone in the classification of the doublet term group ^2P, ^2D, ^2F, but does not agree regarding the classification of the higher doublet term group. L. D. R.

Some relations in the spectra of stripped atoms. R. C. Gibbs and H. E. White. Cornell Univ. *Phys. Rev.* **29,** 359(1927).—Starting with known values of the arc and spark spectra in one-electron systems in all three of the long periods, the first pair of doublets in the principal series for stripped atoms as far as Mn_{VII} in the first long period, Zr_{IV} in the second long period, and Pr_V in the next period have been recognized. The first pair of inverted diffuse doublets with satellite have been found for Sc_{III}, Ti_{IV} and V_V. Evidence indicates that Sc_{III} presents, as predicted by Bohr, a closer binding in a *d* orbit than either in a *p* or an *s* orbit. L. D. R.

Energy-level studies on metallic vapors using a high-temperature tungsten furnace. O. S. Duffendack and J. G. Black. Univ. of Mich. *Phys. Rev.* **29**, 358(1927).—Cu vapor yielded new absorption lines at 2618.37, 2824.39, 2882.81, 2961.19, 3010.87, 3194.09 and 5782.08 all originating in the metastable $^2D_{2,3}$ level. Cu lines 3247, 3274, 5106, 5700 and Cu hydride bands were found in emission. All five lines originated in $2^2P_{1,2}$ level. This state was reached by absorption of resonance radiation—not thermal excitation. No absorption lines originated in this level. L. D. R.

Spectra of the high-current vacuum arc. Arthur S. King. Mt. Wilson Observatory. *Phys. Rev.* **29**, 359(1927).—Arcs of Fe, Cr, Ti, Mg, Cu and Si were studied in a vacuum chamber at about 5 mm. Hg under high current. The central stream of this arc at 1500 amp. and 110 v. is intensely bright and shows complete ionization. L. D. R.

Absorption spectra in the extreme ultra-violet. J. J. Hopfield. Univ. of Calif. *Phys. Rev.* **29**, 356(1927).—Under widely varying pressure, absorption spectra of N_2, air, C_2H_2 and CO were obtained. Selective absorption and a region of contiguous absorption on the short wave-length side are shown. C_2H_2 shows band absorption beginning at λ2300. "Four or five bands of an apparently new system in CO begin with either λ1696 9 or 1664.4 as the 0-0 band and continue with λλ1634.0, 1604.9, and 1577 6 as consecutive members." L. D. R.

Critical potentials of iron. Richard Hamer and S. Singh. Univ. of Pittsburgh. *Phys. Rev.* **29**, 608(1927).—The critical potentials of Fe were investigated up to 132 v. A long quartz tube enclosing 2 electrodes consisting of a central iron rod and a concentric iron cylinder was externally heated and breaks in the current-potential curve were taken to indicate crit. potentials. Twenty such values are given and the method is developed to differentiate between multiple and fine-structure potentials. S. L. B. Etherton

Multiplets in the spectra of vanadium. III. R. C. Gibbs and H. E. White. Cornell Univ. *Phys. Rev.* **29**, 606–7(1927).—Triads of the multiplets of V_{III} have been identified, the initial state is given by one 4p electron and two 3d electrons. In the final state the 4p electron has shifted to the 4s orbit. The sepns. of the $^4F_{2,3,4,5}$ levels closely agree with Lande's interval rule and the relative intensities of the lines in the multiplets conform to the usual rule. A comparison of the data for 1-, 2-, 3 electron systems of Sc, and Ti and V shows that the addn. of first one and then a second d electron caused not only an increase in the multiplicity but also successive shifts in the radiated lines towards the longer wave lengths by very nearly the same frequency interval. A multiplet of Cr has also been identified S. L. B. Etherton

Emission of light by flames containing sodium and absorption of light by mercury vapor. H. A. Wilson. Rice Inst. Texas. *Proc. Roy. Soc.* (London) **A118**, 362–6(1928). —The results found by Gouy sustain the equation $I = A\rho d/\sqrt{\rho dB}$, I being the light intensity perpendicular to the flame surface, ρ is the amt. of Na per unit vol., where d is the thickness of the flame, and A and B are consts. When ρd is not very small B may be neglected and the expression may be written $I = A\sqrt{\rho d}$, *i. e.*, the light intensity is almost proportional to the root of the amt. of Na in the flame. The substance which emits the light cannot be represented by an equation such as NaCl + HOH = NaOH + HCl for then the intensity will vary as the root of the Na concn. If the light is due to free metallic Na formed by the completely dissocd. NaCl, the intensity will be proportional to the amt. of Na, did not absorption occur by the Na atoms. The square-root law may be explained by assuming that the Na atoms absorb light at the centers of the D lines and treating the Na atom as a simple oscillator and making allowance for viscous resistance to motion, the elec. intensity in the light at the atom and the charge on the particle. The expression deduced has been applied to the recent results of Hughes and Thomas (*C. A.* **22**, 25) on the absorption of resonance radiation by the Hg vapor. Conclusion: The consistent view is that the atoms absorb light like simple damped oscillators. S. L. B. Etherton

Ultra-violet absorption spectra of anthracene, phenanthrene and anthraquinone. A. Castille. *Bull. acad. roy. méd. Belg.* [5], **8**, 74–82(1928); cf. *C. A.* **22**, 3019.—Anthracene has 10 bands between 3800 and 2850 A. U. and moreover 2 bands in the extreme ultra-violet Phenanthrene has 17 bands which can be divided in 3 groups: (1) between 3900 and 3000 A. U., 10 bands, (2) between 3000 and 2600 A. U., 5 bands, (3) in the extreme ultra-violet 2 bands. Anthraquinone: 5 bands between 4250 and 3600 A. U., 1 large band between 3500 and 2850 A. U., and 4 bands between 2800 and 2300 A. U. R. Beutner

A modified Hartmann diaphragm. J. R. Green. *J. Soc. Chem. Ind.* **47**, 224T

(1928).—With the usual 3-aperture Hartmann diaphragm, if more than 2 elements are to be looked for, a wave-length scale has to be used to identify the lines in the comparison spectra. By cutting the diaphragm in a step-wise and inverted step-wise pattern, the position of a particular comparison spectrum and the length of the lines in it identify the position of the diaphragm when the spectrogram is taken and therefore the element to which it belongs. The need for a wave-length scale is thus avoided provided the comparison spectra are given only short exposures. J. H. PERRY

The spectrum of triply ionized antimony, Sb IV. J. B. GREEN AND R. J. LANG. *Nature* **122**, 241(1928).—The following groups have been identified in the spectrum of Sb IV: a $^3P^3S$ multiplet, lying between 805 A. U. and 861 A. U.; a very strong $^3P^3D$ multiplet; between 873 and 940 A. U.; a $^3D^3F$ multiplet, between 2077 and 2113 A. U.; and a possible $^3P^3P^1$ group between 1051 and 1193 A. U. In addn., a $^1S^3P$ line and $^1S^1P$ line give an est. of 340,000 cm.$^{-2}$ for the lowest ^1S level, corresponding to an ionization potential of about 42 v. H. F. JOHNSTONE

New facts concerning the diffusion of light in crystals. G. LANDSBERG AND L. MANDELSTAM. *Compt. rend.* **187**, 109-11.—In *C. A.* **22**, 3837 L. and M. described a new effect observed when a spectrum of light is diffused by certain transparent crystals. Some of the "principal rays" of a Hg lamp are accompanied in diffused light by satellites displaced towards the red, whose frequency differs by a const. value from that of the principal ray. Raman and Krishnan (*C. A.* **22**, 1907) have published observations on the change in wave length in the light spectrum when diffused by certain liquids and gases. Apparently the phenomena are analogous. New results are obtained with light diffused through quartz and Iceland spar, these being the discovery of satellites symmetrically displaced towards the violet but much weaker than the former satellites. From $\lambda = 2482$ A. U. to $\lambda = 4358$ A. U., L. and M. found 72 satellites for quartz and 18 for Iceland spar whose positions are given in the paper. Five parallel series for quartz and 2 for Iceland spar are found. The value of $A\nu_i$ is probably equal to the frequency ν_i of the real vibration of the crystal. S. L. B. ETHERTON

The negative absorption of radiation. C. V. RAMAN AND K. S. KRISHNAN. *Nature* **122**, 12-3(1928).—Careful measurements of the scattering of monochromatic light by liquid C_6H_6 shows the presence of lines of modified frequency in the scattered radiation. The difference between the incident and scattered frequencies is exactly equal to an infra-red frequency of the mol. C_6H_6, radiated with light from a Hg arc, which has been filtered of all but the 4358.3 A. U. group of lines, shows the brightest scattered lines at wave lengths longer than 4358.3 A. U. There are two, however, at shorter wave lengths, and their frequencies exceed that of the 4358.3 line by the infra-red frequencies of the mol. This indicates the presence in the liquid of mols. more highly energized than normal, and that the incident radiation induces a return to a lower state of energy, *i. e.*, there is neg. absorption of radiation. R. L. HERSHEY

Spectroscopic interpretation of the magneton numbers in the iron group. A. SOMMERFELD AND O. LAPORTE. *Phys. Rev.* **29**, 208(1927).—For the spectroscopic interpretation of the measured magneton numbers for the ions of the first long period an av. of the $j.g$-values for the different levels of the polyfold ground-term must be taken. This was not necessary for the paramagnetism of the rare earths since the sepns. $\Delta\nu$ are so large that only the lowest level needs to be considered. The exact formula for the magneton no. (in Weiss-units) becomes: $\mu W = 4.97\ \Sigma N_j j(j+1)g(j,l,s)^2/(\Sigma N_j)^{1/2}$; j, l and s are the quantum nos. of the level in question and N_j is the weight: $(2j+1)(-hc\Delta\nu/kT)$. The terms which are assumed to represent the normal state of the ions are computed according to the Stoner Periodic System, the rules of Pauli and Hund being used. If the lowest term is of the S type the magnetic moments computed in the old fashion and those according to this formula must furnish the exact measured value; this is the case for Fe^{+++} and Mn^{++}. The Heisenberg-Schrödinger quantum mechanics do not alter the above formula. R. L. HERSHEY

The absorption spectrum of antimony vapor. R. V. ZUNSTEIN. *Phys. Rev.* **29**, 209(1927).—Mols. of Sb vapor slowly admitted into a hot C tube at about 1400° undergo dissocn. into atoms. The at. absorption spectrum was studied. The arc lines 2311.50, 2175.88, 2068.38 were strongly absorbed. 2023.86 and 2127.46 were absorbed less strongly. All 5 absorption lines come from the $3d_1$ state, which is the normal state of the atom. R. L. HERSHEY

Band spectrum, continuous emission, and continuous absorption of fluorine gas. HENRY G. GALE AND GEORGE S. MONK. Univ. of Chicago. *Phys. Rev.* **29**, 211(1927).—The band spectrum consisting of 10 bands between 5100 A. U. and 7200 A. U. has been photographed, a concave grating spectrograph being used. The zero points of the bands are given by $\nu = 17438.8 + (1104.9n' - 2.9n'^2) - (1071.5n'' - 9.9n''^2)$, yielding

frequencies, ν_0 = 19637.0, 18540.8, 17438.8, 16377.2, 15335.3, 14325.0; having vibrational quantum nos. $n'n''$ = 2,0; 1,0; 0,0; 0,1; 0,2; 0,3, resp. Analysis of the bands at ν_0 = 17438.8 and ν_0 = 16377.2, having the same initial vibration frequency, and satisfying the combination $R(m) - P(m)$, gives $2B = 3.8 \pm 0.4$, or, $J = 14.5 \times 10^{-40}$. A peculiarity of these bands is the increasing fuzziness of the lines from band to band toward the red. For exptl. reasons the emitter is believed to be the F_2 mol. In a spectrogram obtained by using a spark discharge in F 2 continuous emission bands are shown at approx. 2800 A. U. and 2600 A. U. Spectrograms of the absorption of F have been made, using gas columns, at atm. pressure, as short as 7 cm. and as long as 3 m. Continuous absorption occurs to the violet of 4100 A. U. No line absorption spectra were found. R. L. Hershey

Intensity relations and electronic states in spectra of diatomic molecules. Robert S. Mulliken. N. Y. Univ. *Phys. Rev.* 29, 211(1927).—The correspondence principle predicts definite intensity relations for P, Q, and R, band lines in mols. having a tional energy term $F = B(j^2 - \sigma^2) + \ldots$, provided σ is an electronic quantum no. corresponding to a precession about the internuclear axis (along which the angular momentum $\sigma h/2\pi$ is directed). Hönl and London have given equations for the 3 possible cases $\Delta\sigma = 0, \pm 1$. Let I represent intensity. Then for low values of j, the theory predicts $I_R > I_P$ if σ decreases during emission, but $I_P > I_R$ if σ increases, and $I_Q = I_P + I_R$, approx., in both cases. For $\Delta\sigma = 0$, the prediction is $I_P = I_R$, with I_Q small and falling with increasing j. Various band spectra have recently been interpreted by the writer as corresponding to electronic transitions $^1S \longrightarrow {^1S}$ (CuH type), $^1P \longrightarrow {^1S}$ (AlH), $^1D \longrightarrow {^1P}$ (H_2 λ5733), etc., with $\sigma = 0$ for ^1S, $\sigma = 1$ for ^1P and $\sigma = 2$ for ^1D states. These interpretations, and the proviso mentioned as to the nature of σ are completely confirmed in a comparison of available intensity data with the predictions of the theory. R. L. Hershey

Carbon monoxide band excitation potentials. Ann B. Hepburn. *Phys. Rev.* 29, 212(1927).—A hot-filament 3-element tube was used for visual and photographic detns. of the excitation potentials of the 0,0 bands of the Ångström, Comet's Tail, First Negative Deslandres, and Baldet-Johnson band systems of CO. Computations by Birge indicate that λλ4511, 4880, 2190, 3794 should be produced by electrons having a min. velocity corresponding to 10.7, 16.7, 19.8 and 19.8 v., resp. These expts. confirm the computations with an exptl. error (±0.1 v.). R. L. Hershey

Hydrocarbon bands. Frank C. McDonald. Univ. of Chicago. *Phys. Rev.* 29, 212(1927).—Two new bands, λ2264 and λ2367, found when CH_4 was led into a Wood tube and excited by a condensed discharge also appeared when acetylene, mixed with He, was excited by a transformer discharge. These bands have been arranged in P and R branches with a single missing line. They belong to the same system with a common initial state. The possibility of a CH ion as a carrier is considered. New plates with a high dispersion of a band, λ3143, originally reported by Fortat, have been obtained, but appear to show a somewhat different structure of the band than given by Fortat. R. L. Hershey

The titanium bands. R. T. Birge and A. Christy. *Phys. Rev.* 29, 212(1927).—The 28 well-known Ti bands have been arranged in one system and vibrational quantum nos. assigned. The heads are given by:

$$\nu = \left.\begin{matrix} 16{,}350.0 \\ 19{,}340.0 \end{matrix}\right\} + (833.1n' - 4.5n'^2) - (1003.5n' - 4.5n^2 - \ldots)$$

with an av. residual of 1 cm.$^{-1}$. The electronic energy change and the frequencies of vibration show a close correlation with the corresponding values for the Al bands, which are now definitely known to be due to AlO. The distribution of intensity among both the vibrational and rotational states is closely the same for the 2 mols. A preliminary est. of the moment of inertia shows a similar correlation. This seems to indicate that these bands are due to TiO and not to TiO_2. R. L. Hershey

Optically excited iodine bands with alternate missing lines. *R. W. Wood. The Johns Hopkins University and F. W. Loomis, New York University. *Phil. Mag.* [7], 6, 231-8(1928).—Some direct exptl. evidence is reported that, as predicted by the wave mechanics, the rotational states of symmetrical mols. are divided into two classes between which transitions do not occur. These classes of states are those whose eigenfunctions are resp. symmetrical and anti-symmetrical in the positional coördinates of the nuclei. The evidence has been obtained as the result of improvements in the technic of exciting iodine fluorescence. George Glockler

The Zeeman resolution of the oxygen line at 5577 A. U., the auroral green line. J. C. McLennan, J. H. McLeod and Richard Ruedy. Univ. of Toronto. *Phil.*

Mag. [7], **6**, 558–67(1928); cf. *C. A.* **21**, 1060, 1225.—The paper deals with a more exact detn. of the longitudinal Zeeman effect of the O green line λ5577. The line appears to be a forbidden transition. GEORGE GLOCKLER

The power relation of the intensities of the lines in the optical excitation of mercury. R. W. WOOD AND E. GAVIOLA. Johns Hopkins Univ. *Phil. Mag.* [7], **6**, 352–6(1928).—It was pointed out (*C. A.* **21**, 3830) that the anomalous behavior of 3650 was probably due to the fact that the line appears in fluorescence as the result of three successive absorption acts. Its intensity must then be proportional to the product of the intensities of the 3 exciting lines producing it, the absorption of which originates 3650. If the ratio of the intensities of the lines in the arc is const., the product of the intensity of 3 arc lines is proportional to the cube of the arc intensity. 3650 should vary then with the cube of the intensity of the exciting light. On the other hand, nearly all of the other lines that appear in fluorescence are originated by two successive absorptions. Their intensity must then be proportional to the square of the intensity of the arc. And finally the intensity of the resonance line 2537 should vary directly with the intensity of the arc. This prediction has now been proved quant. GEORGE GLOCKLER

New bands in the secondary spectrum of hydrogen. D. B. DEODHAR. King's College, London. *Phil. Mag.* [7], **6**, 466–79(1928).—D. describes 7 new bands in the secondary spectrum of H_2 situated in the yellow region (cf. *C. A.* **21**, 704). G. G.

The fine structure of three infra-red absorption bands of ammonia. G. A. STINCHCOMB AND E. F. BARKER. Univ. of Mich. *Phys. Rev.* **29**, 213(1927).—With a grating spectrometer with a rock-salt fore-prism, the fine structure of the 1.98μ, 2.2μ and 3.0μ bands of NH_3 was detd. The shape of the curve and the frequency differences for the 3.0μ band are in agreement with the results of B. J. Spence, although somewhat different values are assigned to the wave lengths. The 1.98μ band consists of about 30 lines spaced with fair regularity throughout the entire band. Its center is marked neither by an absent line, nor by a single zero branch of great intensity like that at 3.0μ. The frequency difference between adjacent lines approximates 10.0 cm.$^{-1}$ The 2.2μ band is extremely irregular, making the location of the lines somewhat uncertain and yielding no obviously characteristic frequency difference. No zero branch is apparent. R. L. HERSHEY

Factors governing the appearance of the "forbidden line" 2656 in the optical excitation of mercury. R. W. WOOD AND E. GAVIOLA. Johns Hopkins Univ. *Phil. Mag.* [7], **6**, 271–6(1928).—The necessary condition for the appearance of the forbidden line seems to be the formation of a large number of metastable atoms. Water vapor, if no free H_2 is present, is more efficient than N_2 in bringing atoms to the metastable level. This has been proved by measuring the absorption of the arc line 4046, which is absorbed only by the metastable atoms, and 0.005 mm. of H_2O vapor in the tube is sufficient to cause the reversal of 4046 if photographed with the large quartz Lummer-Gehrke plate, while 0.5 mm. of N_2 is necessary to do the same. G. G.

Polarization of light excited by electron impact. JOHN A. ELDRIDGE, ALEXANDER ELLETT AND HARRY F. OLSON. *Phys. Rev.* **29**, 207(1927).—The lines of the sharp subordinate series of the Hg spectrum, excited by a well-defined stream of slowly moving electrons, are in general weakly polarized; those of the diffuse subordinate series are quite strongly so. In this series the elec. vector of the excited light is perpendicular to the electron stream whenever $j = 0$ and parallel to the stream for lines involving a decrease of j. When j increases, the line is less strongly polarized and the results are not definite. The excited atoms are supposed to have their j vector in or near the plane perpendicular to the electron stream. Qualitatively the results for this series are in agreement with the concept that the atom emits a plane polarized or circularly polarized light quantum according as j remains const. or changes by one. This simple theory cannot be correct, however, as it leads to parallel polarization never greater than 33%, as contrasted to 60% observed for some lines; it also fails when applied to the somewhat weaker polarization of the other series. R. L. HERSHEY

Analysis of the first spark spectrum of sulfur (S^+). D. K. BHATTACHARYYA. *Nature* **122**, 241–2(1928).—The spectrum lines of S^+, observed by Lockyer in the constellation Rigel are probably due to the multiplets $^4P_3 - {}^4D_4$ and $^4P_3 - {}^4\bar{P}_3$ of the transition $2M_3N_1 \longleftarrow 2M_2N_2$ for the lines λ5454 and λ5033, and to the multiplets $^4\bar{D} - {}^4D$ and $^4P - {}^4\bar{P}$ of the transition $2M_2M_3 \longleftarrow 2M_2M_2$ for the groups at λ4142 – λ4174. H. F. JOHNSTONE

Polarization of infra-red radiation by calcite. A. M. TAYLOR. Cambridge. *Phil. Mag.* [7], **6**, 88–97(1928).—The expts. have shown that infra-red rays are partially polarized by transmission through thin plates of calcite cut parallel to the optic axis,

and such polarization effects have been used to det. which of the bands observed in the absorption spectrum of calcite really correspond to maxima of absorption, and which are merely spurious and due to interference effects. It is also suggested that the spectrum can be explained without assuming the inactive frequency to be active in combination (cf. *C. A.* **22**, 28). GEORGE GLOCKLER

The theory of light scattering liquids. Y. ROCARD. College de France, Paris. *Phil. Mag.* [7], **6**, 204–5(1928).—Priority claims against C. V. Raman and K. S. Krishman (cf. *C. A.* **20**, 1554; **22**, 2310). GEORGE GLOCKLER

Extreme ultra-violet spectra using large angles of incidence. J. BARTON HOAG. *Phys. Rev.* **29**, 208–9(1927).—A vacuum spectrograph was constructed with a concave speculum grating of 215.3 cm. radius and having 591 lines per mm. The Rowland mounting with the slit placed close to the grating, making the angle of incidence approx. 80°, was used. With C and Mg electrodes, spectra have been obtained from 220 A. U. to 1700 A. U. The scale varies from 3.54 A. U. per mm. at 1600 A. U. to 2.26 A. U. per mm. at 550 A. U. in the first order. R. L. HERSHEY

Excitation of spark spectrum of nitrogen. R. A. WOLFE AND O. S. DUFFENDACK. *Phys. Rev.* **29**, 209–10(1927).—The arc spectrum of N was excited in an interrupted low-voltage arc in a mixt. of He and N_2. Nearly all lines found by Merton and Pilley were verified; addnl. lines were found, some of which agree with those reported by Hardtke; others fill vacant spaces in multiplets computed by Kiess. The strength of the lines is due to a high degree of dissocn. of the N by excited He atoms present in large concn. R. L. HERSHEY

Critical potentials of spark lines of mercury. JOHN A. ELDRIDGE. *Phys. Rev.* **29**, 213(1927).—The intensities of 30 of the stronger spark lines of Hg have been measured as a function of voltage and 3 crit. values found less than 150 v. at 18, 24 and 57 v., resp. The abs. values are not certain as they may be changed by changing current d. R. L. HERSHEY

Ultra-violet radiations emitted by point discharges. JOHN THOMSON. Univ. of Glasgow. *Phil. Mag.* [7], **6**, 526–46(1928).—Preliminary expts. are described showing the variation with pressure of the ionizing and photoelec. radiations from H_2 and N_2 when the gases are excited by a discharge and the variation of the intensity of these radiations when the pressure is kept const. and the discharge current is varied. The curves obtained depend upon both absorption and emission variations, and an attempt is made to est. the relative importance of the 2 effects, and so to sep. them. Tentative explanations are offered of the various phenomena; it will be a matter for further investigation to decide between them. Reasons are put forward suggesting that the radiations are mol. in origin. A spontaneous ionization phenomenon in O_2 is described and an explanation is offered. GEORGE GLOCKLER

Resonance glow in a hydrogen-discharge tube. ROGERS D. RUSK. *Phys. Rev.* **29**, 213–4(1927).—At H_2 pressures below 0.2 mm. and potentials above the min. arcking potential a blue haze extends throughout the hot-filament discharge tube. Systematic variations of gas pressure, discharge potential, filament current and anode distance have been made to det. the nature of the glow. With fixed anode distance the glow appeared at a const. potential for pressures below 0.2 mm., at which pressure it became indistinguishable from the more common arc type of glow. The intensity of the glow and its extent are functions of gas pressure, anode distance and potential. Weakness of the Balmer lines and the effect of pressure change suggest a close relationship between the life of the excited mol. and its collision frequency. R. L. HERSHEY

New type of discharge in neon tubes. J. W. RYDE, L. JACOB AND B. S. GOSSLING. *Nature* **121**, 794(1928). H. G.

Anti-Stokes radiation of fluorescent liquids. R. W. WOOD. Johns Hopkins Univ. *Phil. Mag.* [7], **6**, 310–2(1928).—Exceptions to Stokes' law in the case of the fluorescing vapors of Na, I_2 and other elements are the rule. In the case of solns. of org. dyes it is less easy to show the phenomenon; in fact its existence was a matter of dispute for nearly a quarter of a century. So far no photographs have ever been published showing the presence of anti-Stokes radiations in the case of solns. In prepg. an article on fluorescence for the new edition of the Encyclopædia Britannica it appeared to be of interest to secure photographs establishing the reality of the phenomenon, and W. obtained such with ease. GEORGE GLOCKLER

Fluorescence of mercury vapor under low excitation. LORD RAYLEIGH. *Nature* **122**, 242(1928).—The energy required for the excitation of the green band fluorescence of Hg vapor is not as great as that of the Hg resonance line. On the contrary, it may be excited by the line λ3125 of Hg. The strong line λ3650, on the other hand, is unable to excite fluorescence. H. F. JOHNSTONE

Fluorescence spectra in metallic vapors excited by the light in the mercury arc. J. C. McLennan and I. Walerstein. *Phys. Rev.* **29**, 208(1927).—Fluorescence spectra were obtained from vapors of S, Se, Te and Bi at moderate temps. by using a Hg lamp as a source of excitation. S gave a set of bands extending over the range of the visible spectrum. Se at 325° gave a fluorescent spectrum ranging from 2200 A. U. to 6500 A. U.; at 425° it emitted a different spectrum of 9 broad bands between 4178 A. U. and 4829 A. U.; this latter spectrum disappeared at higher temps. Te gave a spectrum of regularly spaced bands in the visible region, the relative intensities of the bands varying with the pressure of the vapor. Bi gave a band spectrum between 4400 A. U. and 4900 A. U. The region of the Hg arc which excited the Te vapor to produce fluorescent radiation was between 2536 A. U and 3655 A. U. R. L. Hershey

Fluorescence and chemiluminescence of cod-liver oil. Jay W. Woodrow and G. M. Wissink. Iowa State College. *Phys. Rev.* **29**, 219(1927).—Cod-liver oil will produce a developable image on a photographic emulsion, an effect which is more pronounced if the oil has been exposed to ultra-violet light. A chemiluminescence is obtainable by oxidation of the treated vapor; the color is bluish green, but too faint for spectroscopic analysis. The fluorescent spectrum of cod-liver oil illuminated by the light from a quartz Hg-vapor arc has a max. intensity at a wave length of 5000 A. U. The color of the fluorescent light, as observed by the eye, appears to be the same as that produced by chemiluminescence. R. L. Hershey

Active nitrogen. C. N. Hinshelwood. *Nature* **122**, 404–7(1928).—A review. E. H.

Active nitrogen. Joseph Kaplan and Gunther Cario. *Nature* **121**, 906–7 (1928).—Metastable mols. of N are present in active N, but its long life cannot be explained on this hypothesis. Its behavior suggests that active N is at , and that metastable mols. are formed under the influence of the recombination of N atoms to mols. It is necessary also to assume the formation of metastable atoms under these conditions; these excite, by collisions of the second kind, the metastable mols. to the upper level of the first positive band. The metastable mols. appear to be quenched by heating, and the metastable atoms undisturbed. The absence of absorption in active N from 3000 A. U. to 6500 A. U. may be accounted for on this basis. W. T. R.

The afterglow in mixtures of nitrogen and oxygen. Bernard Lewis. Univ. of Minn. *Nature* **122**, 241(1928); cf. Kaplan, *C. A.* **22**, 2323, 2887.—Different types of afterglow may be excited in the same mixt. of N and O at the same pressure merely by altering the period of the discharge. At 0.53 mm. pressure in air, a $^1/_2$ sec. discharge gives rise to a blue afterglow, while an instantaneous discharge leaves a yellowish green afterglow. At a pressure where the transition from the yellowish green to the blue commences ($^1/_2$ sec. discharges being used) the former is displaced as a wave along the tubing leading from the discharge vessel while the latter glow occupies the vessel itself. H. F. Johnstone

Notes on active nitrogen. Arthur Edw. Ruark. Mellon Inst. *Phil. Mag.* [7], **6**, 335–6(1928).—Okubo and Hamada obtained certain spectra of metal vapors in active N_2 (*C. A.* **22**, 1730). R. compares his work (*C. A.* **21**, 1062) with theirs and discusses the discrepancies. George Glockler

The electrical conductivity of aqueous solutions of radon. Ellen Gleditsch and Liv Gleditsch. Inst. de Chim. de L'Univ. Oslo. *J. chim. phys.* **25**, 290–3(1928).—Small quantities of dissolved Rn, from 13.7×10^{-9} to 235×10^{-9} curies per cc., were found to have no influence on the cond. of the solns. E. G. VandenBosche

General theory of the photochemical reactions of the halogens. Jh. Cathala. *J. chim. phys.* **25**, 182–215(1928).—In all photochem. reactions of the halogens there is first a dissocn. of the mol. into neutral atoms. Thus for Cl_2 there is: $Cl_2 + h\nu = 2Cl$. Cl atoms may then unite with mols. to form chlorozone according to: $Cl + Cl_2 = Cl_3$. These reactions account for the rapid disappearance of Cl atoms in the gaseous phase. C. assumes the synthesis of phosgene to take place as follows: $Cl_3 + CO = COCl_2 + Cl$. The neg. catalytic effect of O_2 is due to the reaction: $Cl + O_2 = ClO_2$, which decreases the concn. of Cl_3. For the synthesis of HCl, C. assumes the reaction: $Cl_3 + H_2 = 2HCl + Cl$. In the formation of HBr ($Br_3 + H_2 = 2HBr + Br$) I_2 is a neg. catalyst by reason of the reaction: $Br_3 + I = BrI + Br_2$. On the other hand it is a pos. catalyst in the formation of HCl because of the formation of stable ICl, which reacts as follows: $ICl + Cl_2 = ICl_3$ and $ICl_3 + H_2 = ICl + 2HCl$. The catalytic effect of H_2O vapor in the synthesis of HCl is probably due to an electrostatic influence, drawing the mols. of H_2 and Cl_2 closer together, thus increasing the ease with which the electrons of the H_2 mol. can be sepd. On the other hand H_2O is not necessary for

the synthesis of $COCl_2$, since CO is already an "incomplete" mol. in a chem. sense.
E. G. VANDENBOSCHE

An interpretation of the chemical actions of radiation. P. VILLARD. *Compt. rend.* **186,** 1669–73(1928); cf. *C. A.* **22,** 1288.—Hypotheses of V. and Belliot (*C. A.* **22,** 921) on the antagonistic action of radiations on a photographic plate are presented and contrasted. The outstanding facts to explain are as follows: (1) Impressions produced by different frequencies (optical and x-rays) have not the same properties; (2) 2 images of high and low frequency may co-exist, and hence either one can be developed selectively; (3) in consequence of the independence of 2 impressions it is possible to solarize a plate to optical but not necessarily to x-ray frequencies. Plates fogged by high frequencies, *e. g.*, x-rays, can be restored to sensitivity to these same ν's by treatment with white light. Likewise the sensitivity of plates to violet light, previously destroyed by exposing to red light, may be restored. Such expts. indicate roughly the upper limit of the "regenerating" quantum necessary. V. supposes that at. levels assocd. with these reactions can be reconstituted by electronic agitation by wave lengths possessing quanta not quite large enough to draw from these levels the electrons which tend to return to them.
H. R. MOORE

Hydrogen activated by the electric discharge. A. DE HEMPTINNE. *Bull. sci. acad. roy. Belg.* **14,** 8–17(1928); cf. *C. A.* **22,** 2878.—H was subjected to a 400-v. d. c. discharge of 0.72×10^{-5} amp. and allowed to react with metallic oxides. The pressure was varied from 3.6 to 0.45 mm. of Hg. As the pressure is decreased the amt. of reduction increases. PbO_2 and HgO are rapidly reduced—PbO and CuO slowly. NiO is not reduced. The action is greater when the electrode nearer the oxide is neg. At const. pressure the amt. of PbO_2 reduced decreases with decreasing current and with the distance of the oxide from the electrode. This indicates that the action in this case is due largely to ions. Other expts. were made with the oxide in contact with one of the electrodes and with the use of a grid of the same polarity as the oxide. The ratio of the no. of H mols. which react to the no. of ions corresponding to the coulombs of electricity used was detd. The ratio is much greater when the grid is used than when it is disconnected. This is attributed to a preponderance of neutral H in the at., tri-at. or excited mol. state.
J. E. SNYDER

The influence of light on the color of ferric chloride solution. KENNETH S. RITCHIE. Stanford Univ. *J. Phys. Chem.* **32,** 1269–71(1928).—Exposure to intense radiation produces a photochem. change in the 3-component system H_2O–HCl–$FeCl_3$. The change is reversible and the solns. return slowly to their initial condition after the light is removed. Spectrocolorimeter measurements show that the absorption of light over various parts of the spectrum increases as the radiation is continued. The change is similar to that produced on heating the soln. and is probably due to hydrolysis.
R. E. GIBSON

X-ray coloration of kunzite and hiddenite. P. L. BAYLEY. Univ. of Rochester. *Phys. Rev.* **29,** 353(1927).—Absorption curves were obtained before and after exposure from 2000 to 300μ for pink kunzite and yellow green hiddenite. Kunzite had one weak wide absorption band at 540mμ. Bands were found for hiddenite at 1670, 1000, 630, 438, 432, 378 and 368mμ. X-ray treatment produced in hiddenite slight increase in absorption below 440mμ. Both minerals were colored very similarly—kunzite slightly more bluish green. In kunzite new brands occurred at 910 and 625mμ. Radiated kunzite showed no bands below 500mμ. It is suggested that the green color in both minerals is due to a similar physical cause.
L. D. R.

The Fermi-Dirac hypothesis of gas degeneration and its applications. E. S. BIELER. McGill Univ., Montreal. *J. Franklin Inst.* **206,** 65–82(1928). W. T. RICHARDS

Electric resistance of metals as a function of pressure. A. T. WATERMAN. Yale Univ. *Phys. Rev.* **29,** 368(1927).—That the pressure coeff. of resistance $(1/R)(dR/dP)$ is given by $(C/2) + (RT/2)\ (dx/dp + \delta v)$ is indicated from the influence of pressure on resistance, involving the effect of pressure on chem. equil. postulated between ions, atoms and electrons within the metal. C = compressibility, x = energy liberating electrons within the metal, δv = vol. change. The change in resistance due to pressure is due to a change in the mean potential energy of the free electrons. For elements in the same group, the rate of change with vol. of the mean potential energies of both the bound and free electrons is approx. a linear function of the at. no.

4—ELECTROCHEMISTRY

COLIN G. FINK

Electrochemical products emphasize interdependence of processes and industries. C. L. Mantell. *Chem. & Met. Eng.* **35**, 486–8(1928).—Electrochem. industries are divided into groups representing the electrolytic, the fused electrolyte and the electrothermic. Unit processes and the interdependence of electrochem. industries are featured. A discussion is included of conditions existing in industries mfg. Cl, Al, Al_2O_3, graphite, CaC_2, CS_2, P, steels, etc. Technology and its importance in future developments of electrochem. industries are stressed. A. D. Spillman

A home-made electric laboratory furnace. St. Reiner. *Chem.-Ztg.* **52**, 579 (1928).—The furnace is cheap and reliable with an upper temp. limit of about 2000°. It is made of fire brick; the dimensions are 60·26·38 cm. The bricks are cut out with a hammer to fit the 10 cm. diam. fireclay tube, the interstices being filled with fire brick cement. The tube in the heating room is completely covered by cryptol. The sheet metal lid is cut out to permit the passage of 2 C electrodes, which reach down into the cryptol material. A resistance of running water is used; the furnace consumes a max. of about 100 amp.; electrodes and cryptol have to be changed from time to time. R. D. Bumbacher

Power factor in high-frequency spark induction furnaces. R. Dufour. *J. Phys. Radium* [vi], **8**, 508–21(1927).—A study of the schematic function of the furnace is made based on certain hypotheses which enable a math. treatment of the subject to be developed from which the time of charge of the condensers, the number of charges per sec., the intensities of the current and heat liberated at the end of the charge or discharge, and eventually the power factors are calcd. successively. The variation of the power factor with the tension of the spark, and the relation of the no. of wave-trains per sec. to the phase-angle, are also derived. B. C. A.

Review of conditions leading up to electrolytic practice (zinc). H. R. Hanley. *Metal Ind.* (London) **33**, 135–6, 152(1928).—The essential factors making the electrolytic Zn process practical are: (1) improvement in grade of concentrate; (2) economic power; (3) dependable and economic methods of purification; and (4) organization. Characteristics of Tri-States concentrate are: (1) the Zn in the calcine is 97–8% sol. in dil. H_2SO_4; (2) there is only a trace of Fe in soln. and if As or Sb develops by repeated cycles some Fe would have to be added to the soln.; (3) the settling of the neutral pulp and the filtration of the acid mud are reasonably satisfactory; (4) the complete removal of Cd is standard practice; and (5) Co can be economically handled if necessary. General plant procedure is outlined. The acid balance of the process is realized when the acid generated in the cells is equal to that demanded by the calcine for the soln. of the ZnO in residues and purification products. Probably 3500–3600 kw.-hrs./ton (909 kg.) of bar Zn is a reasonable est. of all power, mech. and electrolytic. W. H. B.

Nature of the deposit formed during the electrolysis of neutral and alkaline solu-
tions with an antimony cathode. Julius Grant.   John Cass Tech. Inst. (London).
J. Chem. Soc. **1928**, 1987–8; cf. *C. A.* **19**, 2310; **21**, 1919.—A substance previously sup-
posed to be Sb_2H_2 is formed (1) by the electrolysis of NaOH (0.05–3*N*) solns., (2) by
the electrolysis of solns. contg. suspended metallic Sb or its compds. with a Pb cathode,
(3) by reduction of Sb compds. with nascent H. Conclusion: This substance is rather
metallic Sb in a finely divided state, contg. a small trace of adsorbed H. C. J. B.

The chromium facing of photo-engraved surfaces. E. A. Ollard. *Metal Ind.*
(London) **33**, 129–31(1928).—The principal points in the operation of a Cr-plating
soln. are outlined. The necessary plant consists of the generator, the vat and the
arrangements necessary for removal of fumes and regulation of temp. For facing
cylinders, it must be rotated in the vat at a speed (usually about 20 r. p. m.) permitting
a satisfactory deposit. It is probably best to treat half-tone plates and surfaces re-
quired to take the ink in cold soln. with dull deposit, while the photogravure cylinders
from the surface of which the ink is to be removed are best treated in warm soln. with
a bright deposit. The proportion of sulfate to CrO_3 is important. A good soln. for
face printing plates contains: 500 g. CrO_3/l., 7.5 g. castor sugar is added, the soln.
warmed, and the sugar added a little at a time to prevent undue frothing. The soln.

is boiled 1 hr. and allowed to cool. For a dull soln. 2 cc/1. of H_2SO_4 are added and for a bright soln. about twice as much. Pumice powder and a little cyanide are used for scouring half-tone plates, while vienna replaces pumice in bright finish surfaces. The total sulfate may be estd. by reducing a sample with EtOH in the presence of HCl and pptg. with $BaCl_2$. The sp. conductance being proportional to the degree of reduction can be used to det. whether the soln. has become over-reduced. Excessive sulfate may be eliminated by the addn. of $BaCrO_4$. Cr is harder than Ni, is not easily corrodible, adheres well to Cu, and has slight tendency to form pits. Cr may be stripped from Cu by immersion in dil. HCl permitting the removal of faulty or worn plates, and replating of the surface. W. H. BOYNTON

A lead-mercurous iodide voltaic cell. WARREN C. VOSBURGH. State Univ. of Iowa and Eppley Lab. *J. Am. Chem. Soc.* **50**, 2386–94(1928).—The following cells were measured at 25° and at 5° intervals between 20° and 40°: Pb(Hg) | PbI_2 + x *M*-KI | x *M* KI + PbI_2 + Hg_2I_2 | Hg. Pb(Hg) | PbI_2 + CdI_2 (satd.) | CdI_2 (satd.) + PbI_2 + Hg_2I_2 | Hg Cd(Hg) | CdI_2 (satd.) | CdI_2 (satd.) + Hg_2I_2 | Hg. The e. m. f. of the first 2 was found to be $E_t = 0.31748 + 0.000129 (t - 25)$ v. The e. m. f. of the third was found to be $E_t = 0.41702 + 0.000360 (t - 25)$ v. From the e. m. f. results the free energy and entropy changes and heats of reaction for the corresponding reactions were calcd From the latter and a reliable value for the heat of formation of PbI_2 the heats of formation of Hg_2I_2 and CdI_2 were calcd. to be 2 Hg (1) + I_2 (s) = Hg_2I_2 (s); $\Delta H_{25} = -28939$ cal. Cd (s) + I_2 (s) = CdI_2 (s); $\Delta H_{25} = -48918$ cal. E. R. SMITH

The photogalvanic cell furnished with silver iodide electrodes, and its application to photometry and illuminometry. SATOYASU IIMORI AND TOSHIMASA TAKEBE. *Sci. Papers, Inst. Phys. Chem. Research* **8**, 131–60(1928).—The cell studied consists of a glass trough coated on the outside with tin-foil, except for the cell-window through which light may pass, having a cover of cork or ebonite. The electrolyte is a soln. of KI and the electrodes, consisting of Ag plate whose surfaces are previously converted to AgI, are placed one behind the other at the back of the window. When the cell is exposed to light a reversible photochem. reaction characteristic of AgI occurs on the light side of the one electrode and the other remains unchanged, so that there is a photo-elec. e. m. f. between the two. The max. e. m. f. (π_m) attains a const. value after several min.; it varies with the concn. of the soln., temp. and size of the window. The rise of π_m on illumination is given by $\pi_m = a \log E - b$, where a and b are cell consts. and E is the luminous intensity. The cell can be used as a photometer or to record varying illuminations The sensitivity of the cell is low towards red light, better towards ultra-violet rays and is most effective for wave lengths between 400 and 500$\mu\mu$ for visible rays. E. G. VANDEN BOSCHE

The consecutive reactions entered into by the lead of the storage battery. WOLFGANG SEITH. Univ. Freiburg. *Z. Eletrochem.* **34**, 362–3(1928).—The course of the charge and discharge reactions in the lead storage battery have been followed in a cell contg. a pos. plate of ordinary Pb, with a neg. plate of radioactive Pb (Ra D). Th B was also used. The migration of the Pb ions was found by analyzing for the radioactive Pb. C. J. BROCKMAN

Production and application of high voltages in the laboratory. G. BREIT AND M. A. TUVE. *Nature* **121**, 535–6(1928).—A method of producing and measuring voltages up to 5 × 10^6 v. is described; high voltages are applied to vacua by the use of external electrodes. B. C. A.

Artificial daylight. J. W. T. WALSH. *J. Sci. Instr.* **5**, 81–8(1928).—The uses of artificial daylight and means for its production are discussed. Artificial daylight having the same spectral distribution as true daylight is distinguished from "sensation" daylight in which the same visual effect is produced by means of a different spectral distribution. The former only can be used for matching colors, while the latter is permissible for general illumination. The only practical method of producing artificial daylight is the subtractive method, in which the excess of red and yellow light is removed by an absorbing screen, or by reflection from a colored surface. Its production is therefore less efficient than that of ordinary artificial light. B. C. A.

Moisture in oils used in the electrotechnic industry. The approximate determination of their moisture content (MATTHIS) 22. Electrolytic Cr plating of glass molds and cylinder materials (ILLIO) 19. Metal protection in galvanizing technic (KRAUSE) 9. Removal of arsenic from H_2SO_4 (Russ. pat. 1514) 18. Metal coating (Can. pat. 283,034) 9. Improving cloth through a galvanic metallic precipitate (Ger. pat. 451,963) 25. Electric glass furnace (Norw. pat. 44,661) 19.

Storage battery. R. Bosch A.-G. Brit. 283,490, Jan. 11, 1927. Structural features.

Electric battery assembly. Berliner Batterie-Fabrik Ges. Brit. 283,856, Jan. 17, 1927. Structural features.

Seals for dry cells. Paul A. Marsal (to Can. National Carbon Co., Ltd.). Can. 282,684, Aug. 21, 1928. A seal for dry cells is obtained by applying a thin coating of nitrocellulose lacquers (as a soln. of pyroxylin in an ether-alc. mixt., or a soln. of an ether-sol. cellulose deriv. such as cellulose acetate or cellulose ethers in a suitable solvent) to the mix body of the cell, and an additional seal as rosin, sealing wax, pitch may then be applied if desired.

Electrolytic cells. Norsk Hydro-Elektrisk Kvaelstofaktieselskab. Norw. 43,571 and 43,572, Dec. 27, 1927. Cells for electrolytic processes particularly water decompn. are molded from a mass consisting of an asphalt compn. having a sp. gr. about equal to that of the electrolyte. Suitable compns. are (1) 990 kg. petroleum pitch m. above 130° + 10 kg. asbestos, (2) 670 kg. petroleum pitch + 330 kg. $BaSO_4$ powder, (3) 670 kg. petroleum pitch + 330 kg. $BaSO_4$ + 10 kg. asbestos fiber. The cell is assembled with electrodes and diaphragms which are kept in place by means of suitable diaphragms of a stiff material, for instance sheet metal, which are dissolved by a suitable chem. reagent, for instance the electrolyte itself, after the molding of the cell container has been accomplished.

Electrolyte for electric batteries. F. A. Macziossek (to Frigamin Ges.). Brit. 283,559, Jan. 14, 1927. An electrolyte for either wet or dry cell batteries, especially those of the Leclanche type, contains methylamine-HCl or other suitable hydrochloride of an org. amine. Org. acids such as cinnamic acid, sulfo acids or phenols or their suitable derivs. may be added to neutralize any hydroxides which may be formed. Acids which can be hydrogenated under the influence of a catalyst may be used and Hg can be used as a catalyst and to amalgamate the sol. electrode.

Barometric device for replenishing liquid in electrolytic cells. Walter E. Holland (to Philadelphia Storage Battery Co.). U. S. 1,684,276, Sept. 11. A device is specified suitable for use with storage batteries.

Recovering distilled water from gases produced in electrolytic cells. C. F. Holmboe. Norw. 44,685, Dec. 19, 1927. The gases, particularly H_2 and O_2 from H_2O decompn. cells, are passed through a condenser where the H_2O is recovered and afterwards through a washing app. where other impurities such as traces of alkalies, etc., from the electrolyte are removed by washing with cold water. The process is carried out under increased pressure.

Electrolytic rectifier. E. W. Engle (to Fansteel Products Co.). Brit. 283,208, Jan. 7, 1927. See U. S. 1,680,210 (*C A* **22**, 3591).

Electrolytic rectifier. M. E. MacGregor. Brit. 284,039, Nov. 4, 1926. The cathode of an electrolytic rectifier is made of "stainless" steel such as Cr steel and the electrolyte consists of citric acid or NH_4 citrate, to which ferrous, ferric or Al salts may be added, or of a mixt. of NH_4 Al phosphocitrate and ferrochromium oxalate. Various structural features are described.

Electrolytic rectifier. Soc. anon. pour l'exploitation des procédés E. Urbain (to Soc. Anon. des etablissements veuve P. Delafon et Cie). Brit. 283,953, Jan. 21, 1927. The acid electrolyte used as described in Brit. 272,921 (*C. A.* **22**, 1736) is replaced by an alk. or neutral soln. together with a Si-contg. electrode.

Elements for rectifiers of alternating current. J. Slepian (to Metropolitan-Vickers Electrical Co., Ltd.). Brit. 283,901, Jan. 19, 1927. Cu disks may be heated to between 500° and the m. p. of Cu in an oxidizing atm. until a layer of Cu_2O surrounded by a layer of CuO is formed on the metal. The disks may then be mounted in pairs on a cond. arbor in a bath contg. an electrolyte such as dil. H_2SO_4, NaOH, KF or NH_4-ClO_3 soln. with graphite electrodes on insulating collars between each pair of disks. Various other details are also given. Cf. *C. A.* **22**, 2518.

Chromium plating. Kevie W. Schwartz (to Chromium Products Corp. to Chromium Corp. of America, to United Chromium Incorporated). Can. 282,730, Aug. 21, 1928. Metallic Cr is deposited from a bath contg. 415 g. of commercial CrO_3, 12 g. commercial Cr $(OH)_3$, and 21 g of neutral commercial Cr sulfate per l. Electrolysis is performed with Cr, or Fe-Cr anodes at 40–45°; a voltage of 4.5 to 6 is satisfactory. The c. d. at the cathode ranges from 0.15 to 0.175 amp. per sq. cm.

Plating with chromium. John Merle Hosdowich (to The Metal and Thermit Corp., to Chromium Products Corp., to Chromium Corp. of America, to United Chromium, Inc.). Can. 282,540, Aug 14, 1928. An electrolytic bath contg. 325 g. of CrO_3 dissolved in the necessary vol. of H_2O is heated to boiling and into the hot soln. 12 g.

$Cr(OH)_3$ is stirred. Six g. $FeSO_4.7H_2O$ is added to the soln. The whole mixt. is dild. to 1 l. and is ready for electrolysis. The best temp. for electrolysis is between 35° and 45°; a suitable potential is 2.5 to 5 v. with current density of 0.05 to 0.2 amp. per sq. cm.

Aluminum. I. G. Farbenind. A.-G. Brit. 283,949, Jan. 21, 1927. In producing Al by electrolysis of a fused bath contg. alumina, the alumina is introduced in calcined form after having been treated to increase its d. by grinding under pressure as described in Brit. 272,109 (*C. A.* **22,** 1638).

Aluminum. Ture R. Haglund (to International Patent Corp.). Can. 283,424, Sept. 18, 1928. Al is produced from Al_2O_3 by electrolysis of a molten electrolyte contg. Al_2O_3, by supplying crystd. Al_2O_3 and amorphous Al_2O_3 to the electrolytic bath, the quantity of added amorphous Al_2O_3 amounting to about 10–40% of the total wt. of the added Al_2O_3.

Steel. Robert A. Hadfield. U. S. 1,683,886, Sept. 11. In order to produce flawless Ni-Cr steel low in S and P, molten refined base metal and materials such as Ni and ferro-chrome are heated in a basic elec. furnace in the presence of deoxidizing material such as C and ferro-Si and of suitable basic slag-forming material including lime, and the treated metal is afterward subjected to the action of a deoxidizing and refining slag to reduce the quantity of S and P in the metal to the desired limits.

Steel. Soc. anon. fonderia Milanese di acciaio. Brit. 283,489, Jan. 10, 1927. Molten cast iron prepd. in a cupola furnace by melting iron, steel or cast iron scrap is charged into an elec. furnace where it is mixed with Fe oxide and treated in the usual way. Two or more elec. furnaces may be used alternately.

Electrothermic production of zinc. Robert Lepsöe. Norw. 44,244, July 25, 1927. The reduction and distn. process is carried out in 2 sep. steps. As the first step a part of the charge is heated to the reaction temp. and the reduced and evapd. Zn is condensed in cooler parts of the charge while CO escapes. The second and final reduction and evapn. of the Zn is carried out in the same or in another elec. furnace.

Electrothermic production of zinc. F. Tharaldsen. Norw. 44,021, May 16, 1927. The temp. in the condenser is controlled by regulating the temp. of the liquid zinc bath in the condenser box, the most favorable temp. of the Zn bath being 470–530°.

Electrode for electrolysis of water. Nordiske Fabrikker De-No-Fa and C. F. Holmboe. Norw. 43,902, April 4, 1927. Structural features.

Self-burning electrodes. Det Norske Aktieselskab for Elektrokemisk Industri. Norw. 43,079, Dec. 27, 1927. The electrode is provided with inlays consisting of pieces of suitable form made from coal or graphite electrode mass and burned before the insertion. These inlay pieces are inserted in the girth of the electrode with projecting noses to which the elec. current contacts are connected, these connections being attached to inlay pieces which have the desired distance above the surface of the smelting bath.

Use of self-burning electrodes. Det Norske Aktieselskab for Elektrokemisk Industri. Norw. 44,673, Dec. 5, 1927. Mech. features of design and operation.

Distant manipulation of self-burning electrodes. Det Norske Aktieselskab for Elektrokemisk Industri. Norw. 44,461, Oct. 10, 1927. Mech. features.

Reducing the voltage loss in electrodes in metallurgical furnaces. Det Norske Aktieselskab for Elektrokemisk Industri. Norw. 44,736, Jan 9, 1928. Mech. and elec. features regarding the introduction of the elec. current into the electrode body.

Electric induction furnace. Hirsch, Kupfer- und Messingwerke A.-G. Brit. 283,886, Jan. 19, 1927. Structural features.

Electric induction pressure or vacuum furnace. Edwin F. Northrup (to Ajax Electrothermic Corp.). U. S. 1,683,986, Sept. 11.

Electrothermic furnace and process. Norsk Handels- og Industrilaboratorium A. S. Norw. 44,276, Aug. 1, 1927. A rotary cylindric furnace has several pairs of electrodes. The ends of some of them are covered, and of some not covered by the charge. In this way the heat is produced by resistance effect between the pairs of electrodes with the ends covered by the charge and by arc effect between the others.

Condenser for electrothermic zinc furnace. Aktieselskapet Malmindustri. Norw. 44,763, Jan. 16, 1928. The cross-sectional area of the condenser decreases in the direction of the moving of the zinc vapors in correspondence with the reduction of the vol. of the gas caused by the condensation. The cooling of the condenser is effected wholly or partially by steam.

Aluminum furnace. Peder E. Froland. Can. 282,967, Sept. 4, 1928. An elec. furnace having a particular form of carbon bottom and cathode connection is specified.

Dry reduction of iron ore in electric resistance furnaces. NORSK HYDRO-ELEKTRISK KVAELSTOFAKTIESELSKAB. Norw. 44,705, Jan. 2, 1928. The resistance elements, usually consisting of iron wire spirals, are protected against oxidation by introducing all or part of the fresh reduction gas into the furnace in such a way that the resistance elements are completely surrounded by such gas.

Carrying out chemical gas reactions in the electric arc. NORSK HYDRO-ELEKTRISK KVAELSTOFAKTIESELSKAB. Norw. 44,180, July 4, 1927. A long, stable, high-voltage arc burns in an elec. field which is independent of the working current, one electrode of the elec. field being the elec. arc itself and the other the surrounding pipe.

Treating hydrocarbons with the silent discharge. SIEMENS AND HALSKE A.-G. (Wilhelm Esmarch, inventor). Ger. 463,643, July 12, 1928. High-frequency a. c. (above 5000 cycles) is used in a water-cooled app.

Application of long, stable, high-voltage electric arcs. AKTIESELSKAPET NORSK STAAL. Norw. 43,971, May 2, 1927. An addn. to Norw. 43,570. (*C. A.* **21**, 2106.) A bath of molten metal is used for the hot electrode instead of a bath of fused refractory oxides. The metal bath is, however, covered with a relatively thin layer of fused refractory oxides or salts or a mixt. of such substances.

Compounds containing active oxygen. I. G. FARBENINDUSTRIE A.-G. (Erich Noack, Oswin Nitzschke and Georg Pfleiderer, inventors). German 463,794, July 19, 1928. Amalgamated cathodes in electrolytic prepn. of these compds. are renewed by wetting with Hg at short intervals or continuously or by electrolytic pptn. of Hg.

Removal of chlorine ions from metalliferous liquors or similar solutions. SIEMENS AND HALSKE A.-G. Ger. 452,088, Nov. 2, 1927. The purpose is to remove the chlorine ions from baths used for electrodeposition of metals. For example H_2SO_4 baths do not deteriorate Pb anodes when the circuit is broken but the Pb will deteriorate if Cl ions are present. This is accomplished by placing a Ag anode in the bath sepd. by a diaphragm so that the whole electrolyte streams through the diaphragm sepg. the anode chamber from the cathode chamber. A proportion of Ag corresponding to the Cl in the electrolyte is dissolved and forms AgCl, as a flocculent, easily filterable ppt. The liquor is filtered and reused.

Carbon filaments. ANTON LEDERER. Can. 282,800, Aug. 28, 1928. Carbon filaments for incandescent elec. lamps are manufd. by mixing substantially pure C in a finely divided state with a water-sol. salt contg. an oxide of iron (as ammonium iron nitrate, ammonium ferric sulfate and potassium ferric sulfate), heating and powdering the mixt., adding an oleic soap as a binder to form a plastic mass, squirting the plastic mass into filament form, and heating to at least 2500° in an atm. of substantially pure argon.

Thermionic filament cathodes. RADIOTECHNIQUE. Brit. 283,967, Jan. 21, 1927. Various structural details of filaments (which may have oxide coatings) are specified, which are suitable for use by direct heating with a. c. without "hum."

Filament for electric incandescent lamps. PATENT-TREUHAND-GES. FÜR ELEKTRISCHE GLÜHLAMPEN (to General Electric Co., Ltd.). Brit. 283,848, Jan. 17, 1927. Filaments of the closely wound type for high- power lamps are roughened over all or a part of their surface in such a manner that the black-body radiation so obtained is maintained during the useful life of the lamp. The roughening may be effected by sandblasting, or by chem. or electrolytic action. The filaments must be at least "several tenths of a mm." in diam.

5—PHOTOGRAPHY

C. E. K. MEES

A new photographic effect. FRITZ WEIGERT. *Naturwissenschaften* **16**, 613–4 (1928).—Clear AgCl-gelatin plates irradiated with linearly polarized light and physically developed give a dichroitic and doubly refractive silver deposit of optical axis parallel to the elec. vector of the light. The expts. were made with printing-out emulsions of Valenta type, thoroughly washed after prepn.; com. plates are too coarse-grained and allow depolarization. The effect is produced by white, blue or ultra-violet light. A very sensitive dichrometer method did not show any dichroism in a long-exposed, undeveloped sensitive film; the directly formed latent photosilver is therefore isotropic. It is thus evident that the customary theory of the photographic process, beginning with latent nuclei, may have to be revised. B. J. C. VAN DER HOEVEN

Collection of recipes for use in the photographic and reproduction arts. C. FLECK. *Sprechsaal* **61**, 163(1928).—Recipes are given for pickling solns. for different kinds of

metals, baths and lacquers for decalcomania, and other solns. and gelatins for use in these arts. R. A. HEINDL

Rate of desilverization of the wet collodion silver bath. B. P. O'SHAUGHNESSY. *Phot. J* 68, 123–7(1928).—Process workers use a hydrometer to measure the Ag content and thus the degree of exhaustion of their sensitizing bath. Check volumetric titrations show that the actual exhaustion after bathing many plates is not so great as that shown by the hydrometer. The differences in sp. gravities of the waste reaction products account for the discrepancy. K. C. D. HICKMAN

Peculiar reversal of the discharge figures on photographic plates. USABURO YOSHIDA AND JINZO TSUTSUMI *Mem. College Sci. Kyoto Imp. Univ.* 11, 267–70(1928).—A peculiar reversal of the discharge figures on photographic plates, which is caused by fogging the plate with a spark light simultaneously with the impression of the discharge figures, is described (cf. F. E. Nipher, *Trans. Acad. Sci. St. Louis* 10, 151–66(1900)). The wave length of the fogging light which is effective in this respect is shorter than about 420 mμ. This reversal is not caused by a simultaneous illumination of the photographic plates with two illuminations of short duration. E. P. WIGHTMAN

The study of traces of metal in paper. R. E. LIESEGANG. *Z. wiss. Mikroskop.* 45, 179–82(1928).—Paper for photographic purposes is tested for specks of Fe or bronze by coating first with the following reagent: 3 cc. alc. and 3 cc. 50% $AgNO_3$ soln., mixed and added to 400 cc. of a 2% collodion soln. This coating is allowed to dry a few hrs., and a second coating of 12% gelatin soln. is applied and dried thoroughly. On standing for a few days, local reduction of the $AgNO_3$ indicates the position of the metal specks. It is possible to strip the reagent coating from the paper, which may then be tested further. The method may be modified for testing emulsions on photographic papers. C. W. MASON

The light sensitivity of dyes. A. STEIGMANN. *Kolloid-Z.* 44, 326–9(1928); cf. *C. A.* 22, 2887.—A discussion is given of the effect on exposure of Ag halide grains produced by light-sensitive dyes. The hydrogenation theory of optical sensitizing is still very important. A method of hypersensitizing without NH_3 is given by which bathing in 0.5% $AgNO_3$ 2 min., then in a 3.0% NaCl bath and finally treatment with a pinachrome sensitizer is carried out. Such a pre-treatment of a coarse-grained negative emulsion optically sensitized with erythrosin also sensitizes. The sensitivity specks must act catalytically. NH_3 causes these specks to become more active. R. H. L.

Study of moving flames (PAYMAN) 24. Registering photodensitometer (HARRINGTON) 1. An interpretation of the chemical actions of radiation (VILLARD) 3.

Color photography. W. T. TARBIN. Brit. 283,765, Feb. 1, 1927. In exposing superposed layers sensitized for different colors simultaneously, the layer sensitive to the blue end of the spectrum is located during exposure farthest from the source of light and may comprise a high-speed bromide emulsion. The composite material may include stripping films and may, *e. g.*, be formed with a red-sensitive stripping layer on glass, a blue-sensitive layer on glass, and a green-sensitive non-stripping layer on thin celluloid enclosed between the layers supported by glass. Certain of the layers may be dyed to act as light filters, and various details are given.

Films for color photography. H. HORST (to Sirius Kleuren Film Maatschappij). Brit. 283,548, Jan. 13, 1927. The film consists of an emulsion layer, a carrier such as a celluloid compn. or the like, an opaque layer and a second emulsion layer, in the order named. The opaque layer may be colored with Mn peroxide or by a non-actinic dye sol. in the developing and fixing baths.

Color cinematography. R. GSCHÖPF. Brit. 283,560, Jan. 15, 1927. Negative records may be taken simultaneously on adjacent film strips one of which is sensitized for yellow-green with pinaflavol and the other for red with pinachrome-blue or pinacyanol-blue, in a camera with reflectors and a rotating multi-color filter, and these negatives are printed in register on opposite sides of a film sensitized on both sides and the images suitably dyed and mordanted by a method various details of which are described.

Photographic films embossed with lenticular elements on the side not coated with emulsion. G. CHRÉTIEN (to Soc. technique d'optique et de photographie). Brit. 283,954, Jan. 22, 1927. Mech. and optical features.

Photographic printing. RUDOLF FRITSCHE. Can. 283,344, Sept. 18, 1928. A soln. for treating wet blue-print paper to turn it green consists of $UO_2(NO_3)_2$ 1 oz., $K_3Fe(CN)_6$ 1 oz., AcOH 10 oz., H_2O 200 oz.

6—INORGANIC CHEMISTRY

A. R. MIDDLETON

Valency. IX. Molecular structure of thallium salts. (a) Thallium triiodide; (b) alkyl derivatives. ARTHUR J. BERRY, THOS. M. LOWRY, (MRS.) R. R. GOLDSTEIN AND F. L. GILBERT. Cambridge Univ. *J. Chem. Soc.* **1928**, 1748–68; cf. *C. A.* **22**, 1899.—TlI_3 was examd. in order to det. whether it should be regarded as thallic iodide or thallous polyiodide. Solns. in MeOH and acetonitrile form addn. compds. with pyridine and chloropyridines, and complex ions with KI, and exhibit the general reactions of a thallic salt, but the reactions of thallous ions could not be detected with certainty. The *absorption spectrum of TlI_3* in MeOH shows 2 maxima sepd. by 1400 A. U. while those of KI_3 are sepd by only 650 A. U. The spectrum is not that of a triodide ion, nor can the compd. be a simple aggregate of Tl^{+++} and I^-, since these ions are colorless and do not give rise to absorption bands. The iodide is, therefore, a tervalent compd., in which part of the halogen is linked directly to the metal. The mol. conductivities of Tl trihalides in MeOH and in acetonitrile are less than those of KI. The salts behave only as binary electrolytes, in which some of the halogen is linked to metal, even in the most dil. alc. solns. *Dimethylthallonium iodide* is hydrolyzed in dil. aq. solns. and is derived from a base much weaker than TlOH. The mol. cond. of *$TlBr_3$* is less than that of a binary electrolyte, except in dil. aq. solns. where it is hydrolyzed progressively. Hg and Tl are evidently related in the same way as C and N.

G. L. CLARK

The irreversible dehydration of some hydrated crystalline salts. A. RACOUSINE. *Bull. soc. chim.* **43**, 744–7(1928).—Borax, heated to 98°, quickly forms the stable pentahydrate, which on standing in the air absorbs but a small trace of H_2O. The monohydrate, formed by heating the salt to 200°, is likewise stable. The anhyd. salt, obtained by heating to 340°, absorbs H_2O somewhat more readily. Glauber's salt changes to the stable anhyd. salt after being exposed to the air for about 6 days and the process is not reversible. $Na_2CO_3.10H_2O$ changes to $Na_2CO_3.2H_2O$ in the air; the anhyd. salt is formed by heating it to 98°. On exposure to the air, the anhyd. salt forms the stable monohydrate.

E. H.

The chemistry of ruthenium. F. KRAUSS. *Z. angew. Chem.* **41**, 413–8(1928).—A review with bibliography of 93 references.

E. H.

Scandium and rare earths. P. B. SARKAR. *Ann. chim.* [x], **8**, 207–62(1927).—By a critical examn. of the data available in the literature and by the prepn. of a no. of new simple and complex salts of Sc an attempt is made to det. the analogies which exist between the compds. of this element and those of other tervalent elements, the Fe and the rare-earth groups, resp. From the point of view of the soly. of its salts Sc resembles in general the elements of the rare earths, but it also exhibits many close analogies with the Fe group in the cryst. form and compn. of many of its complex salts. Thus the acetylacetonates of Sc are isomorphous with those of Fe, and the double alkali sulfates with those of Al, while it forms a series of double alkali sulfates corresponding with the anhyd. alums which are quite unknown in the rare-earth series; its basic nitrates closely resemble those of Cr. Spectroscopic evidence obtained using a very pure sample purified by the sublimation of Sc acetylacetonate confirms its relationship with the Al family. No such intimate relationship is found. however, between the simple salts of Sc and those of either the rare-earth or Fe group of elements, Sc occupying a transitional position between the 2 groups. The following new salts of [illegible] $)_6.4H_2O$ of [illegible] H_4, Rb and [illegible]

sulfate, $Sc_2(SO_4)_3$, suggests that it is really Sc scandisulfate, $Sc[Sc(SO_4)_3]$; K Sc *selenate*, $KSc(SO_4)_2.2H_2O$; *basic nitrates* of compn. $Sc(OH)(NO_3)_2.3H_2O$ [erroneously described by Crookes (*C. A.* **2**, 2193) as the anhyd. normal nitrate], $Sc_2O(NO_3)_4.0.5H_2O$ (stable between 90° and 115°), and $Sc_4O_5(NO_3)_2$ (stable between 120° and 200°). $Sc(OH)_3$ forms a crimson lake with NH_4 aurintricarboxylate (Hammett and Sottery, *C. A.* **19**, 796), which, unlike the corresponding Al lake, is very sol. in $(NH_4)_2CO_3$ soln., the sensitivity of the test being of the order of 2.4×10^{-7} g.-atom of Sc per cc. (cf. Corey and Rogers, *C. A.* **21**, 870). A similar study of various new salts of Gd and Eu shows that these elements resemble both the Ce and Yt groups of the rare-earth elements and form a transition between the two groups. The following new salts of Gd are described:

formate; hydrogen tartrate $+2H_2O$; *normal tartrate* $+5H_2O$; *citrate* $+5H_2O$ and $+4H_2O$; *acetylacetonate* $+3H_2O$, m. 143.5–145°; nitrate $+6H_2O$, m. in sealed tube, 91° (not $6.5H_2O$, as described by Benedicks (*Z. anorg. allgem. Chem.* **22**, 393–421); *basic nitrate*, $3Gd_2O_3.4N_2O_5.3H_2O$; *antipyrine additive* compd. of the nitrate, $Gd(NO_3)_3.3C_{11}H_{12}ON_2$; *hexamethylenetetramine additive* compd. of the nitrate $Gd(NO_3)_3.2C_6H_{12}N_4.10H_2O$; *bromate* $+9H_2O$, m. 80°; *thiocyanate* $+7H_2O$; double *salt* with $Hg(CN)_2$, $Gd(SCN)_3.3HgCN_2.12H_2O$; *orthophosphate* $+5.5H_2O$; *iodate* $+5.5H_2O$; *perchlorate* $+8H_2O$; *periodate* $+4H_2O$; *chlorate* $+10H_2O$; *double K oxalate*, $K_2C_2O_4.KGd(C_2O_4)_2.4H_2O$; *double carbonates* of the type $M_2CO_3.Gd_2(CO_3)_3.nH_2O$ of *K* $+12H_2O$, NH_4 $+4H_2O$, and Na $+13H_2O$; salts with *K ferrocyanide*, $KGdFe(CN)_6.5H_2O$; *ferricyanide* $+4.5H_2O$; *sulfite* $+12H_2O$ and $+11H_2O$; *double K chromates*, $K_2CrO_4.Gd_2(CrO_4)_3.7H_2O$ and $5K_2CrO_4.2Gd_2(CrO_4)_3.10H_2O$. The following new salts of Eu are described: *oxalate* $+10H_2O$ and $+5H_2O$; *nitrate* $+6H_2O$, m. in sealed tube, 85°; *citrate* $+5H_2O$; *hydrogen tartrate* $+2H_2O$; normal *tartrate* $+5H_2O$; *acetylacetonate* $+3H_2O$, m. 136–137°; *acetate* $+4H_2O$ and $+3H_2O$; *iodate* $+5.5H_2O$; *cyanoplatinates* $+21H_2O$, $+18H_2O$, and $+H_2O$; *carbonate* $+3H_2O$; *double K oxalate* $+2H_2O$; *orthophosphate* $+4H_2O$. B. C. A.

Pseudo-ternary systems containing sulfur. III. The system sulfur–sulfur monochloride. Dalziel L. Hammick and Michael Zvegintzov. Oxford Univ. *J. Chem. Soc.* **1928**, 1785–91; cf. *C. A.* **21**, 2089.—Discordant views are held as to the possibility of subchloride formation in $S\text{-}S_2Cl_2$ mixts. H. and Z. seek direct phase-rule evidence from a detailed study of solid-liquid equilibria, and det. the *soly. curve of S in* S_2Cl_2 under conditions favoring only S and also the temps. at which these solns. are in equil. with solid after having been heated to various temps. until internal equil. has been reached and then chilled. A new compd., S_4Cl_2, seems to be clearly established. G. L. Clark

The action of nitrogen on manganese. G. Valensi. *Compt. rend.* **187**, 376–8 (1928).—Pyrophoric Mn, obtained by distn. of its amalgam, absorbs, when heated in pure N at 760 mm., amts. of N which are a function of the temp. They decrease from 15.5 g. N per 100 g Mn at 390° to 6 g. at 1030°. This explains the no. of formulas of nitrides of Mn so far proposed—Mn_3N_2, Mn_5N_2 and Mn_7N_2. The dissociation of the product richest in N was studied at diff. temps. The system of isotherms obtained is in some respects very like the Cr-N system previously studied by V. (*C. A.* **22**, 3817). The curves represent either solns. of N in Mn or, rather, solns. of a nitride. The true formula of the nitride is still unknown, but it is richer in N than is Mn_3N_2. Higher pressures would be necessary for its prepn.; up to 1.5 atm. V. obtained no positive results. Louise Kelley

The oxidation of ferrous hydroxides in air. Alfons Krause. Univ. Posen. *Z. anorg. allgem. Chem.* **174**, 145–60(1928).—Solns. of $FeSO_4.7H_2O$ are pptd. with NaOH, the quantity of NaOH being varied so that the ratio $FeSO_4/NaOH$ ranges from 1/0.25 to 1/8. The ppt. is filtered, washed free of SO_4 and allowed to dry and oxidize in the air. Detn. of Fe^{++} and Fe^{+++} in the dry residue shows that the oxidation of $Fe(OH)_2$ is dependent upon $[H^+]$ in the soln. from which it is pptd. With the ratio $FeSO_4/NaOH$ equal to 1 or more, complete oxidation to ferric oxide hydrate occurs, while when this ratio is less than 1, the final oxidation product always contains Fe^{++}. The relation of FeO/Fe_2O_3 in the product, however, never exceeds $\frac{0.3}{1.0}$. As the quantity of Fe^{++} increases the color of the oxidized mass changes gradually from yellow to nearly black. Detns. of p_H showed that where this is 5.2 or less in the soln. from which $Fe(OH)_2$ is pptd., the final oxidation product is the positively charged meta-Fe_2O_3.aq. If the acidity is increased to $p_H = 3.5$, a ppt. is thrown down which oxidizes in the air to a compd. contg. SO_3 in which the ratio $Fe_2O_3/SO_3 = 3.57/1.0$, while if the acidity is increased to $p_H = 0.3$, $FeSO_4$ crystallizes from this soln. and no oxidation occurs. If $MgSO_4$ is added to the soln. of $FeSO_4$ in the proportion of 1:1, the ppt. on oxidation is found to be magnesium ferrite, Mg having entirely displaced Fe. The brown ortho-Fe_2O_3.aq. (isoelec. point $p_H = 7.7$) is less stable than the meta-compd., gradually changing to the meta-compd. under H_2O. The meta-compd. peptizes in dil. AcOH as well as in dil. NH_4OH, and is insol. in glacial AcOH, in which the ortho-compd. is sol. The existence of 2 series of ferric oxides or oxide hydrates, crystallographically different, is indicated. H. S.

The composition and behavior of ferric sulfide. F. Feigl and E. Backer. Univ. Wien. *Z. anal. Chem.* **74**, 393–8(1928).—For a long time the existence of Fe_2S_3 was doubted and although its existence is admitted today it is a fact that its chem. behavior is somewhat anomalous. Sometimes it reacts as if FeS were present and the explanation that this is due to the reducing power of H_2S when an acid is added is not altogether

satisfactory. Thus when neutral $HgCl_2$ in satd. NaCl soln. is treated with Fe_2S_3, HgS is formed and the soln. contains Fe^{++} whereas with $Zn(OH)_2$, ZnS and $Fe(OH)_3$ are obtained. Moreover, when Fe_2S_3 is formed by adding $(NH_4)_2S$ to $Fe(OH)_3$ the ppt. appears to be Fe_2S_3 whereas when it is formed by adding $(NH_4)_2S$ to an ammoniacal tartrate soln contg. tervalent Fe, the ppt. is $Fe_2S_3.(NH_4)_2S$. The explanation for these differences is not yet clear. W. T. H.

The preparation and properties of pure phosphorus trioxide. CHRISTINA C. MILLER. Univ. of Edinburgh. *J. Chem Soc.* **1928**, 1847-62.—A study of the rate of absorption of O by P_2O_3 in the presence of water vapor at various pressures indicates that the luminescence of the oxide is connected with the presence of dissolved P. When prepd. by Thorpe and Tutton's method P_2O_3 always contains P, which may be removed by low-temp. recrystns. from CS_2 followed by exposure to light and volatilization. The pure oxide melts at 23.8°, or 1.4° higher than the unpurified product, and it does not glow nor oxidize in moist or dry O_2 as it does if P is again added. The P_2O_3 dissolves 1.7 g. P per 100 g. at 25°. G. L. CLARK

Cyanogen compounds of the platinum metals. III. Cyanogen compounds of osmium. F. KRAUSS AND G. SCHRADER. Braunschweig Tech. Hochschule. *J. prakt. Chem.* **119**, 279-86(1928); cf *C. A.* **22**, 3367.—The compd., $K_4[Os(CN)_6].3H_2O$, (I) is prepd. by interaction of KCN and K osmiate. It is white, cryst., sol. in H_2O, and is a deriv. of bivalent Os. Characteristic ppts. are formed with heavy metal ions. $Cu_2[Os(CN)_6].xH_2O$ (II) is formed by action of $CuSO_4$ soln. upon I, and is a flocculent, yellowish brown ppt., which cannot be dehydrated without decompn If II is dissolved in concd. NH_4OH and evapd., a dark green microcryst. powder is formed, $Cu_2[Os(CN)_6].4NH_3$. It is stable in the air and is quite similar to the corresponding Ru salt. $Ni_2[Os(CN)_6].xH_2O$ is prepd. in a similar manner to the Cu salt. It is bright blue, unattacked by acids and nearly so by alkalies. With NH_4OH it forms the compd., $Ni_2[Os(CN)_6].6NH_3$, cryst., violet blue in color. It slowly loses NH_3 in the air. If the free acid is prepd from I, and a soln. of strychnine phosphate added drop by drop until no more ppt. is formed, the compd. on filtering, washing and drying gives small white crystals of the compn., $[C_{21}H_{22}O_2N_2H_2][H_2Os(CN)_6]$. An Os cyanide of the first order is not obtained nor is it possible to prep. by oxidation double cyanides with a higher valency than 2. H. STOERTZ

Investigations on silicates. E. CHERBULIEZ AND P. ROSENBERG. Univ. de Genève. *Helv. Chim. Acta* **11**, 731-50(1928).—A study of the cond. will detect and record the reactions taking place in the silicates at high temp. Silicates of the orthoclase or leucite types begin to dissociate at about 800°, *i. e.*, below their m. p.; SiO_2 is formed, together with a silicate poor in silica, probably of the nephelite type. This reaction is detected by an increase of the cond. at const. temp.; it is monomol. and reversible. An equil. exists between silicates of the orthoclase, albite, leucite type on the one side and SiO_2 + a silicate of the nephelite type on the other side. An increase of the temp. favors this second phase. It has been exptly found that a mixt. of nephelite and quartz heated at 900-1000° presents a decrease of its cond. at const. temp. This proves that the mixt. is reacting in the opposite direction, forming a silicate of the orthoclase type. A. L. HENNE

Constitution of the silicates. W. WAHL. *Z. Krist.* **66**, 33-72(1927).—Structural formulas are derived for complex alkali aluminosilicates having an equal no. of Al and alkali metal atoms on the assumption of a complex univalent anion of which the central Al atom is quadrivalent. More complex anions are formed by the union of SiO_3 or Si_2O_5 groups In those compds. having a fewer no. of Al than alkali atoms certain of the former are regarded as sexavalent, the complex anions being then tervalent. Similar types of formulas are proposed for the alk. earth aluminosilicates. Compds. contg. H are in many cases regarded as acid salts, and their formulas are derived on this principle and on those given above. *Ibid* 173-90.—The structure of the additive compds. formed between aluminosilicates and inorg. salts is discussed. Natural non-aluminiferous silicates are regarded as salts of complex anions contg. sexavalent Si; more complex types of anions are produced by the linking of SiO_3 groups by O chains. Minerals of the pyroxene, amphibole and mellilite groups are formulated on the hypothesis of bridge formation by SiO_3 groups and O atoms. The structure and mode of polymerization of the complex silicates are surveyed in the light of their infra-red absorption spectra. B. C. A.

Constitution of aluminosilicates, conditions of their formation, and transformation in soil. W. WAHL. *Finska Kemistsamfundets Medd.* **36**, 22-61(1927); cf. preceding abstract.—In those silicates which are formed at high temps. Al has a coördination no. 4, while for those formed at low temps. it tends to be 6. Formulas with 2 Al atoms

are improbable; in the cryst. state the aluminosilicates are highly polymerized. The
reactions leading to the formation of minerals in the magma consist of (*a*) dehydration
processes and (*b*) additive reactions; the effect of these processes is traced in the for-
mation of hornblende and muscovite. The formation of biotite is summarized as follows:
(i) $6K[Al^{IV}O(SiO_3)] + 12H_2O = K_6H_{12}[Al_6^{VI}O_6(OH)_{12}(SiO_3)_6]$, (ii) $6Mg_2SiO_4 + 12H_2O$
$= 6MgSiO_2(OH)_2 + 6Mg(OH)_2$, (iii) $K_6H_{12}[Al_6^{VI}O_6(OH)_{12}(SiO_3)_6] + 6MgSiO_2(OH)_2 =$
$K_6H_{12}[Al_6^{VI}O_6(SiO_3)_6(MgSiO_4)_6] + 12H_2O$, (iv) $(K,H)_6H_{12}[Al_6^{VI}O_6(SiO_3)_6(MgSiO_4)_6] +$
$6Mg(OH)_2 = (K\,H)_6Mg_6[Al_6^{VI}O_6(SiO_3)_6(MgSiO_4)_6] + 12H_2O$. B. C. A.

A study of uranyl sulfate. A. Colani. *Bull. soc. chim.* **43**, 754–62(1928).—
By crystg. UO_2SO_4 from mixts. of H_2O and H_2SO_4 at 25° a no. of salts were obtained,
the formation of which was essentially dependent on the concn. of H_2SO_4. The solid
phases were dried *in vacuo* and weighed. The following compds. were found: UO_2SO_4.-
$3H_2O$, $UO_2SO_4.2H_2O$, $(UO_2SO_4)_2.H_2SO_4.5H_2O$, $UO_2SO_4.H_2SO_4.2H_2O$ and $UO_2SO_4.H_2SO_4$.-
$0.5H_2O$. The systems $UO_2SO_4.H_2O$ and $(NH_4)_2SO_4$, K_2SO_4 and Na_2SO_4 were likewise
studied at 25°. E. G. VandenBosche

Higher polythionates. A. Kurtenacker and A. Czernotzky. Tech. Hoch-
schule, Brünn. *Z. anorg. allgem. Chem.* **174**, 179–88(1928).—If 75–200 cc. of cold concd.
HCl is added to a soln. of 125 g. $Na_2S_2O_3$ in 130–150 cc. H_2O to which has also been
added 8–20 cc. of *N* Na_2HAsO_3, polythionates are formed. If the av. S content *n* of
the polythionates formed, $S_nO_6^{++}$, is detd by the sulfite and cyanide methods, it is
seen that the higher the HCl concn. the greater is *n*. Relatively pure pentathionate
is obtained when the ratio $\frac{\text{mol. HCl}}{\text{mol. } S_2O_3}$ is equal to 1.8. If this ratio is about 5, then about
equal parts of pentathionate and hexathionate are formed. If the solns. obtained
are concd. the value of *n* rises. The mechanics of the formation of higher polythionates
from lower ones is as follows: $S_5O_6^{++} + S_2O_3^{++} + H^+ \rightleftharpoons S_6O_6 + SO_3H$. If the acid
concn. is low, this equil. tends to go to the left while if it is high it goes to the right.
Raschig's Na_2CO_3 method for pentathionate detn. is rejected, as only a fraction of the
S_5O_6 is decompd. according to the equation $S_5O_6 = S + S_4O_6$. S_4O_6 is decompd. in alk.
soln. H. Stoertz

Sodium ethylene thiosulfate, $Na_2C_2H_4S_4O_6$. O. Yu. Magidson and V. M. Krol.
Trans. sci. chem. pharm. inst. (Moscow) **6**, 21–8(1923).—When ethylene dibromide
and satd. aq. Na thiosulfate are stirred for 10–15 days at 40°, plates of *Na ethylene
thiosulfate*, $Na_2C_2H_4S_4O_6$, decompg. when heated, are obtained. B. C. A.

Mercuri-tetrammine persulfate. Fr. Fichter and Salomon Stern. Anstalt
für anorg. Chemie, Basel. *Helv. Chim. Acta* **11**, 754–8(1928).—Criticism of N. Tarugi
(*Gazz. chim. ital.* **33**, 127(1903)) and Gmelin-Kraut-Friedheim (*Handbuch der anorg.
Chemie* V, II, 613–4). The salt described as $Hg^INH_4S_2O_8 + 2NH_3$ is really a Hg^{II}
compd. A const. wt. of NH_3 is obtained only after drying in an NH_3 atm. The true
formula is $[Hg(NH_3)_4]S_2O_8$. The hydrolysis gives a mixt. of basic salts, with no definite
compn., but no salt of the $HgNH_4SO_5$ type. A. L. Henne

**Hexamino- and pentaminoaquo complex salts of tervalent cobalt and chromium
crystallizing in the cubic system.** O. Hassel and G. Bödtker Naess. Univ. of Oslo.
Z. anorg. allgem. Chem. **174**, 24–30(1928).—The following compds. are prepd. by methods
already described: $[Co(NH_3)_6]SO_4I$ (I), $[Co(NH_3)_5H_2O]SO_4I$ (II), $[Co(NH_3)_6]SO_4Br$
(III) and $[Co(NH_3)_5H_2O]SO_4Br$ (IV). Optical investigation indicates strong anomalous
double refraction for the luteobromide sulfate, the other prepns. being optically isotropic.
X-ray examn. shows a face-centered cubic translation group leading to a structure like
that of *fluorspar* in which the Ca has been replaced by the complex cation, one F by the
SO_4 group and the other by Br or I. The 2 iodide sulfates are identical as are also the
bromide sulfates. This is confirmed by analysis. $[Co(NH_3)_6]SeO_4I$ (V) is prepd. in
the same manner as I except that $(NH_4)_2SeO_4$ is used in place of the sulfate. In appear-
ance this cannot be distinguished from I, but its Debye diagram gives a somewhat
higher lattice const. The bromide selenate is prepd. by adding dil. H_2SeO_4 to a warm
soln. of III. It seps. as long tetragonal prisms and optically shows rhombic symmetry.
By pptn. of a soln. of $[Co(NH_3)_6]Br_3$ with a soln. of $(NH_4)_2CrO_4$ fine needles of quadratic
cross section sep.; they have the formula $[Co(NH_3)_6]CrO_4Br.3H_2O$. They are identical
with the corresponding selenate and sulfate. $Co(NH_3)_6CrO_4I$ is prepd. by treating
$CoCO_3$ with an excess of H_2CrO_4, followed by neutralization with NH_4OH after CO_2
has been evolved, and subsequent treatment with I. An analogous series can be prepd.
from this compd. by using the other halogens or replacing Co with Cr. The cubic
structure is always obtained. In an effort to prep. analogous Mo compds. $CoCO_3$
and MoO_3 are digested with H_2O until all CO_2 is driven off, concd. NH_4OH and I are
added and the digestion is continued for 1 hr. It is filtered hot, a red compd. being

left on the filter which on analysis is found to be $2[Co(NH_3)_6]_2(MoO_4)_3.3H_2O$. On cooling the filtrate a golden brown, very sol. cryst. compd. seps., $Co(NH_3)_6MoO_4I$. The crystals, however, are not cubic and give an x-ray diagram different from the analogous SO_4 and SeO_4 compds. Failure to obtain the fluorspar structure is explained as due to the magnitude of the MoO_4 ion. The perchlorates, $[Co(NH_3)_6](ClO_4)_3$ (VI), $[Co(NH_3)_5H_2O](ClO_4)_3$ (VII), $[Cr(NH_3)_6](ClO_4)_3$ (VIII) and $[Cr(NH_3)_5H_2O](ClO_4)_3$ (IX) are prepd. All show symmetrical cubic crystal structure. VII is deep red in color, VIII yellow and IX bright red. VI is prepd. by action of $HClO_4$ upon the corresponding chloride followed by crystn. VII and IX are prepd. by action of moist Ag_2O upon $[Co(NH_3)_5Cl]Cl_2$ (X) or the corresponding Cr compd., followed by neutralization of the base with $HClO_4$. VIII is prepd. by action of $HClO_4$ upon the corresponding nitrate. $[Co(NH_3)_5H_2O]SO_4ClO_3$ is prepd. by action of Ag_2O upon X followed by neutralization of the sol. base thus formed with a soln. of $HClO_3$ contg. H_2SO_4. Beautifully formed, optically isotropic octahedrons sep. from soln. on evapn. They give all the reactions of the chlorates. This compd. shows the characteristic fluorspar structure. The length of the cubic edge of a few of these compds. is given as follows: I —10.71 A. U., II —10.62 A. U., III —10.51 A. U., IV —10.45 A. U., V —10.79 A. U., $[Co(NH_3)_6]SeO_4Br$ —10.63 A. U., $[Co(NH_3)_5H_2O]I_3$ —10.81 A. U., VI —11.38 A. U., VII —11.32 A. U. H. Stoertz

Reactions in the solid condition at high temperatures (Jander) 2.

7—ANALYTICAL CHEMISTRY

W. T. HALL

Method of evaluation of analyses. I. O. Liesche. *Z. angew. Chem.* **41**, 748-50 (1928).—A systematic method is described for the calcn. of the compn. of a complicated mixt. as regards the actual simple, double or complex salts present, from the usual analytical data giving the percentages of anions and cations or basic and acidic oxides. Examples of the application of the method to analyses of ultra-marine and of a hard water are given. B. C. A.

Sampling of materials. I. General principles involved. W. R. D. Jones. *Metal Ind.* (*London*) **32**, 585-8(1928). **II. Gases and liquids.** *Ibid* 609-12. **III. Sampling of water, oil, slimes and powdered substances.** *Ibid* **33**, 3-4. **IV. Sampling of coal.** *Ibid* 27-8. **V. Sampling of ores and concentrates.** *Ibid* 125-8. **VI. Sampling of ores, metals and alloys.** *Ibid* 199-203.—An account of methods in use in various parts of the world. W. T. Hall

Sampling of granular materials. Bernhard Baule and A. Benedetti-Pichler. *Z. anal. Chem.* **74**, 442-56(1928).—By means of the laws of probability, equations are developed showing how the errors due to sampling can be computed. From these it is easy to find what wt. of sample should be taken for analysis. This is illustrated by practical examples. The application of micro-methods to the analysis of mixts. is also discussed and the formulas of Mika (*C. A.* **22**, 1926) are shown to hold true only for a special case. The original paper must be consulted for details. W. T. H.

Chemical analysis by x-rays. A. H. Turner *Chem. Eng. Mining Rev.* **20**, 361-3(1928).—A brief account of some work done with C. E. Eddy and Laby on the detection and detn. of Cu, Fe, Ge, Co, Ni, As, Pb and Bi. It is possible to detect as little as 0.0001% of these elements existing as impurities; the no. of elements which can be detected in this way is large; the method is rapid and but very little material is required to make the x-ray target. W. T. H.

Volumetric micro-analysis and centrifugo-volumetry. Robert F. Le Guyon. *Ann. chim.* **10**, 50-112(1928).—In connection with some studies on the elimination of H_3PO_4 it was necessary to analyze small quantities of urine obtained with the catheter and this led to the development of a micro-analytical method. In this present paper, to which a bibliography of some 66 papers is appended, volumetric methods applicable to the detn. of small quantities of substances are discussed. In Part I, some relatively new volumetric pptn. reactions are mentioned and their application to micro-analysis is shown. The detn. of PO_4^{---} with Ag^+ and other precipitants is discussed thoroughly; the titration of Ba^{++} with CrO_4^{--} and CrO_4^{--} titrations of Hg^{++}, Pb^{++} and Ag^+ are described. In Part II, reactions of Cl^-, SO_4^{--}, PO_4^{---}, AsO_4^{---}, CO_3^{--}, CrO_4^{--}, CNS^-, Ag^+, Pb^{++}, Hg^{++}, As^{+++}, Sb^{+++}, Sn^{++}, Bi^{+++}, Cu^{++}, Cd^{++}, Fe^{++}, Fe^{+++}, Cr^{+++}, Mn^{++}, Zn^{++}, Al^{+++}, Ba^{++}, Sr^{++} and Mg^{++} are discussed from the stand-

point of "centrifugo-volumetric methods" *i. e.*, reactions in which the persistence of color in the soln. titrated is taken as the end point and a colored ppt. is removed from the soln. quickly with the aid of the centrifuge. W. T. H.

Solubility influences and quantitative analysis. I. E. WENDEHORST. *Z. angew. Chem.* **41**, 567–8(1928).—The fact that the normally negligible solubilities of certain substances are often not inconsiderable in presence of neutral salts is responsible for a number of errors in gravimetric detns. Expts. in which known quantities of Zn and Cd were pptd. by Na_2CO_3 and $(NH_4)_2CO_3$, resp., from media contg. varying amts. of Na, K or NH_4 salts show that under these conditions the amt. of oxide finally weighed may be slightly greater, or considerably less, than the theoretical amount. B. C. A.

Nephelometric analysis using a spectrophotometer. K. JABLCZYN'SKI AND W. STANKIEWICZ. *Roczniki Chem.* **7**, 534–48(1927).—The least errors: 0.79, 1.50 and 0.53% are obtained with orange, yellow and green light, resp. The errors for red and blue light are: 2.35 and 1.98%. High angles, about 76°, give the smallest errors. $K = (\ln \lg \alpha - \ln \lg \alpha_0)/c$, where α_0 and α are the rotations with clear water and the solns. examd. and c is the concn. Expts. with $BaCl_2 + H_2SO_4$ without a protective colloid showed that K increases with the speed of stirring (*I*), the H_2SO_4 concn. (*II*) and inversely with the $BaCl_2$ (*III*). The effects of *II* and *III* are very marked. K is higher when $BaCl_2$ is poured into H_2SO_4 than when the reverse is the case. In 0.25% gelatin the effect of *I* was insignificant; *II* and *III* were still definite. One % gum arabic almost doubled K but made it independent of *I* and *II*. *III* and *IV* had a similar effect as in the absence of gum arabic With $CaCl_2 + K_2C_2O_4$ similar results were obtained. For the study of amorphous ppts. $FeCl_3$ and $AlCl_3$ were pptd., with NH_3, $CuCl_2$ and $NiCl_2$ with NaOH *Fe(OH)₃*.— In the presence of excess NH_3, *I* has little effect. K increases with the NH_3 concn. to a certain NH_3 excess, beyond which it is no longer affected K decreases very slowly with the $FeCl_3$ concn. The error is 0.2 and 6.2%. $Al(OH)_3$.—K decreases with increasing NH_3 concn. probably because of the soly. In the presence of 20% NH_4Cl the pptn. is quant. from hot (not from cold) solns. K decreases with the Al concn. Error.—1.7% without, 0.5% with NH_4Cl. Conclusion: The present nephelometric methods are entirely inadequate. Spectrophotometry with an improved technic will replace gravimetric analysis in industry. MARY JACOBSEN

Colorimetric analysis using a spectrophotometer. K. JABLCZY'NSKI AND W. STANKIEWICZ. *Roczniki Chem.* **7**, 549–58(1927).—The method and equation are the same as thos applied in the nephelometric detns. (cf. preceding abstr.). In the reaction: $FeCl_3 + 3NH_4CNS = Fe(CNS)_3 + 3NH_4Cl$, K increased rapidly with the NH_4CNS concn. even when the relation Fe:CNS reached 1:96. The hypothetical compd., $(NH_4)_9Fe(CNS)_{12}$ therefore, does not exist. The HCl concn. does not affect K when Fe:HCl = 1:6. Higher concns. lower K, the decrease being 20% for Fe:HCl = 1:512. K is also insignificantly lowered by a decrease in Fe concn. In the reaction: $CuCl_2 + 4NH_4OH = [Cu(NH_3)_4]Cl_2 + 4H_2O$ Beer's law is valid, provided the NH_3 concn. remains const. The Cu concn. has no effect on K; a 16-fold increase of the NH_3 concn. increases it by 20%. The error is 0.21%. *Fehling's soln.*—K increases slightly with the $C_4H_4O_6$ concn. up to $Cu:C_4H_4O_6$ = 1:4 and remains const. from this point on. A moderate rise of K is caused by a decrease of the Cu concn., a very marked one by an increase of the NaOH concn. The error is 0.7% for an angle of 80–85° (opt.), and 6.8% for 45°. For the reaction: $NiCl_2 + 6NH_4OH = [Ni(NH_3)_6]Cl_2 + 6H_2O$, K decreases with increasing NH_3 and with decreasing Ni concn. (No figures given). The expts. show that Beer's law does not hold true for these reactions. In order to become applicable it would have to be changed to $(c_1/c_2)^x = d_1/d_2$, where x would vary with the reaction. Colorimetry could in such cases be replaced advantageously by spectrophotometry. MARY JACOBSEN

Diphenylamine as indicator in the titration of iron with dichromate. F. J. WATSON. *Chem. Eng. Mining Review* **22**, 355–7(1928).—Because of the fact that the results obtained with students using diphenylamine as indicator were not thoroughly satisfactory, the titration was studied with diphenylamine and potentiometrically. With a sulfate soln. in which the electrometric end point occurred when 19.92 cc. of $K_2Cr_2O_7$ were added, the first change in color from the clear green of Cr^{+++} began at about 18.6 cc. and as each drop of dichromate was added the green became duller and was a very cold, gray green at about 1 drop before the electrometric end point. A purple color became distinct at the electrometric end point. In HCl solns. the color at the end point was bluer but, in the latter case, the presence of $HgCl_2$ caused tardiness in the development of the purple color and with 10 cc. of satd. $HgCl_2$ soln. 2 cc. of excess dichromate were required. Knop's arbitrary deductions of 0.05 cc. from the total dichromate used does not seem to be the correct procedure as the purple color appears at the true end point

normally When the first change in color is noticed the dichromate should be added dropwise, waiting a definite time after each addn. The indicator change is reversible; hence an over-shot end point can be back titrated but the final end point should always be the development of color with dichromate. When reducing Fe^{+++} with $SnCl_2$, add the reagent dropwise to the boiling soln. and do not add more than 2 drops in excess. Cool and add only a few drops of $HgCl_2$ soln Standardize the soln. against Mohr's salt with diphenylamine as indicator. W. T. H.

A specific reagent for silver and a new, sensitive test for silver. F. FEIGL. Univ. Wien. *Z. anal. Chem.* **74**, 380-6(1928). -Rhodanine, $C_3H_3NOS_2$, gives an insol. ppt. with Ag^+ and with Hg^{++} ions and this characteristic is retained by many rhodanine derivs., among which *p*-dimethylaminobenzylidenerhodanine is especially suitable as a sp. reagent for Ag To prep. this deriv, dissolve equimol. quantities of rhodanine and *p*-dimethylaminobenzaldehyde in glacial AcOH and heat 1 hr. under a reflux condenser. The red crystals begin to sinter at 200° and m. 246°. Dissolve 0.03 g. of the crystals in 100 cc. of acetone. Add a little of this reagent to the acid soln. to be tested and a reddish violet ppt will form if 0.001 mg. is present. The reaction is so sensitive that it is useful for a micro test. Thus, to detect Ag in a coin, rub the metal against a streak stone so that a light line is obtained. Add a drop of HNO_3 and evap. with a flame Then moisten the streak with the reagent and add a few drops of 6 *N* HNO_3. W. T. H.

Application of rapid electroanalysis by graded potentials to commercial alloys. ARNOLD LASSIEUR. *Chimie et industrie* Special No., 129-30(April, 1928); cf. *C. A* **21**, 1071.—The Lassieur method enables Sb, Cu, Bi, Pb, Sn, Cd, Zn and Ni to be sepd and detd electrolytically in the same soln., so that bronzes, brasses, solders, plating metals, bearing alloys, type metals, German silver, Al alloys, and commercial Cu, Sb, Pb and Zn can be analyzed without having to carry out any evapns., filtrations and pptns. The latter operations are required only for the detn of impurities which are present in small quantities in commercial metals. The method is in daily use in the Paris municipal labs, where it is giving satisfactory results. A. P.-C.

Quantitative spectral analysis of metallic alloys. TR. NEGRESCO. *J. chim. phys.* **25**, 343-62(1928); cf. *C. A.* **21**, 3848.—Though the intensity of spectral lines diminishes with the decreased amt of the element in the source, no law can be given for the variation To analyze an alloy by the spectral method it is first necessary to obtain the spectra of known standards of all possible compns. of the alloy and then, having obtained the spectra of the alloy in question, compare the intensities of given lines with the standards. All phys. conditions must be kept the same. Comparative tables are given for alloys of Sn-Bi, Pb-Bi, Cu-Si, Fe-Si, Cu-Co and Zn-Cd E. G. VANDENBOSCHE

Quantitative separations and determination by volatilization with hydrogen chloride. VI. Determination of oxide in aluminum alloys. G. JANDER AND W. BRÖSSE. *Z. angew Chem.* **41**, 702-4(1928). The method recently described (*C. A.* **21**, 2239) for the sepn. of Al, Si and Mg, etc., in Al alloys can be used for the accurate detn. of the Al_2O_3 present in such alloys, if not less than 0.02% is present. Under the prescribed conditions of drying, moisture is sufficiently eliminated from the gaseous HCl, and further drying by cooling to −78° to −80° with ether and solid CO_2 is unnecessary. An internal reaction temp. of about 275° is used instead of 200-220° as originally recommended. B. C. A.

Potentiometric analysis of the hardening elements in special steels. II. Determination of chromium and vanadium in iron alloys and in alloy steels. E. ZINTL AND P. ZAIMIS. *Z. angew Chem* **41**, 543-6(1928); cf. *C. A.* **22**, 556.—In the detn. of Cr and V by the author's potentiometric method, the presence of Fe is not essential. Small quantities of Mn must however, be present. W interferes with the detn. of V, but not in the presence of H_3PO_4. The sample taken for analysis (0.5-5 g., depending on the Cr and V content) is fused with 6-10 times its own weight of Na_2O_2 and, after cooling, extd. with 2 *N* NaOH. A few cc. of H_2O_2 are added to decompose manganate and ferrate, and the whole is boiled. After filtration, the filtrate, which contains the whole of the Cr, V, Mo and W as chromate, vanadate, molybdate and tungstate, resp., is diluted to an appropriate vol. A suitable aliquot is acidified with 100 cc. of 1:1 (vol.) H_2SO_4, 2-3 cc. of a dil. $MnSO_4$ soln. (120 mg. of crystals per l.) are added, and after diln. to 200 cc. the titration is effected as described. If W is present, the aliquot is treated with 30 cc. of H_3PO_4 (d 1.74) before the addn. of the H_2SO_4. The catalytic effect of the small quantity of Mn is discussed. B. C. A.

Rapid analysis of brass and bronze. M. RUDOLPH. *Chem.-Ztg.* **52**, 652(1928); K. MASL AND CH. OS. STEYRER. *Ibid.* SEUFERT. *Ibid.* Kollrepp (*C. A.* **22**, 1744)

published a method depending upon dissolving the alloy in HNO_3, removing SnO_2, pptg. Pb as $PbSO_4$, Cu as CuS, Ni as glyoxime deriv. and Zn as ZnS. The fact that the procedure of K. is unnecessarily long and troublesome and that better procedures are well known is pointed out independently in 3 letters to the editor. W. T. H.

The detection of magnesium in minerals by means of the diphenylcarbazide test. F. Feigl. Univ. Wien. *Z. anal. Chem.* **74,** 398–9(1928); cf. *C. A.* **22,** 41.—F. pointed out some time ago that the diphenylcarbazide test can be obtained with magnesite but not with dolomite. Recent x-ray studies by Halla (to be published elsewhere) show that F.'s idea that dolomite is $Ca[Mg(CO_3)_2]$ is possibly true. Similarly aragonite is very likely $CaCO_3$ and calcite is $Ca[Ca(CO_3)_2]$. W. T. H.

Notes on the determination of molybdenum. H. A. Doerner. Bur. Mines, *Information Circular* No. 6079, 2 pp.(1928).—The method, which is dissussed in U. S Bur Mines, *Bull.* **212,** depends upon dissolving the sample in aqua regia, evapg. with H_2SO_4, removing $PbSO_4$ and adding NH_4OH and 3 g. of Na_2CO_3 to the filtrate therefrom. This serves to ppt. Ca and other interfering ions. After thorough digestion the ppt. of carbonates and hydroxides is removed, tartaric acid and H_2S are added and any ppt. that forms is removed. The alk. sulfide soln. is then made acid and MoS_3 filtered off. The MoS_3 is dissolved in aqua regia and a $PbMoO_4$ ppt. is formed in a properly buffered soln. and weighed. W. T. H.

Investigations into the analytical chemistry of tantalum, columbium and their mineral associates. XII. Observations on the pyrosulfate-hydrolysis method. W. R. Schoeller and E. F. Waterhouse. Sir John Case Tech. Inst. *Analyst* **53,** 467–75(1928).—Expts. show that it is practically impossible to accomplish a satisfactory sepn. of the earth-acids from zirconia by any of the hydrolysis methods upon which so much emphasis has been placed in the past. ZrO_2 is likely to ppt. with Ta_2O_5 or Nb_2O_5 and if the acid concn. is made high enough to prevent pptn. of ZrO_2 then some of the earth-acid will remain in soln. Similarly with TiO_2 and the further complication arises that Zr tends to prevent the complete pptn. of TiO_2 by hydrolysis and of the earth-acids when Ti is present. The sepn. of the earth-acids from $Fe_2(SO_4)_3$ by hydrolytic pptn is also not feasible; the sepn. from $FeSO_4$ is better but by no means ideal. As the knowledge of the earth-acids becomes more complete, the idea of pptg. them by hydrolysis falls into disuse. W. T. H.

New precipitation method for the determination of vanadium and its application to steel analysis. B. S. Evans and S. G. Clarke. *Analyst* **53,** 475–86(1928).—In alk. citrate soln. of tervalent Fe salt, a reducing agent, such as $Na_2S_2O_4$, together with KCN converts Fe^{+++} completely into ferrocyanide from which the usual reactions of Fe cations cannot be obtained. If V is present at the same time, vanadyl ferrocyanide, a pale yellow gelatinous ppt. of somewhat uncertain compn., is formed on making the soln acid. This ppt. is remarkably insol. in mineral acid solns. of fairly high concn. Thus a few mg. of V can be completely pptd. by $K_4Fe(CN)_6$. *To det. V in steel,* treat 5 g. of sample in a 750-cc. Erlenmeyer flask with 80 cc. of 4.5 *N* H_2SO_4, eventually adding about 5 cc. of concd. HNO_3 to clear up the carbonaceous residue and digesting long enough to produce pure yellow WO_3 if W is present. Add 70 cc. of 50% citric acid soln and enough of hot concd. Na_2CO_3 soln. to make the soln. *faintly* alk. to litmus paper but avoiding an excess. If Ni is present it must be removed. For this purpose, add 100 cc. of a 1% soln. of dimethylglyoxime in hot alc. and filter off the Ni ppt. after it has been allowed to form during 15 min. in a warm place. (If more than 4–5% of Ni is present, more glyoxime must be used.) If the Ni is not removed, an unfiltrable ppt. of Ni ferrocyanide will be obtained subsequently. After removing the Ni glyoxime, cool the soln. somewhat, add 25 g. of $Na_2S_2O_4$ and 40–45 g. of KCN dissolved in 100 cc. of water. Dissolve the KCN in the water by gently heating, but not boiling, and allow the soln. to cool somewhat before adding it to the main soln. to which the sulfite has just been added. Shake the contents of the flask after adding the cyanide until the sulfite has all dissolved. A rise of temp. will take place in the soln. and the color will begin to fade. (The presence of Ni causes the red color to persist and when Cr is present, the pure ferrocyanide color is never obtained.) Heat the soln. for about 10 min. just below the b. p. To make sure that all of the Fe has been converted into ferrocyanide, take a few cc. of soln. in a small beaker and make it acid with H_2SO_4; if a Prussian blue color is obtained the conversion is incomplete and the soln. must be heated longer, adding more KCN if necessary. Usually a light brown ppt. of Mn ferrocyanide forms during the conversion of the Fe to ferrocyanide; this ppt. should not be removed because it will contain V. Allow the soln. to cool to about 30°, make neutral to litmus with 9 *N* H_2SO_4 and add 70 cc. of the acid in excess Allow to stand at least 2 hrs., add filter paper pulp and filter. Wash the ppt. with 2% NH_4NO_3 soln., disturbing

the ppt. as little as possible. Ignite the ppt in a Pt dish and fuse with Na_3PO_4 and 5 times as much $KNaCO_3$. Extract the melt with hot water, filter, wash with dil. Na_3PO_4 soln. and acidify the filtrate with 9 *N* H_2SO_4, adding about 5% in excess. Add a few pieces of unglazed porcelain, sat. with SO_2, boil off the excess and titrate the hot reduced soln. with $KMnO_4$. For the detn. of very small quantities of V in steel, proceed as outlined above, but filter off WO_3 if present. Then, after the conversion to ferrocyanide, add 150–200 cc. of H_2SO_4 in excess instead of 70 cc. After the fusion, conc. the extract to about 60 cc., cool, add 20 cc. of concd. H_2SO_4 and a few drops of dil. $KMnO_4$ to make sure that the V is all in the quinquevalent condition. Transfer to a Nessler tube and det. the V colorimetrically by the H_2O_2 reaction. If Mo is present, add 10 g. of NaF before pptg. the V ferrocyanide and finally remove Mo in the usual way with H_2S before detg. V. colorimetrically. W. T. H.

Determination of minute amounts of mercury. A. STOCK AND W. ZIMMERMANN. *Z. angew. Chem.* **41**, 546–8(1928).—A method for the detn. of quantities of Hg of the order $10^{-3} - 5 \times 10^{-5}$ mg. and for the detection of amts. of the order 7×10^{-6} mg. is described. The initial stages are similar to those already described (*C. A.* **20**, 2297, 3144), save that deposition on a Cu wire is effected in evacuated app. and at 50–60°. The sublimate obtained on distn. is dissolved in 0.25 cc. of chlorine water and excess of Cl expelled by air. The soln. is treated with a drop of a cold, satd. soln. of carbamide and diluted to 0.5 cc. in the cell of a microcolorimeter. The blue color produced on addn. of a drop of a satd., alc. soln. of diphenylcarbazone is observed in a darkened room by yellow light. Comparative tests are made with solns. of pure $HgCl_2$ under identical conditions. B. C. A.

Determination of ammonia. K. TÄUFEL AND C. WAGNER. *Z. angew. Chem.* **41**, 285–7(1928).—The details of manipulation and of the precautions to be taken in the detn. of small quantities of NH_3, in presence of nitrogenous materials readily decompd. with formation of NH_3, are discussed for the methods of blowing through large quantities of air and of distg. with excess of MgO. In the latter method low results are obtained if the soln. to be distd. contains considerable Mg salt. B. C. A.

A simplified method for the determination of carbon dioxide, ammonia and hydrogen sulfide in the air of dwelling rooms. K. SÜPFLE, P. HOFMANN AND L. WALZ. *Arch. Hyg.* **98**, 147–57(1927).—Concordant results were obtained when the air was passed through 25 cc. 0.1 *N* H_2SO_4 in a round-bottom flask, then through a $CaCl_2$ tube, next over bits of pumice (previously soaked in hot concd $CuSO_4$ and dried at 150–160°) and finally through a KOH bulb The gain in wt. of the H_2SO_4 showed the NH_3 content, of the pumice-$AuSO_4$ tube the H_2S, and of the KOH bulb the CO_2. P. Y. J.

Titrimetric determination of germanic acid. Studies on some hydrates formed of this acid and of its salts. ARAKEL TCHAKIRIAN. *Compt. rend.* **187**, 229–31(1928).—Ten g. of GeO_2 will dissolve in 1 l. of water contg. 20 g. of mannitol. In the presence of the mannitol, the soln can be titrated with NaOH toward which it reacts as a monobasic acid with phenolphthalein as indicator. If 20 g. of $CaCl_2$ or $SrCl_2$ is added to 10 cc. of the GeO_2 soln., it then reacts as a dibasic acid. Ge can also be titrated iodometrically. If the aq. soln. is allowed to act upon a mixt. of KI and KIO_3, at the end of 3 hrs 1 atom of I will be formed from each atom of Ge. In the presence of strong electrolytes, and at the end of 12 hrs., one mol. of I_2 is liberated. This permits the titration of Ge in the presence of strong acids. First, the strong acid is eliminated by treatment with KI and KIO_3 and the soln. is carefully decolorized with $Na_2S_2O_3$. Then after adding mannitol and allowing the soln. to stand 3 hrs. the Ge is titrated indirectly with thiosulfate. When GeO_2 is dissolved in water, the satd. soln. contains 0.8% of Ge probably present as H_2GeO_3. After mannitol has been added, an acid $H_2Ge_2M_nO_5$, is probably formed in which *M* represents a mol. of mannitol and the subscript *n* is 8 or more. In the presence of a strong electrolyte, the formation of $H_2CaGeCl_2O_3$ is postulated. W. T. H.

Notes on the detection of phosphate and molybdate. F. FEIGL. Univ. Vienna. *Z. anal. Chem.* **74**, 386–92(1928).—Yellow $(NH_4)_3PO_4.12MoO_3$ moistened with benzidine acetate soln. and brought in contact with NH_3 gives a deep blue coloration. The test is so sensitive that it responds to filter paper through which a molybdate soln. contg. so little PO_4^{---} has been passed, that there is no visible sign of a yellow ppt. Moreover, the corresponding AsO_4^{---} compd. reacts so slowly with benzidine that traces of PO_4^{---} can be detected in the presence of considerable AsO_4^{---}. The test can be used as a spot test or 2 cc. of the soln. can be treated with 3 drops of acid molybdate soln. and some satd. benzidine acetate soln. and 1% NH_3 added until a permanent turbidity is formed; a blue coloration will be obtained if 0.00066 mg. of P_2O_5 is present. There seems to be no indication in the literature that when $C_2O_4^{--}$ is present it requires

more MoO_4^{--} to give the characteristic test for PO_4^{---} than is normally necessary. It is also true that the presence of MoO_4^{--} tends to make the usual tests for $C_2O_4^{--}$ less sensitive. This indicates the formation of a complex oxalate-molybdate ion.

W. T. H.

A new and sensitive method for the detection of sulfides and thiosulfates. F. Feigl. Univ. Wien. *Z. anal. Chem.* **74**, 369–76(1928).—Raschig, in 1915, pointed out that solns. of NaN_3 and I_2 do not react together by themselves but evolve N_2 when a little $Na_2S_2O_3$ or Na_2S is added. The reaction is so sensitive that it responds to as little as 0.002 mg. of H_2S and can be obtained with insol. sulfides. Solid CuS reacts more slowly than HgS. To carry out the test, treat about 0.05 g. of the powd. substance with 5 cc. of a mixt. of equal parts 0.1 *N* NaN_3 and 0.1 *N* I_2 soln. The reaction is not obtained with free S, sulfates, selenides, tellurides, arsenides or antimonides and, in the absence of thiosulfate or thiocyanate (the last may be regarded as a sulfide), appears to be one of the most sensitive as well as most characteristic tests ever suggested for the sulfide ion.

W. T. H.

Iodometric determination of persulfates. Alfred Schwicker. Chem. Lande-inst. Budapest. *Z. anal. Chem.* **74**, 433–41(1928).—Mondolfo (*Chem.-Ztg.* **23**, 699) heated $K_2S_2O_8$ 5–10 min. with KI soln. and titrated the liberated I_2 with $Na_2S_2O_3$. If the amt. of KI is increased to 4 g. for 0.2 g. $K_2S_2O_8$ in 10 cc. of water, the reaction requires only 10 min. at room temp. The most convenient way to prepare 100 cc. of 0.1 *N* I_2 soln. is to dissolve 1.352 g. of $K_2S_2O_8$ in 25 cc. of water, add 4–5 g. of KI and dil. to 100 cc. after the reaction has been allowed not more than 1 hr. to become complete. Müller and Ferber (*Ber.* **38**, 3965) used $FeSO_4$ to accelerate the reaction between persulfate and iodide in neutral soln. The reaction will take place promptly if 4 g. KI is used without the $FeSO_4$ or 3 g. of NH_4Cl with 1 g. of KI. Müller (*C. A.* **7**, 2173) also published a method for converting iodide to iodate by the action of persulfate in alk. soln.; then the IO_3^- is measured by treating with acid and titrating the evolved I_2. This method does not apply to $(NH_4)_2S_2O_8$ because some nitrite is formed. M. noted that the presence of H_2O_2 caused difficulty but this can be overcome by first adding enough $KMnO_4$ to the acid soln. after detg. how much permanganate is needed by a special expt. Kolthoff (*Z. anal. Chem.* **60**, 455) has made use of the fact that ferricyanide is formed from ferrocyanide by treatment with persulfate in neutral soln. Then on adding KI and acid, I_2 is liberated and can be titrated with thiosulfate. This method was tested and found to be excellent. Müller and Dieferthäler (*C. A.* **4**, 2783) started with the same original reaction but detd. the excess ferrocyanide by titration with $KMnO_4$. This method also is shown to be good. Finally, it is possible to analyze a persulfate by causing it to react with an excess of $SnCl_2$ and titrating the excess iodometrically. This method also gives good results.

W. T. H.

Volumetric method for determination of sulfate ion. Frederick G. Germuth. *J. Am. Water Works Assocn.* **19**, 607–9(1928).—The method described advocates the employment of 0.02 *N* $BaCl_2$ as precipitant, and subsequently back titration with 0.02 *N* K_2CrO_4, the end point being det. by the utilization of $Pb(NO_3)_2$ as outside indicator. Greater accuracy is claimed for this method as compared to that of Wildenstein, from which it differs both in concn. of solns. used as well as choice of outside indicator.

F. G. Germuth

Determination of hydrocarbon vapors in air by means of active charcoal. E. Posner. Forschungs lab. des Volkskommisariats für Arbeit des A. S. S. R., Baku. *Z. anorg. allgem. Chem.* **174**, 290–4(1928).—"Zelinsky" and "Bayer A. K. H." charcoals were used for the quant. adsorption of hydrocarbon vapors from a measured current of dry, CO_2-free air (about 60 l./hr.). The gain in wt. of the charcoal tube was detd. Various vapors, such as hexane, benzene, kerosene, gasolene, were detd. in control expts. involving known amts. between 0.79 and 5.5 mg./l. The known air-vapor mixts. were made by humidification of the air stream at proper temps. The observed results check those calcd. from the vapor pressures within ± 0.05 mg./l.

R. L. Dodge

The analytical utilization of a catalysis produced by carbon bisulfide for the iodometric determination of azides and for the detection of carbon disulfide. F. Feigl and E. Chargav. Univ. Wien. *Z. anal. Chem.* **74**, 376–80(1928).—The reaction $2\ NaN_3 + I_2 = 2\ NaI + 3\ N_2$ takes place if a little CS_2 is present and can be used for the detection of very small quantities of CS_2 and for the detn. of azides. The reaction takes place in 2 stages. The Na salt of azidodithiocarbonic acid is first formed by the reaction of CS_2 with NaN_3 and is at once oxidized by the I_2 present, giving back the original CS_2. To 5 cc. of an aq. soln. of CS_2 add 1–2 cc. of a soln. which is 0.5 *N* in NaN_3 and 0.1 *N* in I_2. If 0.02 mg. of CS_2 is present there will be an immediate evolution of N_2. If H_2S is present, first oxidize it with I_2 before applying the test. For the evalua-

tion of NaN_3, place 0.5 cc. of CS_2 and 6–8 cc. of pure acetone in a 500-cc. flask, add a moderate excess of 0.1 *N* I_2 soln. and a definite vol. of the azide soln. Shake and after 5–10 min. titrate the excess I_2 with arsenite soln. W. T. H.

The determination of reducing sugar. N. SEMIGANOVSKII. Chem. Pharm. Inst. of Moscow. *Z. anal. Chem.* **74,** 400–2(1928); *Trans. Sci. Chem.-Pharm. Inst.* (Moscow) **1926,** 33–5.—An interesting method of analyzing the Cu_2O ppt. produced by the action of a reducing sugar on Fehling's soln. consists in treating the well-washed ppt. with a soln. contg. 15% NaCl, 1% HCl and 0.5% $MnSO_4$ Then by adding 0 2% $KMnO_4$, the $Cu_2Cl_4^{--}$ soln. is converted into Cu^{++} which can be titrated by the iodide method (adding an excess of KI and titrating the liberated I_2 with $Na_2S_2O_3$). W. T. H.

Analysis of Se (KRAK) **18.** Se cells as colorimeters (MICKWITZ) **2.**

CORNOG, JACOB, AND VOSBURGH, WARREN C.: **Introductory Qualitative Analysis.** New York: The Macmillan Co. 155 pp. $1.60.

GOOCH, FRANK AUSTIN AND BROWNING, PHILIP EMBURY: **Outlines of Qualitative Chemical Analysis.** 6th ed. revised. New York: J. Wiley & Sons, Inc.; London: Chapman & Hall, Ltd. 206 pp. $1.75.

8—MINERALOGICAL AND GEOLOGICAL CHEMISTRY

EDGAR T. WHERRY AND J. F. SCHAIRER

Methods for the microscopic examination of metallic minerals. J. ORCEL. *Bull. soc. encour. ind. natl.* **1928,** No. 6, 503–27; cf. *C. A.* **22,** 2529.—The use of the microscope in the study of minerals in America and Germany is reviewed. Modern methods and app. are described and results are recorded of the microexamn. of thin sections or of polished surfaces of niccolite, covellite, famatinite, bournonite, chloanthite, gersdorffite, bismuthinite, sphalerite, galena, pyrite and arsenopyrite. L. W. RIGGS

Magnetic, electrochemical and photochemical tests in the identification of opaque minerals. H. E. MCKINSTRY. Harvard Univ. *Econ. Geol.* **22,** 669–77(1927).—Pt electrodes sealed in a glass tube and connected to 2 dry batteries are used in drops on the surface of polished sections to facilitate etching, to help bring a mineral into soln. for microchem. tests, and to obtain a qual. test for Cu on a no. of minerals Certain Ag minerals, as cerargyrite, sulfides, sulfarsenides and sulfantimonides, develop tiny, shining yellowish globules or blebs on a strongly illuminated surface which may be conveniently observed under the oil immersion objective on a reflecting microscope. ELLIOTT J. ROBERTS

The equilibrium diagram of pyrrhotite and pentlandite and their relations in natural occurrences. W. H. NEWHOUSE. *Econ. Geol.* **22,** 288–99(1927).—Cooling curve data are given for mixts. of FeS and NiS + S contg. up to 50% NiS. With rapid cooling, pyrrhotite may be secured contg. up to 13% Ni in solid soln. ELLIOTT J. ROBERTS

Crystallographic investigations of the pyrite of Komitates Krassó-Szörény. KAROLY ZIMÁNYI. *Matematik. Természettudományi Értesitö* **41,** 152–7(Hung.), 158(Ger.). (1925); cf. *C. A.* **18,** 647.—Pyrite occurs at least as an accessory mineral in all the mines of the region. Crystallographic data are given for a large no. of different types of crystals. J. S. REICHERT

Occurrence of tridymite and cristobalite in a granitic xenolith. A. ALLEN WEYMOUTH. *Am. J. Sci.* **16,** 237–8(1928).—The xenolith that furnished the material for this study was found in a road cut 10 miles north of New Meadows, Idaho. It contained quartz, orthoclase, oligoclase, muscovite, biotite, chlorite, garnet, Fe oxide, zircon, tridymite and cristobalite. The tridymite, forming nearly 1% of the rock, occurred in apparently isotropic flakes, with mean n = 1.475. The cristobalite, which was present in a much smaller proportion than 1%, had the same optical properties as tridymite except that n = 1.485. A silica brick, which had been heat treated at 1400°, contained 70–75% of cristobalite identical with that found in the xenolith except for its lack of inclusions. L. W. RIGGS

Two kinds of magnetite. W. H. NEWHOUSE AND W. H. CALLAHAN. Mass. Inst. Technology. *Econ. Geol.* **22,** 629–32(1927).—N. and C. suggest that the brown magnetite found in various localities is "oxidized magnetite" similar to that described by Sosman and Posnjak (*C. A.* **19,** 3077). ELLIOTT J. ROBERTS

Dehydrated gibbsite. JACQUES DELAPPARENT AND ERNEST STEMPFEL. *Compt.*

rend. **187,** 305–6(1928).—Gibbsite, prepd. by the method of Bayer, forms hexagonal prisms. On heating by stages the hexagonal crystals undergo various changes at different temps. and at 600° become orthorhombic. L. W. RIGGS

Crystallographic examination of Hungarian calcites. MÁRIÁ VENDL. *Matematik. Természettudományi Ertesitö* **43,** 255–63(Hung.), 264–5(Ger.), (1926); cf. *C. A.* **21,** 1610.—A description of 42 forms of crystals of calcite from various localities. J. S. REICHERT

Analysis of Hungarian dolomite crystals. ILONA STROBENTZ. *Földtani Közlöny* **55,** 49–57 (Hung.), 275 (Ger.) (1925) (published 1926); *Mineralog. Abstracts* **3,** 301 (1927).—The following 15 analyses were made on carefully selected crystd. material from 11 Hungarian localities.

	CaO	MgO	FeO	Fe_2O_3	Al_2O_3	CO_2	Insol.	Total
(1) Normal dolomite without FeO; $CaMg(CO_3)_2$								
Selmeczbánya	31.22	21.36	—	0.14		47.22	0.37	100.31
Selmeczbánya	32.76	19.97	—	0.31		47.31	0.22	100.5[illegible]
Kapnikbánya	31.04	21.02	—	0.68	0.58	46.90	0.14	100.36
Nagybánya	29.60	21.60	—	0.35	0.23	46.50	1.49	99.77
(2) Dolomite without FeO; $Ca_3Mg(CO_3)_4$								
Selmeczbánya	43.71	9.81	—	0.22	0.14	44.23	1.83	99.94
(3) Dolomite with small quantities of FeO; $Ca(Mg,Fe)(CO_3)_2$								
Úrvölgy	30.84	19.63	1.67	—	0.51	46.67	0.07	99.39
Óradna	31.15	19.61	1.33		1.89	46.94		100.92
(4) Dolomite with more than 5% FeO (ankerite); $Ca(Mg,Fe)(CO_3)_2$								
Boicza	33.23	7.78	12.81	2.57		42.31		98.70
Vaskö	30.69	15.16	6.74	1.27	2.18	44.65	0.22	100.91
Vaskö	28.93	17.23	5.66	—	2.26	44.87	1.58	100.53

Ötösbánya	27.55	11.22	17.10	—	1.58	42.74	0.74	100.93
(5) Ankerite in which FeO replaces CaO; $(Ca, Fe)(Mg,Fe)(CO_3)_2$								
Felsöbánya	13.68	14.47	26.00	—	0.31	42.32	3.53	100.31
(6) Dolomite with MnO; $Ca(Mg,Mn,Fe)(CO_3)_2$								
Hodrusbánya	33.84	14.27	1.68	3.97	—	44.21	—	99.84*
Vaskö	27.13	14.31	1.28	—	2.32	47.26	0.39	99.08†

*Also MnO 1.87 †Also MnO 6.39

The ankerite from Felsöbánya occurs as lenticular rhombohedra on quartz with wolframite. The sp. grs. of the materials analyzed were not detd. H. G.

Crystallographic monograph on Hungarian cerussite. LÁSZLÓ TOKODY. *Matematik. Természettudományi Ertesitö* **43,** 382–94(Hung.), 395–6(Ger.), (1926).—Crystallographic data on 49 forms are given. J. S. REICHERT

The riebeckite of Alter Pedroso. ALADÁR VENDL. *Matematik. Természettudományi Ertesitö* **41,** 206–13(Hung.), 214(Ger.) (1925).—The pegmatitic veins of alkali syenite of Alter Pedroso carry an amphibole in large individuals. This amphibole, previously identified as riebeckite, is shown to belong to the osannite series. The optic axial plane is ⊥ the symmetry plane. βx_a:C = $1^1/_4$°, for red = 0°, and for blue = 3–5° in the angle β; index β = 1.6934; sp. gr. = 3.371. From the analysis: SiO_2 49.92, TiO_2 0.65, Al_2O_3 1.99, Fe_2O_3 13.35, FeO 18.46, MnO 2.24, MgO 2.07, CaO 1.25, Na_2O 6.55, K_2O 0.95, H_2O^- 0.24, H_2O^+ 2.03 and F 0.45, the following components were calcd.: riebeckite 39.98, glaucophane 9.28, arfvedsonite 29.79, and actinolite 20.95%. J. S. REICHERT

Study of the chlorites by means of x-rays. CH. MAUGUIN. *Compt. rend.* **186,** 1852–5(1928).—Three chlorites, penninnite, leuchtenbergite, and grochauite, though differing widely in chem. compn., show similar crystal structures and unit cells of the same size. In each the unit appears to contain 18 O atoms and 18 electro-positive atoms (Si, Mg, Fe^{++}, Fe^{+++} and Al). Substitution among the electropositive atoms which preserves the proper valence relations appears possible without disturbing the crystal structure. In this behavior the chlorites are analogous to the micas. The rotating crystal method was used. R. L. HERSHEY

Whewellite crystals from Kapnikbánya. SÁNDOR KOCH. *Matematik. Természettudományi Ertesitö* **42,** 151–6(Hung.), 157(Ger.), (1926).—Data on the structure of a water-white crystal 67 × 45.5 × 40 mm. in size are given. J. S. REICHERT

Ajkaite, a fossil resin from Hungary. LÁSZLÓ ZECHMEISTER. *Matematik. Természettudományi Ertesitö* **43,** 332–40(Hung.), 341(Ger.), (1926).—In the lignite deposits at Ajka, nut-size resinous inclusions are present. The hardness $2^1/_2$, sp. gr. =

1.05–6, n_D^{18} = 1.5412, color yellow to dark brown, m. p. indefinite; it is slightly sol. in alc. and ether, 4% sol. in $CHCl_3$, and contains no ash, N_2, or halogen. A light yellow sample contains C 80.38, H 11.00, O 7.20, S 1.42%, a dark one C 79.01, H 9.89, O 9.61, S 1.49%. Acid value 0, saponification no. about 160. Upon heating H_2S escapes first, then an oil (82% of the wt. of the resin) which contains O and but little S. No succinic acid is obtained by heating or by a treatment with alkali. When boiled with HNO_3 (1:2) it takes up 6.5% N. J. S. Reichert

Intimate intergrowths and mutual boundaries as proof of contemporaneous deposition. W. H. Newhouse. *Econ. Geol.* **22**, 403–7(1927).—Hematite was artificially replaced by magnetite by application of a reducing flame. Bornite and chalcopyrite were partially replaced by chalcocite by immersing polished specimens in a strong $CuSO_4$ soln. for several days at about 70°. Elliott J. Roberts

Classification of magmatic ore deposits. A. N. Zavaritskii. Mining Inst., Leningrad, Russia. *Econ. Geol.* **22**, 678–86(1927).—Z. presents a physico-chem. scheme of classification for magmatic ore deposits: (*A*) Deposits formed by crystn. differentiation. (1) Accumulative deposits, (2) "Fusive" deposits. (*B*) Liquation deposits. (1) Straight liquation deposits, (2) Syntectic liquation deposits. Examples are given. Elliott J. Roberts

Recent evidence confirming the zonal arrangement of minerals in the Cornish lodes. E. H. Davison. *Econ. Geol.* **22**, 475–9(1927).—Observations on 3 new shafts and a tunnel near Camborne, Cornwall, Eng., confirm D.'s previous conclusions with regard to the zonal arrangement of the minerals in this district (Handbook of Cornish Geology, 1926). E. J. Roberts

Mineral deposits of the Hyder district, southeastern Alaska. W. B. Jewell. Vanderbilt Univ. *Econ. Geol.* **22**, 494–517(1927).—A peculiar zoning is present in which pyrite, galena, chalcopyrite, tetrahedrite-freibergite, quartz and barite show a tendency to occur in the genetically associated intrusive, and pyrrhotite, arsenopyrite, sphalerite and calcite in the roof rocks. The parent magma was probably relatively dry. Five minerals are described, associated with galena and tetrahedrite in the polished sections, which could not be identified. Elliott J. Roberts

Oxidation products derived from sphalerite and galena. P. F. Boswell and Roland Blanchard. *Econ. Geol.* **22**, 419–53(1927).—Sphalerite and galena may dissolve without generation of, or attack by, Fe-bearing solns., thus leaving no limonite. Neither primary nor secondary Zn minerals are as likely to remain in a leached cropping as are primary and secondary Pb minerals, once oxidation is well advanced. Elliott J. Roberts

Ore deposits of the Rio Tinto (Huelva) district, Spain. Alan M. Bateman. Yale Univ. *Econ. Geol.* **22**, 569–614(1927).—The following minerals, previously unreported from this district, were identified in polished sections: luzonite, famatinite, chalcostibite, whitneyite, umangite, hauchecornite, ullmanite, berthierite and three undetd. These minerals account for the presence of small amts. of Ag, Bi, Ni, Co, Sb and Se found in the ore. The ore bodies, consisting chiefly of pyrite, are normal hydrothermal replacement deposits, having been formed by aqueous solns. replacing the adjacent porphyry and slate with sulfides. Elliott J. Roberts

Tourmaline-bearing cinnabar veins of the Mazatzal mountains, Arizona. K. Hummel. *Econ. Geol.* **22**, 407–8(1927).—This deposit possibly formed by secondary enrichment of a high temp. Cu tourmaline deposit exceptionally rich in mercurial tetrahedrite. Elliott J. Roberts

Geology of the platinum metals. J. H. L. Vogt. *Econ. Geol.* **22**, 321–55(1927).—A review of the genesis of Pt-bearing deposits in general, including a summary of old analyses of Pt and the associated rocks, and a summary of the world's production from 1860 to 1922. The deposits fall into 2 main types (1) occurring in dunites (and pyroxenites); and (2) occurring in nickeliferous pyrrhotite in norite; both are due to magmatic differentiation. Elliott J. Roberts

Origin of the Gunflint iron-bearing formation. J. E. Gill. Univ. of Rochester, N. Y. *Econ. Geol.* **22**, 687–728(1927).—SiO_2 and Fe in colloidal soln. were pptd. slowly at some distance from the river mouths. The pptn. is believed to have been entirely independent of organisms. Elliott J. Roberts

Geological relations of the North African iron ores. Per Geijer. Geol. Survey, Stockholm, Sweden. *Econ. Geol.* **22**, 537–64(1927).—A survey, based on the literature and a personal visit. Total ore reserves are estd. to be > 100 million tons. Low P, S, and SiO_2 characterize the greater part of the ore. Fe runs 55–60%. Part of the ores are of the Bilbao type being originally siderite, now extensively replaced by hema-

tite. The other type was originally magnetite, now partially oxidized to hematite. These latter ores are low in Mn, while the former run from 1 to 2%. E. J. R.

The natural resources of Wales. F. J. North. *Brit. Clayworker* 37, 190–1 (1928).—A non-technical description of how clay is formed. Different types of clays in Wales, their possible origin, and various products manufactured from them, are discussed. R. A. Heindl

Solikamsk carnallite and sylvite. D. Shtern and P. Levin. *J. Chem. Ind. (Moscow)* 5, 382–5(1928); cf. Volf and Yatlov, *C. A.* 22, 3495; Efremov and Veselovskii, *C. A.* 22, 3495.—The compn. of Solikamsk K salts compared with those of Stassfurt and the Dead Sea is as follows:

	% KCl	% $MgCl_2$	% NaCl	% anhydrite	% $CaCl_2$
Solikamsk carnallite	23.5	26	20.5	1/2	–
Stassfurt carnallite	16–20	20–25	24	0.5–2	–
Solikamsk sylvite	18.5–44	0–0.3	53–78	1.4	–
Stassfurt sylvite	28–40		57.7	0.1–1	–
Dead Sea	1.3	2.2	12	0.8	6

The compn. of Solikamsk carnallite is thus more favorable than that of the Stassfurt material. Solikamsk K salts have the following advantages over the Stassfurt salts: (1) contg. but a negligible amt. of $MgCl_2$, Solikamsk sylvites permit the manuf. of fairly pure KCl by cold crystn., whereas the more expensive hot crystn. method is required at Stassfurt; (2) Solikamsk carnallites, as a result of the favorable geological structure of the ground in which they are mined, can be subjected to an easy mech. sepn. of poor from rich material, whereas the Stassfurt carnallites cannot. B. N.

Origin of the Cretaceous white clays of South Carolina. Fred R. Neumann. *Econ. Geol.* 22, 374–87(1927).—A heavy-liquid and microscopical analysis of some white clays and assocd. sandy clays and sands are given. The deposits were probably formed by the erosion of an uplifted Piedmont area which had been deprived of its Fe by leaching with org. and carbonic acids from a dense vegetational covering. Elliott J. Roberts

The enrichment of bauxite deposits through the activity of microörganisms. George A. Thiel. Univ. of Minnesota. *Econ. Geol.* 22, 480–93(1927).—Leaching expts. on shale, kaolinite, white clay and microcline show a much higher ratio of Al_2O_3 to SiO_2 dissolved when sulfate-reducing bacteria are present than when they are absent. T. considers this to explain the SiO_2-rich mantles of many bauxite deposits. Pyrite is formed by the bacteria, is subsequently oxidized to $FeSO_4$ and H_2SO_4, which leaches the Al_2O_3 from the soil and this is repptd later by hydrolysis. Elliott J. Roberts

Carbon compounds of the magma. Hellmers. *Z. angew. Chem.* 41, 342–3(1928).—From the fact that carbides are not capable of existence in the solid crust of the earth yet probably exist in the magma, it may appear conceivable that the CH_4 which is present in the gases from fumaroles is a product of the action of H_2O on carbides. The temp. of its formation under these conditions would be so high, however, that the gas would be largely dissocd. into its elements, so that it is much more probable that it owes its origin to the reactions $CO + 3H_2 = CH_4 + H_2O$ and $2CO + 2H_2 = CH_4 + CO_2$. CO may well arise in the main from the action of C on CO_2, but the reaction of C with steam must also be taken into account. Examn. of 3 specimens of igneous rocks containing bitumen showed that this latter was a late introduction into the rock, and could not have been formed *in situ*, *e. g.*, by polymerization. No perfectly definite example of the formation of mineral oil deposits directly from the magma has, in fact, ever been observed. B. C. A.

Pneumatolysis as a mineralizer. James Park. *Chem. Eng. Mining Rev.* 20, 224(1928).—Pneumatolysis is defined as the action on rocks by gas evolved from igneous magma. Mass alteration of rocks may occur, accompanied by formation of secondary minerals and of lodes. The shape of the deposit is detd. by the form of the fissures, etc., in the rocks accessible to the volatile mineralizers. The vapors decompose certain constituents of the rock with the production of new minerals, *e. g.*, silicification, gneissization, kaolinization, chloritization, etc. In granites, the feldspars and micas, and in sedimentary rocks, the calcareous constituents, are mainly attacked. Biotite can be changed to muscovite or, in the presence of B_2O_3 to tourmaline; sulfides, CO_2 gas, or carbonates change biotite to chlorite. Consolidation of the magma is followed by the hydrothermal phase in which substances volatile at higher temp. are more stable. The magmatic H_2O changes peridotite to serpentine. Subsequent leaching by surface waters produces local concn. of chromite, Ni and Co as in New Caledonia, or of chromite and Cu as in New Zealand. S. L. B. Etherton

Petrogenetic observations on the andesites of the district of Pilisszentlászló (Comitat Pest, Hungary). Endre Lengyel. *Földtani Közlöny* **55**, 118–27 (Hung.), 309–19(Ger.), (1925 (published 1926); *Mineralog. Abstracts* **3**, 291(1927).—Eruptive rocks are of wide distribution in this dist. and include: biotite-amphibole-andesite, amphibole-andesite, hypersthene-andesite, pyroxene-andesite and andesite-tuffs. Pyroxene-andesite predominates and biotite-amphibole-andesite is of secondary importance. A detailed description is given of these rocks and of their mineral constituents chiefly from a petrogenetic standpoint. The more acidic tuffs are the earliest, and afterwards the rocks are successively more basic. H. G.

Lavas of the Serbian meridional. J. Tomitch. *Compt. rend.* **187**, 133–6(1928).—This study is mainly lithological. Chem analyses by Raoult are reported for the typical rocks: aphyric latite and vitreous latite from Venaz, latite from Dyouriski Vis, shoshonitic basalt from Gradisté and shoshonitic kajanite from Kourel. L. W. Riggs

Geology of the south coast of New South Wales. I. Paleozoic geology of the Moruya district. Ida A. Brown. *Proc. Linnean Soc. N. S. Wales* **53**, 151–92(1928).—The geology is described from the dynamic and lithologic points of view, with 49 references to the literature The order was deposition, folding and faulting, and, toward the close of Devonian time, the injection of a plutonic igneous mass along the zone of weakness. The plutonic mass takes the form of a composite batholith, and forms a complete subalk. or calcic igneous complex, as is proved by a study of the field relationships and the mineralogical and chem. compns. of the various members of the series. The complex consists of 3 main plutonic types, diorite-gabbro, tonalite-granodiorite and biotite-granite, contg. accidental and cognate xenoliths in some parts, and a series of dike rocks ranging from aplitic to basaltic varieties. Chem. analyses of about 20 rocks are given. L. W Riggs

Preliminary statement regarding the diatom "epidemics" at Copalis Beach, Washington, and an analysis of diatom oil. L. B. Becking, C F. Tolman, H C. McMillin, John Field and Tadaichi Hashimoto. *Econ. Geol.* **22**, 356–68(1927). During diatom development the p_H of the sea water is shifted from the normal value of about 8.4 to 8 6 or even 8.8. A study of the chloroform-benzene ext. of the diatoms showed a high % (11.3% of the chlorophyll-free extract) of a S compd. whose m. p. was 115°. The remainder of the ext contd. 65.7% unsaponifiable matter. E. J. R.

Diatoms in western Oregon shales. Hubert G. Schenck. Stanford Univ. *Econ. Geol.* **22**, 565–8(1927).—Analyses of 2 tuffaceous sandy shales from Oregon are given. Elliott J. Roberts

Replacement vs. impregnation in petrified wood. Ruth N. St. John. Cornell Univ. *Econ. Geol.* **22**, 729–39(1927).—Expts. on various petrified woods showed 3 types or stages of petrification: (1) Cell cavities and intercellular spaces have been filled by infiltration of mineral matter but the vegetable tissue of the cell walls is preserved; (2) complete replacement of the plant tissue has taken place; and (3) intermediate between 1 and 2. Silicified samples of type 1 leave a residue of tissue outlining the cell walls when treated with an alc. soln of H_2F_2, while those of type 2 dissolve completely. Elliott J. Roberts

Origin and mineral constitution of the Late Tertiary fossil wood of Burma. Harbans Lall Chhibber. *J. and Proc. Asiatic Soc. Bengal* **23**, No. 1, 13–26(1928).—The theories of W. Theobald and of Murray Stuart with reference to the formation of petrified wood are not accepted. Chalcedony and microcryst. SiO_2 generally, and opal occasionally, form the bulk of the specimens. Calcite and siderite are occasionally present. In exceptional cases quartz has been deposited in the broad bundles of the vascular tissues while the parenchymatous tissue has been replaced by Fe and Ca carbonates. "The origin of fossil wood is due to colloidal material associated with waters laying down the deposits in which it is preserved." The lithology of the Irrawaddy series supports such an origin Both mech. and chem. weathering helped in the formation of colloids. Some of the colloidal material seems to have been changed into crystalloidal afterwards. Fresh-water desert conditions are favorable to the formation of fossil wood, especially when alkalies are present in abundance to decompose the silicates and liberate colloidal SiO_2 to be deposited in the woody tissue. L. W. Riggs

Great Bahama Bank. Marine sediments. Richard M. Field. Princeton Univ. *Am. J. Sci.* **16**, 239–46(1928).—A geological reconnaissance is reported of the west coast of Andros Island and of the Great Bahama Bank. L. W. Riggs

Geographic and oceanographic research in Indian waters. II. Nature of the sea-bed and of the deep-sea deposits of the Andaman Sea and Bay of Bengal. R. B.

SEYMOUR SEWELL. *Mem. Asiatic Soc. Bengal* **9**, No. 2, 27–49(1925).—The $CaCO_3$ content in 28 samples of ocean bottom mud or ooze from the south central portion of the Bay of Bengal averaged 45.4%. The depths of these samples ranged from 1427 to 3655 m. Detns. by Alcock in the northwest regions of the bay averaged 9.1% in 27 samples. In general, in passing from shallower to deeper waters there is at first a decrease in the percentage of $CaCO_3$ in the bottom mud. This is followed by an increase and again by a second decrease. The possible relations between the quantity of $CaCO_3$ deposited and the quantities of SiO_2 and CO_2 present in the water, the depth and the movement of ocean currents are discussed. L. W. RIGGS

Recent investigations in geochemistry. ERICH HERLINGER. *Z. angew. Chem.* **41**, 249–54(1928). E. H.

Radioactivity of the gases and water of the Ukhta oil-bearing region and of medicinal mud and brine from the salt lake of the Tinakee Station (CHEREPENIKOV) **3.** Constitution of the silicates (WAHL) **6.** Constitution of aluminosilicates, conditions of their formation, and transformation in soil (WAHL) **6.** Mineral black (LANGTON) **26.** Researches on silicates (CHERBULIEZ, ROSENBERG) **6.** Chemical and economical considerations concerning wood and coal (BERGIUS) **21.** The origin of coal (OBST) **21.** Panuco oil field, Mex. KRAUS, EDWARD HENRY AND HUNT, WALTER FRED: **Mineralogy.** An introduction to the study of minerals and crystals. 2nd ed. revised. New York: McGraw-Hill Book Co., Inc. 604 pp. $5.00. Cf. *C. A.* **15**, 493.

9—METALLURGY AND METALLOGRAPHY

D. J. DEMOREST, R. H. ABORN

Contributions to the question of heat changes in metallurgical reactions. C. SCHWARZ. *Arch. Eisenhüttenwesen* **1**, 525–6(1928).—The heats of metallurgical reactions using C, tabulated in "Investigations on the Available Heat of Siemens-Martin Fusions" (*Ibid* **1**, 33–40(1927)), must be revised, because of the new work of Roth in the 1927 supplement of Landolt-Börnstein's "Phys.-Chem. Tables." The most reliable values of heats, at present obtainable for use in Siemens-Martin practice, are tabulated. J. BALOZIAN

Three stages of the development of French siderurgy. LOUIS BARADUC-MULLER. *Science & industrie* **12**, No. 168, 33–8(1928). E. H.

Efficiency in hydraulic current classification of finely crushed ores. T. GRAHAM MARTYN. *J. Chem. Met. Mining Soc., S. Africa* **28**, 283–302(1928).—A discussion of the general problem of classification and of the Martyn classifier. The paper is divided into 12 sections: (1) the problem of classification—Cornish Sn slime; (2) the sepn. of slime from heavier materials; (3) early machines and processes; (4) the fall of particles—hindered and unhindered in liquid; (5) concentrates made from classified products; (6) slime sepn. before classification; (7) sepg. fine particles first and the heaviest particles last; (8) the problem of slime settlement; (9) special form of separator; (10) Martyn's perfected slime classifier; (11) Martyn's sand classifier; (12) Martyn's complete machine. The evolution of M.'s classifier is indicated by sketch and description and details are given of the perfected app. The app. should be widely applicable for uses such as: washing and classifying all *sands used in concrete* work; for the purification of *clays* and *paints;* for the washing of pulverized carbonaceous *fuel;* for the removal of shale and pyrites from *coal;* for the grading of *abrasives* such as corundum; and for the washing and grading of sand in the *filter beds of water works* and *sewage-treatment works*. It is possible that the app. might be used in the sepn. and *washing of crystals* sol. in water, in which case water is replaced by a liquid in which the crystals are insol. The app. permits continuous classifying, into as many different grades as desired, of mixed particles of varying size and sp. gr., classification being according to their unhindered rate of fall in liquid. W. H. BOYNTON

The working and behavior of zinc-bearing iron ores, particularly the Meggener roasted pyrites, in the blast furnace. MAX PASCHE. Saschsischen Bergakademie, Freiberg. *Archiv Eisenhüttenwesen* **1**, 387–403(1927).—This ore is difficultly smelted

in the Zn muffle because of its high Fe content, and in the blast furnace because of its fineness, and its Zn and S content. Two processes are developed for smelting this type of ore. In the first by sintering in a Dwight-Lloyd machine (preferably) or in a revolving-furnace the ore is caked; 90–95% of the S, only 6–7% of the Zn, and over 1/2 the Pb and As are removed. The sinter may then be smelted directly in the blast furnace providing the sinter is porous, the charge and coke are dry, the furnace is constructed of suitable materials, and the throat gases leave at the highest possible temp. By mixing NaCl (50% in excess of that required to form $ZnCl_2$) with the sinter, the vaporization of Zn is aided and the deposition of Zn deposits in the furnace and in the flues is prevented. In both cases the Zn compds. volatilized during the smelting are collected and the Zn is recovered. A method is given whereby the SO_2 gases formed in the sintering may be converted into H_2SO_4. In the second process, the roasted pyrites is smelted in the blast furnace (without sintering), ferro-Mn being added in sufficient quantity to produce a liquid slag. By blowing compressed air through the melt during the smelting, the metal obtained contains 30–38% Fe and 6–7% Mn, the S being completely burned, and the Zn, Pb and As vaporized. S and Zn are recovered as before.

J. BALOZIAN

Cyanide extraction of gold and silver associated with arsenic and antimony in ores. EDMUND S. LEAVER AND JESSE A. WOOLF. Bur. Mines, *Tech. Paper* **423**, 52 pp.(1928).—Ores in which Au and Ag are assocd. with As and Sb are usually refractory to CN treatment. Results of this investigation show what to expect with CN treatment in cold and hot solns. and effect of roasting at various temps. A short-time roast for approx. 30 min at 450° seems to result in max. CN recovery of Au and Ag assocd with As and Sb. The usual high-temp. roast at 600° and above results in the formation of arsenates and antimonates, which interfere with soln. of Au and Ag. The addn. of CaO before CN treatment prevents excessive loss of CN and fouling of soln.

H C PARISH

Condenser materials and blue powder in zinc smelting. RUSSELL W. MILLAR. *Mining & Met.* **9**, 395(1928).—Expts. have proved that when pure Zn vapor and pure CO are brought together at partial pressures of 0.03 and 0.5 atm. and temp. of 650° the reaction, Zn gas + CO = Solid ZnO + C, takes place extremely slowly in the absence of an active catalyst. No increase in rate of reaction was noted at 850°. The presence of clay contg. Fe promoted the reaction at a high rate, Fe_2O_3 apparently acting as a catalyst. M. suggests that an investigation of the relation between Fe content of clays and the rate of formation of chem. blue powder in condensers made from the clays would elucidate one cause of inefficient condensation of Zn in the present app.

H. C. PARISH

The retreatment of Comstock tailings. E. S. LEAVER AND J. A. WOOLF. Bur Mines, *Repts. of Investigations* No. **2883**, 7 pp.(1928); *Eng. Mining J* **126**, 448 50.—The approx. metal content of Douglas tailings from Comstock ores is 2.8 oz. Ag, 0.055 oz. Au, 0.5 lb. Hg and 0.12 oz Cu. Gravity concn., straight cyanidation, a preliminary acid wash followed by aeration-oxidation were all unsuccessful, the latter because of added cost of preliminary acid treatment. Flotation tests resulted in recoveries from 21.8 to 41.7% of Au from 18.7 to 38.8% of Ag and 50% of Hg. Results of CN tests on Douglas tailings with regeneration of CN by Na_2S-H_2SO_4 pptn. method show extns. of 83.7–86.4% Au, 85.7–87.4% Ag and 42.6–52.5% Cu and regeneration of approx. 78% of CN. An extn. of 80–88% Au and 82.5–88.0% Ag from flotation tailings was obtained by the same method as well as a CN regeneration of 62.6%. H. C. PARISH

Salt roasting and cyaniding at Achotla, Mexico. I, II. Plant operations and results. E. R. RICHARDS. *Eng. Mining J.* **126**, 325–9, 370–5(1928).—A short history of the development of the process, and a description of the milling plant of the Achotla plant. Exptl. lab. results of salt roasting led to the construction of a 10-ton-per-day plant which embodied the following: (1) a complete crushing and screening plant, (2) a full-size standard Holt-Dorn roasting furnace, (3) calcine crushing rolls, (4) leaching vats, (5) Cu pptn. boxes to remove Ag from the first water wash, (6) Zn boxes for cyanide pptn., (7) storage tanks for cyanide solns., (8) fans, pumps and complementary app., (9) steam engines and boilers for power use, and (10) tower for making acid and storage tank for acid. The plant gave: (1) satisfactory Ag and Au extn., (2) easy and consistent operation, (3) low cyanide consumption with proper acid washing, (4) with low protective alky. in the cyanide effluent elimination of Pb in the ppt., (5) by agitating the pregnant soln. with air and a slight excess of lime, the $CaSO_4$ could be dropped and settled out in a settling tank and not enter the Zn boxes. Oxide ore is crushed to 8–10 mesh, mixed and roasted; acid is made from the roaster gases with which to leach the calcines. Leaching the calcines with water and

acid to remove base metals and cyanicides is followed by treating of the pregnant soln. with lime and filtering to clarify the soln. properly, pptg., the usual Merrill-Crowe process being indicated. Salt is crushed in a sep. plant. A flow sheet shows the roasting and leaching treatments and a plan of the plant. The chemistry of the process and the difficulties in starting the plant are outlined. Au extn. is 92–96% and Ag extn. 82–88%. The acid wash has an acid content of 0.25–0.35% by wt.—0.1–0.15% is SO_2 and the remainder HCl. About 4–5 tons of acid is used per ton of ore. A short water wash removes the acid from the charge. Salt is the most expensive reagent, costing $2.07 per ton of ore. Next comes cyanide. Lime consumption is 50–60 lbs. per ton of ore, and Zn dust consumption is close to theoretical requirements. Power consumption is about 21 kw.-hr. per ton of ore treated and labor cost about 50 c. per ton including mill overhead. W. B. H.

Forced heating of air blasts for blast furnaces. Fr. L. Clerf. *Chimie et industrie* **Special No.**, 202–16(April, 1928).—A general discussion, largely mathematical, of the operation of modern blast-heating equipment. A. Papineau-Couture

The mode of operation of blast-furnace stoves with special reference to the Pfoser-Strack-Stumm process. H. Illies. *Feuerungstech.* **16**, 189–90(1928).—In this process there are only 2 stoves in action per furnace, each 1 hr. on air and 1 hr. on gas. The efficiency is about the same as in the ordinary process. A proposal to use 3 stoves for 2 furnaces is promising. Ernest W. Thiele

Temperature measurements in the open-hearth furnace. B. M. Larsen. *Fuels and Furnaces* **6**, 1163–8(1928).—The best practice in detg. flame temps., slag and wall surface temps., bath temps. and furnace control by temp. measurements is described Flame temps. obtained by the disappearing-filament pyrometer are best made by adjusting the filament to disappear when the flame is brightest. The radiation measured from the surface of the slag or from the roof may be from 30° to 200° F. too high in consequence of heat reflected from the flame above the slag. Shutting off the flame a few seconds before making the reading obviates this error. The roof temp. of a basic furnace should not rise above 2975° to 3025° F., as deterioration by fusion of the silica brick is rapid above this temp. range. Slag-surface temps. detd. by means of an optical pyrometer measure fairly correctly the bath temp. if made when the gas is turned off. Thermocouples buried in the wall of the refractories may be used to obtain temp. gradients. Gas temps are best ascertained by drawing a rapid stream of the gas over the hot junction of the thermocouple. Pyrometer control of the checker-chamber and melting chamber permits more efficient operation of the furnace and affords an opportunity to protect the roof from too high temps. J. W. Shipley

Effects attributed to oxygen and to so-called de-oxidizers in the manufacture of open-hearth and converter steels. J. Seigle. École de la Métallurgie et des Mines, Nancy. *Chimie et industrie* **Special No.**, 345–61(April, 1928).—A crit. review of recent contributions to the subject. A. Papineau-Couture

The mode of operation of cupolas. J. Follman. *Feuerungstech.* **15**, 308(1927).—F proposes to separate the melting of Fe into 2 parts—melting at the lowest possible temp. in the cupola proper, and subsequent superheating with gas or oil in a hearth. This would have the advantages of the duplex process and be cheaper. E. W. T.

The Kühn regenerator system. Thaler. *Feuerungstech.* **16**, 123–5(1928).—This open-hearth regenerator is 16 m. long, as against a normal 4 m. The free area diminishes toward the end, to correspond to the decreased gas vol. The first section has a sloping bottom, to get rid of slag. The exit temp. is 250° against the usual 800°. In addn. to the heat economy, the capacity and life of the furnace are much increased. Ernest W. Thiele

Cleaning blast-furnace gas. Arthur J. Boynton. *Am. Inst. Mining Met. Eng. Tech. Publ.* No. **125**, 25 pp.(1928).—See *C. A.* **22**, 2131, 2533. W. H. B.

Blast-furnace gas indicates conditions. Wallace G. Imhoff. *Iron Age* **122**, 203–4(1928).—When the gas burns with a heavy bright yellow flame it shows the presence of a large amt. of extremely finely divided C particles. A large quantity of gas shows that conditions are such as to liberate large quantities of C for burning gas. Molten Fe tends to throw off C rather than to absorb it. This is shown by the thick mushy state of the Fe. C gives fluidity to the Fe and if too much has been removed from it the Fe is thick and pasty. The S is low in the Fe, while it is high in the slag. Removal of too much C as graphite builds up the hearth and holds the Fe in the furnace, resulting in high CaO, a cold hearth "off Fe" and low production. For high production and good, regular driving, the fusion zone should be down in the hearth. This gives a strong, yellow gas with high B. t. u. As the hearth cools the character and B. t. u.'s of gas change. The vol. of free S increases, SiO_2 reduced decreases, C tends to

be absorbed by Fe as combined C, the vol. of gas decreases and its heating value becomes low. The yellow gas gradually turns to orange, then to deep blue and finally to crimson red and violet. The vol. decreases, necessitating the use of coal at boilers to keep up steam. H. C. Parish

Studying gas to learn conditions. Wallace G. Imhoff. *Iron Age* **122,** 393–4 (1928).—Excess of C in gas gives a hot, yellow gas while a shortage gives a thin, cold, blue gas. A bluish purple gas is assocd. with a falling of the hearth temp. and a dropping of the fusion zone into the hearth. The Fe, when cast, instead of being a bright yellow color is orange. It glistens and shines because of a supersatn. of C. When cast the excess C in the Fe, under reduced pressure, is thrown out in the form of graphite Production depends primarily upon the rapidity of reduction of the Fe ore to metallic Fe and the smooth rapid driving of the furnace. Some of the conditions which give rapid driving are low fusion zone, moderate use of CaO, high hearth temp., proper wind, proper stove heat control, clean raw materials, right burden and good condition of equipment. H. C. Parish

Apparatus and methods for measurement of the Hertzian hardness. R. Esnault-Pelterie. *Engineer* **146,** 180 1, 196–7(1928).—The common methods of detg. hardness, *viz., sclerometric, rebound, Brinell, pendulum* and *Hertzian methods,* are discussed. In the proposed method, two spheres are subject to const. and successively increased pressures. One sphere has a thin coating which renders the zone of contact visible after each compression. The diam. of the circle of contact is plotted as a function of the force F. In general $d^3 = nF$ until the elastic limit is reached, when a cusp appears in the curve Typical results are given. D. B Dill

The classification of fractures in the testing of materials. Marcel Koenig *Chimie et industrie* Special No., 375–81(April, 1928).—A discussion of the aspect of the fracture of test pieces in tensile strength tests, which is affected by the mode of deformation, nature and condition of the metal, presence of localized flaws, direction of the deformation with respect to that of the fibers of the metal, the presence or absence of inclusions forming lines in the metal, and also possible play in the jaws of the machine or improper alignment thereof. Four different classifications of fractures are given, and it is suggested that they might be used as a basis for a universal classification which should be adopted. A. Papineau-Couture

Making low-carbon iron. C. R. McGahey. *Foundry* **56,** 723, 727(1928).—Coke contg. as much as 8.84% ash and 0.597% S may be good for cupola melting if strong enough. In making low-C Fe or semi-steel, the metal tapped first is of comparatively low strength, for a uniform mixt. is not obtained until the first charge is used up. For a chill test, a block 1½ by 3 in. is recommended, with the 1½ in. face cast against a chill at least 3 or 4 in thick. A few typical analyses are discussed on Fe that gave breaking strengths of 1800 to 2200 lbs. for a 1 by 1 by 24 in. bar. Geo. F. Comstock

The chief alloy steels and their uses. Persoz. *Aciers spéciaux* **2,** 233–7, 302–4, 354–6(1927); *Chimie et industrie* **20,** 52–3(1928).—It is considered that in alloy steels, as in C steels, only 3 phases can exist in equil.: ferrite or α phase; cementite; austenite or γ solid soln Known facts would indicate that these phases are the same as the corresponding phases of C steels. In practice, if only the heat treatment of an alloy steel of const. compn. is considered, such a steel may be considered as consisting of 2 independent constituents: a complex Fe alloy (complex ferrite) and a complex carbide (complex cementite), these 2 constituents being undecomposable within the limits in which the steel is studied. The equil. diagrams of alloy steels are thus analogous to those of C steels (Roozeboom diagrams). Grenet has suggested grouping alloy steel in 4 classes, according to their transformation pts. on heating and on cooling (best detd. by means of the Chevenard dilatometer): (1) Steels in which the transformation pt. on slow cooling is practically the same as on heating. C steels and most of the ordinary Si, Ni and Ni-Cr structural steels belong to this group. (2) Steels in which the transformation pt. on slow cooling (100° in 30 min.) is practically the same as on heating, and in which the transformation pt. on moderate cooling (about 100° in 10 min.) is considerably lower than on heating. This group includes high-speed (Cr, W and certain Cr-Ni) tool steels Some of these steels do not undergo any transformation between 300° and 600°; if the metal is cooled very slowly, the transformation takes place below 600°; if it is cooled more rapidly, it remains stable until it falls below 300°, even if it remains a long time at 300–600°. It follows that in order to harden such a steel it need only be cooled fairly rapidly to 550°; the transformation will then take place below 300° and the metal will be hardened. (3) Steels in which the transformation pt. on cooling differs greatly from that on heating. even when cooling is very

slow. The most important members of this group are Ni-Cr steels with relatively high Ni and Cr contents. (4) Steels in which the transformation pt. on cooling is below atm. temp., the chief ones being high-Ni steels (with or without Cr or Mn) and high-Mn steels. The compn. and uses of the most important alloy steels are given. A. PAPINEAU-COUTURE

Recrystallization of cast steel after hot working. W. HEIKE AND F. WESTERHOLT. Freiberg i. Sa. *Z. anorg. allgem. Chem.* **174,** 244–56(1928).—The cast steel examd. had the compn. 0.28% C, 0.60% Mn, 0.27% Si, 0.026% P, 0.020% S, and gave the following critical points: Ac_{2-3} 807.5°, Ar_{3-2} 758°, Ac_1 739°, Ar_1 709°. Castings of this steel in the form of cylinders, 20 mm. in diam. and length, were subjected to various degrees of compression after having previously been heated to 700–920°, the object being to eliminate the *Widmanstättian structure* and bring about recrystn. with small grain size. Examn. of the structure after compression shows that the large columnar crystals at first become subdivided into smaller grains having a directional orientation. With further change due to higher heating or greater compression, this directional orientation is destroyed and the grain structure becomes irregular. Subdivision of the Widmanstättian structure into fine grains commences at about 700° with about 35% compression. With temp. below this, recrystn. does not occur, regardless of the amt. of compression. The greatest alteration in grain structure occurs between 775° and 825° with 10% compression, between 760° and 810° with 20% compression, between 750° and 790° wit h 40% compression, and between 740° and 780° with 50% compression. Places in the castings rich in P, lag behind the others in the recrystn. process. H. STOERTZ

An investigation of abrasion in carbon steels. MASUHIRO SUZUKI. Jap. Govt. Rys., Tokyo. *Sci. Repts. Tohoku Imp. Univ.*, 1st Ser., **17,** 573–638(1928).—Steels contg. 0.11 to 0.88% C were tested for abrasion resistance by rotating the end of one tubular specimen against the end of another under a controlled pressure. The friction between the two was detd. by measuring the force required to keep the undriven specimen from revolving. Since the coeff. of friction is an important factor controlling the amt. of abrasion, measurements of the latter were made only after this coeff. had become const. by elimination of surface irregularities. Changes of temp., which were not over 50°, were disregarded. A large no. of tests with different combinations of specimens, loads and speeds, are recorded and discussed. The 0.11% C steel showed under some conditions less abrasion than the 0.22% C steel owing to slight differences in friction and work-hardening. Otherwise the abrasion was less with higher C up to 0.7 to 0.8%; and it also decreased as the condition of the steel changed in the following order: as rolled, annealed, sorbitic, troostitic and martensitic. The abrasion increased linearly with the work done, and parabolically with the coeff. of friction; it was affected slightly by velocity and pressure. A formula is derived, and constants for different structures are given so that the abrasion between two steels of 0.34 to 0.88% C can be computed if the abrasion between each of them and a standard is known. The structures of the specimens used are illustrated by photomicrographs. G. F. C.

New plates and powders for welding iron and steel at low temperature. PAUL DUFOUR. Conservatoire Nat'l des Arts et Métiers, Paris. *Chimie et industrie* Special No., 343(April, 1928).—Forge-welding of Fe can be carried out successfully at 1400°, just below the m. p., but with steel the temp. should not exceed about 1000°. This can be obtained with excellent results by using Fe filings which have been very highly carburized to lower their m. p. Such filings have the added advantage that they create a reducing atm. in the immediate neighborhood of the weld and thus prevent oxidation of the steel. A. PAPINEAU-COUTURE

Self-hardening property of chromium steel. ICHIJI OBINATA. *Memoirs Ryojun Coll. Eng.* **1,** 145–66(1928).—Steels were studied with from 7.1 to 18.6% Cr and 0.21 to 0.30% C in both the annealed and the quenched condition. In the annealed condition the effect of the Cr is to raise the Ac_1 point and to lower the Ar_1 point at the normal rate of heating. The A_2 magnetic change point is lowered about 7° for each addn. % of Cr. The stable structure of O.'s series of annealed specimens was pearlitic and probably consisted of a solid soln. of Fe and Cr and a Cr carbide with a little Cr as a solid soln. As there exist only 2 phases in the annealed specimens, the A_1 point of this steel does not occur at a const. temp. but varies according as the carbide dissolves in a solid soln. at that temp. From the microstructure of the quenched specimens, it was proved that, at certain ranges of temp., there exists the γ-phase throughout the series of specimens. The carbide change point on heating, taken from the quenched specimens, was lower than that taken from the annealed specimens; the difference in the temp. of the Ac_1 point became larger as the quantity of Cr increased. The quantity

of heat absorbed at the Ac_1 point, when the quenched specimens were tempered, was smaller than that when the annealed specimens were heated; the difference became larger as the quantity of Cr increased. The soaking time, under which the specimens were exposed at 980°, had no influence on the position of the Ac_1 point or on the quantity of heat absorbed at that temp. Neither the annealing nor the quenching of the specimens had any appreciable influence on the A_2 point. The lowering of the carbide change point on cooling, which imparts the self-hardening property to the steel, is due to the retardation of the deposition of the re-formed carbide from the supersatd. solid soln. C. J. West

Rare metals. Anon. *Metallurgist* (Suppl. to *Engineer* **146,** No. 4) 98-9(1928).—Detailed studies of rare metals may prove of practical importance. Study of Be has indicated possible com. use as an alloy with Cu and discovery of new sources has followed. D. B. Dill

The superheating of aluminum. J. Suhr. Cie. Alais, Froges et Camargue. *Chimie et industrie* Special No., 392-6(April, 1928).—Superheating of Al to over 950° (max. used in the tests 990°) completely eliminates any Na which might accidentally be present and also any inclusions from the electrolytic bath which might have been held in the Al due to rapid cooling when it was poured. When Al having poor mech. properties is remelted and held at 730-830° for 3 hrs., there is but little or no improvement in properties; but if it is held at 900-35° for the same length of time and then poured at 730°, the properties are greatly improved and become normal. Al which had been improved by superheating to 935° was poured at temps. of 790°, 850°, 910°, 940° and 990°, the rates of pouring being decreased as the temp. was increased, and in each case part of the metal was allowed to cool and was poured at 730°. The mech. properties (elastic limit, tensile strength and elongation) were identical for all pouring temps., and in no case were blowholes observed. Though the tendency of Al to absorb gases increases with temp. of melting, this can be entirely offset in practice by increasing the time taken for pouring as the temp. increases, so as to allow the dissolved gases to escape during the cooling period. A. Papineau-Couture

The spectrography of alloys by means of x-rays. M. H. Weiss. *Bull. soc. chim.* **43,** 697-711(1928).—A review. A. J. King

Aluminum alloys. Zay Jeffries. *Mech. Eng.* **50,** 684-6(1928).—Standard alloys of Al for sand casting, pressure die casting, permanent-mold work and forgings are tabulated, showing compn., tensile strength, elongation and Brinell hardness no. The same phys. properties of four alloys cast in sand and permanent molds are shown after heat-treating. Downs Schaaf

Aluminum and aluminum alloys in the chemical and allied industries. J. Dornauf. *Z. angew. Chem.* **41,** 993-1001(1928). E. H.

The welding of light alloys. J. Isoré. *Aciers spéciaux* **2,** 357-63(1927); *Chimie et industrie* **20,** 56(1928).—Welding of Al presents the drawback of greater corrosion at the weld, which has been shown to be due to impurities and to a modification of the structure of the metal at the weld, while the flame itself has no chem. action when excess of C_2H_2 is present. Welds which are to be exposed to acid fumes, or even only to sea air, should be prepd with the very highest-grade materials. In welding Al, strains and deformations are best avoided by heating the whole piece to be welded to about 400°; a non-oxidizing flame should be used, and the size of the blow-pipe should be increased very rapidly with the thickness of the sheets to be welded. The oxy-acetylene welding of duralumin is not impossible, but is a delicate and expensive operation. Mg can be welded with the same chloride, fluoride and alkali bisulfate fluxes as for Al, but NH_4Cl and MgF_2 should also be added. A. Papineau-Couture

(The mechanical and physical properties of) light and ultra-light alloys in the working temperature range of airplane motors. C. Grard. Service Technique et Industriel de L'Aéronautique. *Chimie et industrie* Special No., 382-5(April, 1928); cf. G. and Villey, *C. A.* **22,** 751.—The tensile strength, elastic limit, elongation, Brinell hardness and d. of light (Al and its alloys) and ultra-light (Mg and its alloys) metals are tabulated, and the elec. and thermal conductivities of Al and Mg contg. increasing amts. of Cu (up to 12%) are plotted. *Conclusions.*—Cast Al contg. 12% Cu is at present the standard alloy for airplane motor pistons, and experience has shown its behavior at the working temp. (330-20°) to be satisfactory. Forged Mg contg. 4% Cu has better mech. and thermal properties than the alloy at present in use, and also a considerably lower d. (1.86 instead of 2.95) and the disadvantage of having to forge it (the mech. properties of the cast alloy being inferior) would be more than compensated by the benefits above mentioned. Two forged alloys (Mg 94, Cu 4, Al 2; Mg 94, Cu 2, Al 4%) have remarkably good mech. properties, but a lower thermal cond., and would

be suitable for parts working at a lower temp. (*e. g.*, crank-cases) on account of their lightness, hardness and resistance to shock. A. Papineau-Couture

Die-casting alloys of low melting point. T. F. Russell, W. E. Goodrich, W. Cross and N. P. Allen. Sheffield Univ., England. *J. Inst. Metals* (advance copy), No. 473, 15 pp.(1928).—Two series of Zn-base alloys were investigated, one contg. Cu up to 3.7%, Sn up to 22% and less than 1% Al, and the other contg. Al up to 4.6% and Cu up to 7%. Flat die-cast tensile test specimens showed 50% greater tensile strength when the shoulder radius was 2 in. than when it was 1/4 in. The size of gate and pouring temp. (if not over 80° above the mushy stage) had little effect on the tensile strength. Slow operation of the lever of the casting machine gave slightly stronger and denser castings. Tensile strengths up to 23 tons per sq. in. were obtained, axial loading being essential. For hardness testing, the Vickers diamond pyramid machine was found more reliable than the Brinell or Rockwell machines. The hardness of these die-castings had no relation to the strength. Transverse results were more dependent on porosity. Comparative brittleness may be estd. from twisting tests, the alloys contg. Al being better in this respect than those contg. Sn. The addn. of Ni increased casting difficulties, but Cd was a benefit. Changes in dimensions of Zn-base die-castings on aging were variable, even with const. shape of casting. The Al-Cu-Zn alloys did not change more than the Sn-Cu-Zn alloys. Changes in air were very slow. In steam, chem. action caused more rapid changes. There was first a contraction, different for different castings, and then a more const. expansion. Part of the expansion was due to surface oxidation, and part to constitutional changes and intercrystalline oxidation. Porosity increased the growth. Rods of various steels and cast Fe were held in molten Zn and the reduction in diam. measured. Cast Fe and high-C steel were corroded more than soft steel. Calorizing gave perfect protection, but Ni plating and Cr plating did not protect. Some of the Ni-Cr steels were more resistant than plain steels. Geo. F. Comstock

The equilibrium diagram of the copper-silicon system. Kanji Matuyama. *Sci. Repts. Tôhoku Imp. Univ. 1st Ser* 17, 665-73(1928).—Thermal analyses, microscopic examn. and elec. resistance measurements were made on 30-g. specimens of Cu-Si alloys covering the entire system, and a new equil. diagram up to 30% Si is presented. The 4 branches of the liquidus correspond to the sepn. of 3 solid solns. and Si. A max. occurs with 12.9% Si at 865°, indicating a compd., Cu_5Si. Eutectics occur at 10% Si and 828°, and at 17% Si and 805°, the latter appearing in all alloys between 14 and 100% Si. A peritectic reaction occurs at 860° in alloys between 5.9 and 7.9% Si. The app. used for the detn. of elec. resistance is illustrated and described. The soly. of Si in Cu was found to be 5.9% at 800° and 4.9% at room temp. Beta formed by the reaction at 860°, decomposes at 795° into a eutectoid, contg. 8% Si, of gamma and alpha. Gamma or the compd. Cu_6Si (8.17% Si) is also formed at 800° by reaction between beta and delta, and has an allotropic change at 738°. Delta, based on Cu_5Si, contains 11.5 to 14% Si at 800°, but only 12.2 to 13.2% at room temp. Twelve photomicrographs of typical structures are presented and discussed. G. F. C.

Silicon-aluminum cast alloys. J. Dornauf. Frankfurt A. M. *Z. Metallkunde* 20, 289-92(1928); cf. *C. A.* 22, 210.—The influence of added Si, Fe, Mg, Mn, Cu, Zn, Sn and Sb upon the Al-Si eutectic alloy "silumin" was studied. In the Al-Si alloy as the Si content rises the tensile strength increases until with 12-14% Si it reaches the max. of 18-23 kg./sq. mm. At this point the elongation is 5-10%. The eutectic point lies at 12.8% Si, and in this vicinity the best physical properties are obtained. Above 14% Si there is a rapid loss in tensile strength and increase in hardness. Up to an Fe content of 0.8% the tensile strength is not appreciably affected, but with Fe from 1.0 to 1.5% this falls to under 15 kg./sq. mm., and elongation is less than 1%. Less than 1% Mg exerts considerable influence upon the mech. properties of silumin. With 4% Mg tensile strength is about 14 kg./sq. mm. and elongation about 1%. Ca exerts about the same effect as Mg. Mn content of 0.1 to 0.4% has a beneficial effect upon the refining process. Above 1% tensile strength and elongation fall, being about 14 kg./sq. mm. and 2.5% at 3% Mn. With 5% Zn tensile strength is 16-17 kg./sq. mm. and elongation 3%. Addition of 0.6-0.8% Cu to silumin increases the dynamic elastic limit about 80%, resulting in an increase in fatigue strength. With 2% Cu tensile strength is about 16 kg./sq. mm., elongation about 1%. Sn has a very unfavorable effect. With 0.2% tensile strength is only 16 kg./sq. mm. and elongation 2-3%. With 4% Sn tensile strength and elongation are about 13 kg./sq. mm. and 2.5%. Sb, Ti and Ni have about the same effect as Sn. About 5000 commercial samples of silumin are tested, 75% showing tensile strength of 18 kg. per sq. mm. and over. In the refinement of Al-Si alloy, the addition of a small quantity of Na is helpful. H. S.

Shrinkage and surface strains in hard-drawn wires of copper, aluminum, aldrey and aludur. H. Bohner. Lautawerk (Lausitz). *Z. Metallkunde* **20**, 286-8(1928); cf. *C. A.* **22**, 2543.—The behavior of wires of Cu, Al, aldrey and aludur under the influence of heat treatment was studied. Apparatus is described for detn. of thermal expansion. As the temp. is raised a point is reached at which the sample commences to shorten if the heating is continued, and when it is cooled a permanent shortening has occurred which is greater the higher the temp. of heating has been and the longer the heating has continued beyond the point of max. expansion. For Al, aldrey and aludur shortening commences at 200-250°, for Cu at about 500°, for bronze at about 360°. The max. expansion for Cu is about 0.9%, for bronze about 0.8%, for Al about 0.5%, for aludur about 0.7%, for aldrey about 0.56%. The permanent contraction obtained for Cu is about 0.3%, for bronze about 0.25%, for Al about 1.4%, for aldrey about 1.0%, and for aludur about 1.0%. Shortening is attributed to shrinkage of the surface of the wire as a result of the effect of surface strains, which at certain temps. become greater than the strength of the wire. Recrystn. is produced with the formation of large grains and a reduction likewise of elec. cond. H. Stoertz

The binary systems: cadmium antimony and cadmium lead. E. Abel, O. Redlich and J. Adler. Tech. Hochschule, Wien. *Z. anorg. allgem. Chem.* **174**, 257-68(1928).—In the binary system Cd-Sb, 2 compds. exist CdSb and Cd_3Sb_2, but the latter is unstable and on cooling the melt is transformed into CdSb. With alloys above 33 atomic % Sb, this transformation is indicated by sudden increases in temp. as the alloy is cooled, while with less than 33 atomic % Sb this self heating is not evident and the transformation to CdSb is slower. Between 40 and 50 atomic % Sb a eutectic of CdSb and Cd exists. In the system Cd-Pb it is shown that Cd and Pb are practically insol. in one another in the solid state. Values are given in a table for the log of the activity coeff. $\gamma = a/N$, in which N = molar fraction. Thus with $N_{Cd} = 5$, $\log \gamma_{Cd} = 0.819$ and $\log \gamma_{Pb} = 0.008$, with $N_{Cd} = 25$, $\log \gamma_{Cd} = 0.471$ and $\log \gamma_{Pb} = 0.060$; with $N_{Cd} = 50$, $\log \gamma_{Cd} = 0.243$ and $\log \gamma_{Pb} = 0.195$; with $N_{Cd} = 75$, $\log \gamma_{Cd} = 0.087$ and $\log \gamma_{Pb} = 0.465$; with $N_{Cd} = 95$, $\log \gamma_{Cd} = 0.008$ and $\log \gamma_{Pb} = 0.989$. These values are in good agreement with W. N. Taylor's. H. Stoertz

The ternary system: lead-antimony cadmium. E. Abel, O. Redlich and J. Adler. Techn. Hochschule, Wien. *Z. anorg. allgem. Chem.* **174**, 269-80(1928).—The ternary alloys were prepd. by adding various quantities of Pb to 6 previously prepd. binary Sb-Cd alloys. The system (examd. thermally and micrographically) can be divided into 2 ternary half systems sepd. by a quasi-binary section Pb-CdSb, on one side of which only Sb, Pb and CdSb are present as solid phases, and on the other side of which only Cd, Pb and CdSb are the solid phases. The quasi-binary section has a compn. in atomic % of 85.6 Pb, 7.2 Sb and 7.2 Cd located at 275°, while the Pb, Sb, SbCd eutectic is located at 242°, with the compn. in atomic % of 80.1 Pb, 17.7 Sb, 2.2 Cd and the Pb, Cd, SbCd eutectic is located at 236° with the compn. in atomic % of 68.2 Pb, 3.8 Sb and 28.0 Cd. H. Stoertz

Volume change of manganese during solidification. Yoshiharu Matsuyama. *Bull. Inst. Phys. Chem. Research (Tokyo)* **7**, 731-3, English Ed. **1**, 65.—The vol. change of metallic Mn accompanying solidification was measured by means of a thermobalance. It was found that Mn contracts during solidification by 1.7% of its vol. E. J. C.

The variation of the standard of silver and copper alloys fused in contact with air. Guichard, Clausmann and Billon. *Bull. soc. chim.* **43**, 752(1928).—Alloys of Ag and Cu, when fused in the air, often show a change in wt. An alloy, 72.1% Ag, heated at 1000° for 2 hrs., was found to have become 74% Ag. The alloy, heated at 1300° to 1400°, had its Ag content reduced to 71.5%. There are two opposing influences, the one a disappearance of Cu due to oxidation at the lower temps., and the other the volatilization of Ag at higher temps. An alloy, 89.5% Ag, heated at 1100°, showed no change in compn., both Ag and Cu being removed at the same rate.

E. G. VandenBosche

The deoxidation of cast silver. Guichard, Clausmann and Billon. *Bull. soc. chim.* **43**, 752-3(1928).—The addn. of 0.1% Cu_3P_2 is very effective as a deoxidizer when fusing alloys of Ag and Cu. The qualities of the alloy are improved and a smaller no. of reheatings are necessary in the process of rolling than when the melt is simply protected with a layer of pulverized charcoal. E. G. VandenBosche

The swelling in hydrogen of silver and oxidized copper alloys. Guichard, Clausmann and Billon. *Bull. soc. chim.* **43**, 748-51(1928).—The swelling of Ag and Cu alloys contg. some oxide, when heated in a current of H_2, previously reported (*C. A.* **22**, 2542), is further discussed. Photographs are given of both etched and polished

metals. With alloys contg. a rather large amt of Ag reduction penetrates toward the center of the sample more readily and cracks appear on cooling. E. G. v. B.

Laboratory uses of Monel metal. L. F. Bates and R. C. Brown Univ. College, London. *Nature* **122,** 240(1928).—The phys. properties of the Cu-Ni alloy, monel metal, make it useful for a number of lab. expts. Its low magnetic crit. temp. (100–50°) makes it applicable to illustrate the loss of ferro-magnetism with rise in temp. It has also been used as tips to measure the surface tension of liquids by the drop wt. method, or that of Hg by Jaeger's jet method. In these it is superior to glass because of its resistance to corrosion. H. F. Johnstone

Heusler's alloys. The system manganese-aluminum-copper. Otto Heusler. Inst. phys. Chem. Göttingen. *Z. anorg. allgem. Chem.* **171,** 126–42(1928); cf. *C. A.* **21,** 1215.—H. made a thermal and microscopic study of Mn-Al-Cu alloys, rich in Cu, by fusing together binary alloys of Cu-Mn contg. 15 and 30% Mn, respectively, with varying amts. of Al The areas of separation of ternary α- and β-solid solns. were detd. The β- solid soln. undergoes a change in compn. by the formation of α-crystals and at temps. below 540° breaks up into a eutectoid mixture of α- and γ-solid solns This breakdown is exceedingly slow For the malleable Mn-Al-Cu bronze of compn. (14, 10, 76%) annealing for several weeks at 300° is required to decompose the β-crystals completely. Neither the α-crystals nor the eutectoid mixture of α- and γ-crystals is magnetic. Since cooling curves did not show when the β-crystals become ferromagnetic, H took differential heating curves of samples of the (14, 10, 76) alloy quenched from 700°, first unaged and then aged for different lengths of time at 40°, 80°, 184°, 230°, 300° and higher The thermal data agreed with the results previously obtained by Take (*C. A.* **5,** 1731) who examined the same alloy magnetometrically. There is a heat evolution at temps ranging from 100 to 290° due to the formation in the β-crystals of ferromagnetic molecules (presumably $Al(Mn,Cu)_3$) from the uncombined atoms as a result of the aging process since *quenched* specimens of β-solid solns. are non-magnetic. Heating for 1000 hrs at 300° destroys the β solid soln. completely and the differential heating curve then shows that the thermal effect of the magnetic transformation (below 300°) has completely disappeared H. S. van Klooster

Age-hardened manganese-copper alloys. Fr. Heusler. Dillenburg, Hessen Nassau. *Z anorg. allgem. Chem* **171,** 146–62(1928); cf preceding abstr. H. gives the mechanical properties of some Mn Al-Cu alloys (5, 9, 86 and 13, 9, 78%) and of Mn-Si Cu alloys (12, 3, 85%; 8, 2, 90 and 5, 2, 93%) in the sand-cast and in age-hardened condition. An explanation is given of the *ferromagnetism* induced in the Mn-Al-Cu alloy of compn (13, 9, 78%) when age hardened at 80° (cf. *C. A.* **21,** 3880). This change does not produce any visible differences in the microscopic appearance of the etched alloy. Aging at temps. above 80° results in the gradual decompn. of the ferromagnetic β-solid soln into the non-magnetic α- and γ-solid solns. This decompn. is easily demonstrated by the microscopic appearance of the alloy when aged for different lengths of time at 235°. In the appendix E. Donnges presents tables and graphs on the hardness and the elec. cond as a function of temp and duration of aging for hot-rolled bars of 2 Mn-Al-Cu alloys (13, 9, 78 and 5, 9 86%) and one Mn Si-Cu alloy (5, 2, 93%). H. S. van Klooster

Metal protection in galvanizing technic with special regard to the so-called intermediate layers before galvanizing. E. Krause. *Korrosion Metallschutz* **4,** 153–7 (1928).—A review of the present-day methods of electroplating for corrosion prevention with emphasis on the need for intermediate layers to obtain more adherent coatings. B. E. Roetheli

Metal-spraying process and the prevention of corrosion. R. Hoffer. *Chem. Fabr* **1928,** 316 8.—The process consists of the melting of a wire in an oxy-H flame and the atomization of the molten drops by a current of air. Plated surfaces not more than 0.02 mm. thick and of reasonable strength can be made in this way. It is essential that the droplets should be hot when they strike the surface to be plated, and that the latter should be roughened. All metals can be sprayed which m. below 1600° and are available as wire. The surfaces produced are, however, porous, and the process is only useful when they can be improved by chem. or mech. means. In the case of Fe covered with Zn, the porosity is no disadvantage, as the Zn acts as an elec. protector. Al coatings have found an extended use. The plated material is heated in absence of air, when alloying at the surface of contact takes place and the coating becomes non-porous. A partly alloyed Al coating, especially with an addnl. Zn coating, is a good protection against SO_2. A more completely alloyed Al coat is protective against oxidizing gases at temps. up to 1000°. B. C. A.

Acid resistance of pure chromium-nickel-iron alloys. W. Guertler and W.

Ackermann. Berlin-Charlottenburg. *Z. Metallkunde* **20**, 269-79(1928).—A study of the resistance of Cr-Ni-Fe alloys to acid attack with the object of testing Tammann's conclusion that the protection given to an alloy in the mixed crystal series by one of its constituents is greatly increased when the atoms of the protective element equal $^1/_8$ of all the atoms present (*Z. anorg. allgem. Chem.* **107**, 1). The alloys were prepd. from electrolytic Fe, pure Ni powder (Kahlbaum), and alumino-thermally prepd. Cr. After solidification the alloys were heated in a vacuum at 1200° for 4 hrs. Each sample was exposed to the action of 1% and 20% HNO_3, 1% H_2SO_4, 1% HCl, 1% HCl + H_2O_2, 5% AcOH, 5% KOH, 5% KOH + H_2O_2, the extent of the attack being measured by loss in wt. in g./sq. cm./hr. A more rapid method consisted in immersing a polished surface in the acid and observing the beginning of attack under the microscope, the time for etching to appear being taken as a measure of resistance to attack. Results are given in curves. In HNO_3, Fe-Ni alloys show a very strong reduction in attack at 12.5 and 25 atomic % Ni, or at $^1/_8$ and $^2/_8$ of the total no. of atoms in the mol. Cr-Fe alloys show complete passivity above 12.5 atomic %. In the ternary alloys Cr alone seems to produce a protective action, no attack occurring when more than $^1/_8$ of all the atoms are Cr. In H_2SO_4 considerable attack takes place upon the Fe-Ni alloys unless Ni is over 12.5 atomic %. Cr exerts no protective action in H_2SO_4 as in Fe-Cr alloys the attack actually increases at the $^1/_8$ and $^2/_8$ points. With the ternary alloys, protective action occurs when Cr + Ni atoms are at least $^2/_8$ of the total no. of atoms. If less than this amt. is present the alloy is more vigorously attacked than pure Fe. None of the alloys prepd. showed appreciable resistance to HCl, but in the HCl + H_2O_2 mixt. alloys contg. more than 11.74% Cr ($^1/_8$ mol.) become passive. Similar results are obtained in AcOH, the protective action being attributed to the formation of a $Cr(OH)_3$ film by hydrolysis. KOH and KOH + H_2O_2 gave no attack on any specimens. In general it is shown that in oxidizing agents or in such solns. where the formation of an oxide skin is possible, Cr is the protecting element, while in non-oxidizing solns. such as H_2SO_4 the Ni is the element which exerts the retarding influence. H. Stoertz

Corrosion phenomena. XIII. The solution of metals accompanied by hydrogen evolution—the catalytic influence of non-homogeneous metals and their relationship to the overvoltage series. A. Thiel and J. Eckell. *Korrosion Metallschutz* **4**, 121-33, 145-51(1928); cf *C. A.* **22**, 1715.—The soln of metals accompanied by H_2 evolution, the catalytic influence of non-homogeneous metals and its relationship to the H overvoltage series were studied (cf. *C. A.* **22**, 209). Expts were made on the soln of Al in HCl with results similar to those observed with Zn The previous explanation of the "difference effect" (*C. A.* **22**, 209) is claimed to be erroneous in stating that the theory of non-homogeneous metals is linked with the theory of diffusion of residual currents The fact that stirring causes no change in the "difference effect" refutes this explanation. B. E. Roetheli

Methods of corrosion testing with the aid of indicators. Heinrich Thiele. *Korrosion Metallschutz* **4**, 152-3(1928).—The initial progress of corrosion of metals can be followed by use of suitable indicators. Dyes which become colorless on reduction and $FeCl_3$-$K_3(Fe(CN)_6)$ soln. in agar are suitable for non-ferrous metals. Ferroxyl indicator is used for Fe. Since $K_3(Fe(CN)_6)$ is a strong oxidizing agent, only small quantities are used in the agar. The metal is immersed, removed after a short time, and exposed to H_2S or NH_3 vapors. In the case of Cu, the corroded portions appear black or blue, resp. B. E. Roetheli

Electrochemical polarization process for prevention of corrosion in locomotive boilers. L. O. Gunderson. Chicago and Alton R. R. Co. *Ind. Eng. Chem.* **20**, 866-9(1928).—Arsenic added to feed water as a sol. salt is caused to plate out on tubes, etc., by an e. m. f. imposed by headlight generator through the use of iron anodes, with resultant protection to cathodic parts. A discussion of thermally generated currents and their role in corrosion is given. Excellent results are reported from the practical application of this method in locomotive boilers. J. K. Roberts

Investigations regarding the action of various kinds of ethyl alcohols on sheet aluminum and Lautal. H. Röhrig. *Korrosion Metallschutz* **4**, 133-5(1928).—Sheet Al and Lautal were immersed for 120 days at 20° and 21 days at 78° in EtOH from various sources. Losses in wt., strength and ductility were measured. The 3 properties changed similarly. Abs. alc. and high-grade alc. were non-corrosive, while raw molasses spirits, spirits from sulfite liquor and raw spirits were increasingly corrosive in the order named. B. E. Roetheli

Electrolytic destruction of pipes. W. B. McCabe. *Commonwealth Eng.* **15**, 475-7(1928).—By comparing the elec. railway and telephone distribution in Mel-

bourne with that in Dublin, it is concluded that in Melbourne considerable destruction in pipe lines is taking place electrolytically. It is suggested that the laying of wood stave pipes is a possible remedy. J. K. ROBERTS

Corrosion in steam heating systems. F. N. SPELLER. *Domestic Eng.* (Chicago) **122**, 23–4, 61–2; *J. Am. Water Works Assoc.* **20**, 158.—Moisture, O, and CO_2 are the essential factors responsible. D. K. FRENCH

Corrosion phenomena on aluminum-bronze pipes, their causes and steps taken for their prevention. A. MERZ AND E. BRENNECKE. *Korrosion Metallschutz* **4**, 136–40 (1928).—Exposing cold-worked Al bronze to alkali chloride solns. in preheaters resulted in failure by pitting in 4 weeks. Microscopic examn. of the metals showed the attack to be centered at grain boundaries and slip bands. The attack was essentially eliminated by heat-treating long enough to permit recrystn. B. E. ROETHELI

The corrosion of iron and its anodic polarization. R. A. DENGG AND H. J. DONKER. *Korrosion Metallschutz* **3**, 241–6(1927).—Current density-e. m. f. curves were obtained for six com. irons of different compns immersed in a soln 0.1 *N* in KCl and 0.1 *N* in K_2CO_3 to det. the effects of compn. on the e. m. f. required to overcome the resistance of the protective film. The e. m. f. required decreases with increasing C content. In the light of the theory of protective film formation in alk. solns. the authors claim that the possibility of having corrosion occur on Fe depends upon the compn. of the electrolyte. Upon immersing an anode in a chloride-carbonate soln. the current at const. e. m. f. falls off with time. The current has 2 functions, strengthening the protective film and satg. inaccessible areas with O_2. A minimum potential is required to start corrosion. If the potential required is between those of O_2 and Fe, corrosion can proceed. If the potential required be higher than that for O_2 in the same soln., no corrosion can take place. Since the Fe assumes the potential imposed upon it by O_2, it is reasonable to suppose that the impurities take on a potential imposed by the O_2. Hence the most detrimental impurity is the one which assumes the highest potential In case of Fe the Fe itself is dangerous. The authors assert that when in contact, the nobler of 2 metals is not always protected when immersed. If the two be brought into contact in a soln. in which the nobler has a smaller penetration potential than the more base, then the former will go into soln. and the latter will behave as cathode. In this case the nobler protects the more base. Noble metals are protected only when the base metal can go into soln. Pitting is explained by weaknesses in the protective film due to irregularities in the structure of the metal underneath. As soon as the film is penetrated the metal goes into soln. decreasing the OH^- concn. surrounding the point of attack, thus accelerating the corrosion. Corrosion occurs at slag inclusions only because of probable differences in the structure of the metal at the slag boundaries. The fact that NaOH gives better protection than K_2CO_3 is not due to OH^- concn. since in solns. of both having the same p_H, the K_2CO_3 is far superior. The method used in this investigation is claimed to give good indication of corrosion conditions occurring in practice. B. E. ROETHELI

Protection of iron structures against corrosion in sea water. HAYSSEN. *Korrosion Metallschutz* **4**, 182(1928).—Materials contg. bitumens were applied to the gates of locks in the Kiel canal. The coatings are in themselves impervious to sea water but by the action of small shell fish, which eat through the coating and deposit a calcareous scale, the metal is exposed to the corrosive action of the H_2O. B. E. ROETHELI

Testing of pickling inhibitors. HEINZ BABLIK. *Korrosion Metallschutz* **2**, 179–81 (1928).—A discussion of the methods in use for testing inhibitors for pickling baths. The importance of detg. relative lengths of time necessary for pickling and the stability of the inhibitor subject to the action of nascent H and heat is emphasized. B. E. R.

Regarding corrosion phenomena. XIV. With reference to the protective effect in the corrosion of iron under steam boiler operating conditions. A. THIEL AND H. LUCKMANN. *Korrosion Metallschutz* **4**, 169–77(1928).—A description is given of a method of corrosion testing of Fe by weighing the H_2O formed from H_2 evolved on heating the metal for extended periods of time in solns. at 100°. Fe was also treated in *N* NaOH solns. contg. varying quantities of Na_2CO_3, NaCl, Na_2SO_4 or Na_3PO_4 in presence of O_2 at 200° in an autoclave. The wt. increase of the metal was measured after 2 hrs. The H_2 evolution data showed 0.01 *N* NaOH to be $^1/_3$ as corrosive as distd. H_2O and 0.05 *N* NaOH $^1/_4$ as corrosive. The presence of air did not appreciably affect the results. The wt. increment data showed the addns. of Na_2SO_4, NaCl and Na_2CO_3 to accelerate corrosion increasingly, while Na_3PO_4 reduced it about 80%. The corrosiveness of the added salt depends upon its concn. The conclusion regarding the known protective influence of Na_2SO_4 is that in solns. in which the concn. of Na_2SO_4 is great enough to form scale a protective film is pptd., and where

the soly. of Na_2SO_4 is not exceeded no protection can be expected. **XV. The results of the work on corrosion in Darmstadt and their relation to the investigations at Marburg.** A. Thiel. *Ibid* 177-8.—An article comparing the contemporary work of the two institutions on boiler water investigations B. E. Roetheli

Corrosion of condenser tubes—"impingement attack"—its causes and some methods of prevention. R. May and H. C. H. Carpenter. *J. Inst. Metals* (advance copy) No. **471,** 35 pp.(1928).—Introduction by C. reviews the work of the Corrosion Research Committee. This investigation deals with the effect of intermittent cavitation of entering water and of air bubbles on the deterioration of condenser tubes. The behavior of protective films was studied by measurement of "film potentials" (f. p.) The potential between test specimen cut from condenser tube exposed to jet and calomel electrode (cathode) was measured with no current flowing, the difference in p. d with the protective film intact and absent being the f. p. A comparison of installed tests with this method showed excellent agreement (f.-p. curves for 70:30 arsenical brass and a 2% Al brass are given). Admission of air in water and scratching had marked effects on the f p. Expts. on an installation of tubes showed that air bubbles alone could cause impingement attack The size of air bubbles is important, very small bubbles producing only slight attack. A jet tester used in the bubble work is described Methods of prevention of impingement attack in condensers are given, including elimination of rotary motion in water boxes, use of grids to reduce cavitation, use of resistant materials, etc.. 70:30 cupro-nickel and 2% Al brass are recommended for resistance to impingement attack. Small increase in CO_2 content of water may remove protective scale from tubes. Also in *Engineering* **126,** 309 12(1928). J. K. Roberts

Corrosion at discontinuities in metallic protective coatings. Ulick R. Evans Cambridge Univ. *J. Inst. Metals* (advance copy) No. **467,** 33 pp.(1928).—Sprayed coatings of Cu, Ni and Al on steel base metal and hot-dipped, electrodeposited, sprayed and sherardized Zn coatings on steel were exposed to various types of atmospheric and submerged corrosion tests. Cracking of the coatings was produced by bending and porosity of sprayed coatings by variations in amt. of metal sprayed on. The tests were by partial immersion in 0.5 *N* NaCl soln, partial immersion in tap water, intermittent spraying with 0.5 *N* NaCl soln, intermittent spraying with 0.01 *N* H_2SO_4, by exposure to air contg SO_2 and H_2O, and by exposure to air contg. HCl. It was concluded: that cracks in coatings produced by bending cause enhanced corrosion of anodic coatings or of base metal in cathodic coatings; that in immersed corrosion, rust is pptd. outside of coat while in atmospheric corrosion the rust ppts. underneath and pushes coating away from steel; that Zn protects exposed steel spots by sacrificial corrosion and hence thick coat is beneficial even though it cracks worse; that Zn builds up protective coating in atm corrosion but not in submerged corrosion; and that Al coatings are less attacked than Zn but give no protection at cracks in Cambridge water Also in *Engineering* **126,** 407 8(1928). J K Roberts

Ore flotation. Adolphe H Ney. U. S. 1,683,724, Sept 11 A mineral such as Cu ore in the form of an alk pulp is subjected to froth flotation in the presence of the products of reaction of an excess of S_2Cl_2 upon *o*-toluidine or other suitable aromatic amino compds having at least one *o* position to the amino group unsubstituted

Flotation apparatus. Ferd. P Egeberg. Norw 43,996, May 9, 1927.

Treating ores. Quincy Bent, Edwin Barnhart and Frederick W. Wood (to Bethlehem Steel Co.). U. S. 1,684,006, Sept. 11. Mayari Fe ore or other wet ores of plastic character are rendered suitable for a subsequent furnacing operation by feeding the ore into the cool end of an internally and longitudinally ribbed rotary kiln by which the ore mass may be divided into a plurality of integral masses disposed longitudinally of the kiln, the kiln is inclined and is rotated to carry the masses to a point where they become detached and fall during the rotation of the kiln, and the material is heated to effect partial drying in the kiln. An app. is described.

Treating ores and alloys by crystallization. H Skappel. Norw. 43,940, April

19, 1927. Ores, alloys or other metallurgical products are recrystd. in fused, sintered or heated condition under addn. of a substance which will form a part of the eutectic mixt. and which is easily attacked by chem. reagents. After being cooled the mass is treated with a chem. reagent until the said substance is dissolved or decomposed. The mass will then crumble to a powder consisting of different cryst. and amorphous components which can be sepd. in known mech. or chem. ways.

Treating manganese ore. J. C. WIARDA & Co. Brit. 284,098, March 1, 1927. The Mn content of a Mn-bearing ore is reduced to MnO by roasting the finely divided ore in the presence of a gaseous or solid reducing agent, and the ore is then leached with $(NH_4)_2SO_4$ soln. at a temp. of about 80° and liberated NH_3 is recovered. The $MnSO_4$ soln. formed is filtered and cooled and may be treated with the liberated NH_3 to form $Mn(OH)_2$ and regenerate $(NH_4)_2SO_4$. The $Mn(OH)_2$ may be dried and heated to form pure MnO. NH_4Cl also may be used instead of $(NH_4)_2SO_4$.

Reducing iron ores. J. W. HORNSEY and H. E. COLEY. Brit. 284,040, July 26, 1926. Fe ores or oxides are preheated in an inclined rotary chamber and then passed, without access of air, into a second inclined rotary chamber, from which the air is practically completely excluded, where the material is mixed with carbonaceous material contg. hydrocarbons (suitably coal, peat, or lignite) and this chamber is heated to such a temp. that the hydrocarbons are cracked and the products reduce the ore or oxide to practically pure Fe.

Gas reduction of slimy iron ore. AKTIESELSKAPET NORSK STAAL. Norw. 42,213, June 27, 1927. In the gas reduction of highly concd. slime in rotary channel furnaces the materials have a strong tendency to clog together and stick to the furnace lining. The reduction of low-percentage slime works excellently, but the sepn. of the resulting Fe from the gang has been found difficult. Highly concd. slime is therefore mixed with an indifferent refractory substance, for instance, sand. This mixt. works excellently in the furnace and the sepn. of the Fe after the reduction is easy. The addn. substance may circulate in the process.

Extracting metals as carbonyls. I. G. FARBENIND. A.-G. Brit 284,087, Feb. 4, 1927. The process described in Brit. 269,677 (*C. A.* **22,** 1446) for the production of Fe from Fe carbonyl is applied to the treatment of other carbonyls or their mixts., such as Co, Mo or Ni carbonyls or their mixts. with each other or with Fe carbonyl. The carbonyls are preferably introduced into the decompn. chamber in the form of a vapor or mist and solid carbonyls may be dissolved in liquid carbonyls

Casting metals. SAMUEL T. G. SMITH. U. S. 1,683,630, Sept. 11. Powd. $BaSO_4$ is used for facing walls of molds and cores used for casting metals, in order to obtain smooth castings.

Iron castings with a low carbon content. KARL EMMEL and HANS WALBERT (Walbert's interest assigned to Emmel). U. S. 1,683,714, Sept. 11 A cupola furnace using solid fuel is employed for melting a charge of which the "iron portion" consists of at least 50% of iron low in C such as wrought iron or steel and the remainder of iron rich in C such as pig iron of high C and Si content. there are also added admixtures such as are usually employed in the production of gray cast iron and a quantity of coke about 9-13% of the total charge; the charge is submitted to a blast pressure of 400-500 mm water gage pressure which is varied according as the total C content in the product is to be nearer 2% or 3%.

Regenerative open-hearth furnace construction. STEWART J CORT (to Bethlehem Steel Co.). U S. 1,683,656, Sept 11.

Reverberatory furnace for annealing tin plates, etc. W. G. BEESTON. Brit 284,025, Dec 31, 1926.

Aluminum-melting furnace. PAUL H. ROMPH. Can. 283,523, Sept 25, 1928.

Metal coating. FLOYD C. KELLEY (to Can General Elec. Co., Ltd.). Can. 283,034, Sept 4, 1928. A heat protecting face of alloy of Fe-Cr and Si is produced on iron by heating in H in contact with a mixt. of powdered Cr, Si and Al_2O_3 at a temp of 1000°.

Protective coatings for metals and other materials. A. A. VAN DER MEULEN Brit. 283,664, Oct. 28, 1926. A compn. for producing muffle coatings on iron or steel or for preserving wood or stone, etc., comprises phenol 1-2 and linseed oil 40 parts. Siccatives, pigments, etc., may be added.

Zinc coating. JOSEPH G. FITZGERALD and HENRY C. BAKER (to The Central Alloy Steel Corp.). Can. 283,401, Sept. 18, 1928. Fe sheets are coated with Zn by heating the Fe in a Pb bath from 850° to 950° F., coating the sheets in a superheated molten spelter bath, and then controlling the cooling of the hot coated sheets to produce a tight coat of the desired character and appearance. Cf. *C. A.* **22,** 3128.

Pig iron. EMIL EDWIN (to Aktieselskapet Norsk Staal Elektrisk-Gas-Reduktion). Can. 283,386, Sept. 18, 1928. Synthetic pig iron is made by reducing Fe ore at low temp. into spongy Fe, sepg. the latter from harmful constituents by dressing, adding relatively pure carbonaceous material to the spongy Fe, smelting the charge in an elec. furnace under acid conditions and at as low a temp. as possible and adding to the fused bath required quantities of Si, Mn and like elements to obtain the desired grade of pig iron.

Aluminum sulfide. HARALD SKAPPEL. Norw. 44,467, Oct. 10, 1927. An impure raw alloy of Al contg. Fe, Si and Ti is brought to reaction with a suitable amt. of heavy-metal sulfides resulting in the *reduction of heavy metals* for instance Zn and Fe and the formation of pure Al_2S_3 which is worked by known methods for the production of *pure Al*.

Converting zinc dust into liquid zinc. AKTIESELSKAPET MALMINDUSTRI. Norw. 44,762, Jan. 16, 1928. Mech. features of app.

Alloy. STANLEY M. NORWOOD (to The Electro Metallurgical Co. of Can., Ltd.). Can. 282,700, Aug. 21, 1928. An alloy contains Cr 20–30%, Ni 6–12%, Si 1–2.5%, Mn 1–2.5%, C less than 0.3%, with the rest Fe.

Bearing-metal alloys. FIRM OF J. NEURATH. Brit. 283,862, Jan. 17, 1927. The bearing-metal alloys described in Brit. 238,895 (*C. A.* **20,** 1976) are modified by the addn. of about 0.5–3.5% of Cd or In or both. An alloy may, *e. g.*, be formed of Pb 66.8, Sb 25, Sn 5, As 1.2 and Cd or In 2%.

Magnetic alloys. H. F. PORTER. Brit. 283,931, Jan 20, 1927. An alloy suitable for use in transformers, relays, armatures, vibrators and similar app. comprises Fe 35–55, Ni 35–55 and Cu 3–10%. The alloy may be formed by melting, in an elec. induction furnace, a charge formed of alternate sheets of Fe and Ni superposed on top of either a Cu-Mn, Cu-Mg or Cu-Mn-Mg alloy or Cu superposed on Mn or Mn and Mg.

Magnetic alloy. WILLOUGHBY S. SMITH and HENRY J. GARNETT. Can. 283,451, Sept. 25, 1928. An elec. conductor produced from an alloy contg. Fe 14 to 15, Cu 14 to 16%, a deoxidizing metal not greater than 0.5%, and the remainder Ni is heat-treated to a temp. in excess of the magnetic change point of the alloy and cooled so that the initial permeability of the alloy is of the order of 6000. Cf. *C. A.* **22,** 939, 2917.

Aluminum alloys. T. GOLDSCHMIDT A.-G. Brit. 283,927, Jan. 20, 1927. Al alloys are formed contg. Mg silicide 1.3–1.7, Cu 1–1.4 and Ti 0.3–0.7%, with or without Mn 0.5–1.1%, and are improved after working, by heating at 520–550°, quickly cooling and aging at 110–160° for 6–24 hrs.

Aluminum alloys. J. STONE & CO., LTD. AND H. J. MAYBREY. Brit. 283,760, Feb. 26, 1927. In treating Al alloys, especially those contg. a substantial proportion (suitably 11%) of Si, B or its oxide or other B compd. such as borax is brought into exothermic reaction and in such state is used for treating the alloy; *e. g.*, the alloy may be melted and added to a pot contg. a reacting mixt. of Al, borax and $KClO_3$.

Aluminum alloys. P. BERTHELEMY and V. H. DE MONTBY. Brit. 283,926, Jan. 20, 1927. In modifications of alloy production as described in Brit. 252,028 (*C. A.* **21,** 1442): (*a*) the proportion of substances foreign to the Al may be held within definite and very narrow limits; (*b*) a rich alloy may be produced from a material contg. Cu such as cupro-Mn, cuproferro-Si or curpro-W; (*c*) the rich alloy may be incorporated in a mass of "French Al" of 99–99.5% purity; and (*d*) an alloy of Al, Mg and Cd may be finally added.

Alloys containing copper, nickel and zinc. R. K. HEZLET and R. GENDERS. Brit. 283,994, Oct. 16, 1926. Cu-Ni-Zn alloys contain also up to 2.5% of Al (the Ni and Al together being more than 15%). An alloy may, *e. g.*, be formed approx. of Cu 50, Zn 30, Ni 20 and Al 0.2–0.3%. Mech features of casting the alloys are described.

Alloy containing nickel, copper and tin. SEWELL E. WINSLOW (to Consolidated Ashcroft Hancock Co.). U. S. 1,683,749, Sept. 11. See Can. 271,976 (*C. A.* **21,** 3596).

Nickel alloys. RUSSELL FRANKS and BURNHAM E. FIELD (to Haynes Stellite Co.). U. S. 1,684,131, Sept. 11. Alloys which are suitable for "high speed" tools are formed of Ni together with Al 3–5, Si 3.5–6, W 5–12, Ti 6–12, and B in effective quantity up to 1%. Cf. *C. A.* **22,** 3128.

Lead alloy. HIROSHI YOSHIKAWA. Can. 283,382, Sept. 18, 1928. A Pb alloy contains Bi less than 10% and Cu less than 10%. Cf. *C. A.* **22,** 3624.

Treating lead alloys. STANDARD ELECTRIC A. S. Norw. 44,471, Oct. 10, 1927. The hardness and the tensile strength are very much increased in an alloy contg. about 97.5% Pb and 2.5% Sb by heating to 240° for 72 hrs., cooling in water and storing at

room temp. for 72 hrs. for ripening. A similar treatment is adaptable also to Pb-Sn and other Pb alloys.

Heat treatment of steel rails. NARAINA D. CHOPRA and FREDERICK J. BULLEN. Can. 282,943, Sept. 4, 1928. Steel rails are heated from a temp. below the lowest change point to a temp. above the highest change point of the steel, then cooled gradually to a temp. just below the lowest change point, and finally cooled rapidly. The heating and gradual cooling are effected in presence of a mixt. of CaO and ash carrying a small proportion of free C and steel turnings. The quantity is equiv. to 10% to 50% by wt. of the combined quantities of CaO and ash and the C content of the ash is such that the quantity of free C present is equiv. to 4 to 20% by wt. of said combined quantities. Cf. *C. A.* **22,** 1568.

Solder. H. MOCK. Brit. 284,001, Oct. 18, 1926. An easily disruptible solder suitable for sealing cans of foodstuffs comprises Pb 60, Sn 20 and Bi 20%.

Electrodes for arc welding. E. W. SCHWARTZ and F. R. KAIMER (to British Thomson-Houston Co., Ltd.). Brit. 283,582, Jan. 15, 1927. Electrodes are made with a relatively thin cond. coating comprising red oxide of Fe, lime or $CaCO_3$ or both, and Na silicate. The coating may be applied by boiling reels of electrode wire for 5-8 hrs. in an aq. mixt. of the coating substances.

Welding electrode. NORMAN B. PILLING and JOHN G. SCHOENER (to The International Nickel Co Inc.). Can. 283,068, Sept. 4, 1928. A welding electrode comprises a malleable Ni or Ni alloy contg. Ni, C, Mn and Mg having associated therewith a coating comprising a Ti alloy and a Ca alloy having the Ti and Ca in the proportions of 19 and 6%, resp., by wt. of the coating, the Ti alloy and the Ca alloy being maintained in coöperative relation to each other and to the electrode by a shellac binder. Cf. *C. A.* **22,** 3625.

Electrodes for arc welding. P. P. ALEXANDER (to British Thomson-Houston Co., Ltd.). Brit. 283,483, Jan. 10, 1927. Metal electrodes of low C content are used in the presence of a hydrocarbon that will dissoc. in the arc and thus provide a protective atm. of H and liberate free C, which will impart characteristics to the weld similar to those of the "parent metal." Propane or natural gas may be used for this purpose and CO_2 or N may be added to vary suitably the compn. of the gaseous mixt. An app. is described. Cf. following abstract.

Electric welding. PETER P. ALEXANDER (to Can. General Elec. Co., Ltd.). Can. 283,039, Sept. 4, 1928. Welds are carburized by producing about the elec. arc a gaseous mixt. of a hydrocarbon and N, the hydrocarbon being dissociable in the arc to produce H and free C, the proportions of the H and N being such that a sufficient amt. of H is present to neutralize the effect of the O of the atm. in welding in the open air. Cf. preceding abstract.

Electric welding. PHILIP K. DEVERS (to Can. General Elec. Co., Ltd.). Can. 283,040, Sept. 4, 1928. Ductile welds are produced by the elec. arc process, by enveloping the arc and molten portions of the work with an active reducing gaseous medium comprising H dild. with N and A.

Electric welding. PETER P. ALEXANDER (to Can. General Elec. Co., Ltd.). Can. 283,035, Sept. 4, 1928. Ductile welds are produced by maintaining an elec. arc between a pool of molten metal on the work to be welded and a welding pencil of metal to be deposited on the work and applying a stream of a gaseous mixt. comprising sufficient H to surround the arc and in contact with the molten metal to exclude atm. air and exert a strong reducing action on the molten metal.

Autogenous welding. JOSEPH W. MEADOWCROFT (to Edward G. Budd Mfg. Co.). Can. 283,239, Sept. 11, 1928. A cleaned filler body of Al is coated with a flux consisting of 3.00% K_2CO_3, 3.70% KCl, 6.90% LiCl, 7.20% K_2SO_4, 20.00% $Na_2B_4O_7$, 21.00% $B(OH)_3$, 38.20% Na_2CO_3 mixed with H_2O and brought to the consistency of light cream.

10—ORGANIC CHEMISTRY

CHAS. A. ROUILLER AND CLARENCE J. WEST

The centenary of Wöhler's synthesis of urea. A. WOHL. *Z. angew. Chem.* **41,** 897-902(1928). E. H.

The action of columbium and tantalum pentachlorides on organic compounds. II. H. FUNK AND K. NIEDERLÄNDER. *Ber.* **61B,** 1385-8(1928); cf. *C. A.* **22,** 1577.—The action of these chlorides on the aromatic hydrocarbons benzene, naphthalene, tetrahydronaphthalene and anthracene gives HCl and intensely colored compds., not cryst.

Compds. prepd. were: $TaCl_4.C_6H_5$, $C_6H_6.3CbCl_5$, $TaCl_5.C_{10}H_8$, $TaCl_4.C_{10}H_7$, $TaCl_3$-$(C_{10}H_7)_2$, $CbCl_4.C_{10}H_7$, $CbCl_3(C_{10}H_7)_2$, $TaCl_4C_{10}H_{11}$, $TaCl_3(C_{10}H_{11})_2$, $TaCl_5.C_{14}H_{10}$, $TaCl_4.C_{14}H_9$, $TaCl_3(C_{14}H_9)_2$, $CbCl_4C_{14}H_9$. The similarity of some of these compds. to those previously prepd. (*C. A.* **22**, 1577) from O-contg. org. compds. leads F. and N. to believe that metal-C bonds exist there also. They present the view that these Cl-contg. compds. hydrolyze with aq. NH_3 and that the weakly acidic compds. thus formed give NH_4 salts G. R. YOHE

Evolution of acetylene from calcium carbide by the action of water, hydrogen sulfide and hydrogen chloride, in the liquid and gaseous conditions. E. BIESALSKI AND H. VAN ECK. *Z. angew. Chem.* **41**, 278-82(1928).—The extent of the gas evolution depends on the extent to which the reacting vapor is absorbed by the carbide, and on the degree to which the solid products formed protect the remaining carbide from further attack. Dry steam decomps. 20% of the carbide present in 2 hrs. at 130°; at 450° there is no attack. This is due to the formation of C by dissocn. of C_2N_2, the C protecting the carbide from further attack. H_2S and HCl both react exceedingly slowly in the gaseous state; even the liquefied gases react very slowly, since in both cases the solid products protect the carbide from further attack. B. C. A.

Behavior of calcium carbide toward free halogens and sulfur. E. BIESALSKI AND H. VAN ECK. *Z angew. Chem.* **41**, 720-3(1928); cf. preceding abstr.—Br and CaC_2 react slowly at the ordinary temp., about 80-90% of C_2Br_6 being formed after 3-5 months. At higher temps. little or no C_2Br_6 is formed, the carbide being decompd. with production of free C. Low temp. favors the production of C_2Cl_6 from CaC_2 and Cl, although the yield is small (3-5%). A certain amt. of C is produced, but the carbide is attacked very slowly, 80-90% remaining after 6 months Very little reaction occurs between I and CaC_2 at the ordinary temp , but 35-37% of $CI_2:CI_4$, together with considerable amts. of free C, is obtained after heating at 100-160° in sealed tubes for some hrs. A 20% yield of CS_2 and much C are obtained when CaC_2 and S are heated at 270°. Traces only of CS_2 are formed at 500° The 1st reaction, which is probably preceded by adsorption, is the formation of Ca halide or sulfide and C The latter can either polymerize or react with the agent to form halogen compds. or CS_2. The yield of halogen compd or CS_2 is detd. by the rates of the 3 reactions concerned. If the polymerized C accumulates the carbide becomes coated with a layer of C and the 1st reaction is prevented. The formation of a layer of Ca halide may also prevent further attack on the carbide. This latter effect is not of considerable magnitude with Br and I, since these readily form complex compds. with the corresponding halides. B C. A.

Methanol from hydrogen and carbon monoxide. RALPH L. BROWN AND A. E. GALLOWAY. Bur. of Mines. *Ind. Eng. Chem.* **20**, 960-6(1928) The exptl. production of MeOH from H and CO has been studied, with ZnO, basic Zn chromate and normal Zn chromate as catalysts The last 2 are more active than ZnO, and under high temps and pressures the normal chromate is the most active With the theoretical mixt. of CO and H at 400° and 180 atms., a 20% conversion of CO to MeOH has been obtained T S. CARSWELL

Citronellol and rhodinol. II. V. GRIGNARD AND J. DOEUVRE. *Compt. rend.* **187**, 330-4(1928); cf. *C. A.* **22**, 3879.—The essence from Bourbon geraniums or roses gives on vacuum distn. a so-called geraniol-rhodinol fraction (I), b_{18} 116-22°. On treatment with BzCl at 150° the geraniol (II) is destroyed, and the remaining product, which is a benzoic ester, is sapond to give a so-called rhodinol, b_{18} 118-9.5°, d^4_{15} 0.860, n^{15}_D 1.4574, $[\alpha]^{17}_D$ 1° 52'· allophanate m , 105-6°. Similar treatment of I with $C_6H_4(CO)_2O$ gives another so-called rhodinol, b_{17} 117-8.5°, d^4_{15} 0.864, n^{15}_D 1.4601. These so-called rhodinols are simply citronellol in which the treatment used to destroy II has caused isomerization. In *d*-citronellol ozonization shows 24% α form; treating it with BzCl converts it to 39% α-form Thus the rhodinol of Barbier and Bouveault is believed to be only a mixt. of α- and β-citronellol. D. H. POWERS

The allyl series. VENANCIO DEULOFEU. *Anales asoc. quim. Argentina* **15**, 418-22(1927).—Allyl acetate was prepd. first by Zinin (*Ann.* **96**, 361(1855)) from allyl iodide and AgOAc. No other method appears in the literature.
for investigation of its

... washed with dil. Na_2CO_3, then with concd. $CaCl_2$ and finally dried over $CaCl_2$ (yield 73%). It b. 103-5°. *β,γ-Dibromopropyl formate*, $HCO_2CH_2CHBrCH_2Br$, not hitherto prepd., was obtained from Br in CS_2 and allyl formate. These esters of $BrCH_2CHBrCH_2OH$ are interesting as a basis of prepn. of

unsym. glycerol esters unless transposition occurs. Thirteen g. of allyl formate in 65 cc. of CS_2 was treated with 40% Br in CS_2 with cooling until the color persisted for 8 to 12 min., forming the $HCO_2CH_2CHBrCH_2Br$. A few drops of allyl formate was added to discharge the color, the CS_2 evapd. on a water bath, and the residue distd. at 221–3° as an oily liquid, heavier than H_2O and of characteristic, irritating odor. The acetate, prepd by Aschan (*Ber.* **23,** 1827(1890)) from Ac_2O and the alc., and by Bancroft (*C. A.* **13,** 1856) from Br and allyl acetate, was made by treating 20 g. of allyl acetate in CS_2 with Br as above, distg. off the CS_2 on a water bath and continuing the distn. at ordinary pressure at 226.5–9°, giving a heavy liquid of irritating odor. For analysis of these compds. the Stepanov method (*C. A.* **1,** 397) with slight modifications was used. E. M. Symmes

Use of magnesium alcoholates in the preparation of ethers. V. Cerchez. *Bull. soc. chim* **43,** 762–7(1928).—*Mg amalgam* is prepd. by heating 24 g. of Mg with 364 g. of Hg under anhyd conditions. After cooling, 3 mols. of ROH is added; after several hrs. there are formed white crystals of ROMg. *Mg alkoxides* of *Pr* (I), *Bu* (II), *iso-Am* (III), *octyl* (IV), *cyclohexyl* (V) and *benzyl* (VI) *alcs.* have been thus prepd. Ethers are prepd. from these by heating in a salt-water bath until the excess alc. boils and slowly adding 2 mols. of Me_2SO_4. Heating is continued for 1–2 hrs., then the product is cooled, poured into dil. H_2SO_4, steam-distd., sepd. and fractionated, the final fractionation being carried out over Na. Yield, 70–80%. *Me ethers* are reported of II, b. 70°; III, b. 90–1°; IV, b. 158° and V, b. 133–5°. The ether of IV must be heated in an oil bath to 120–30° during its prepn.; octene is also formed, decreasing the yield greatly and requiring removal by washing the product with 1% $KMnO_4$. *Et ethers* of I, b. 63.6°, and II, b. 91°, were prepd. by using Et_2SO_4 at 120–30°. Yield, 60%. No ethers of VI could be prepd. A. S. Carter

Formaldehyde. Joseph Coulouma. *Rev. gén. mat. plastiques* **4,** 3–11, 73–85, 152–4, 263–72, 329–35(1928).—A review of its occurrence, function in nature, industrial uses (particularly in the synthetic resins industry), manuf., reactions and detn., with bibliography of 81 references. A. Papineau-Couture

Esters of α-linolenic acid hexabromide (isobutyl, amyl, propyl and isopropyl) from Philippine lumbang oil. Maria Luisa A. Vincente and Augustus P. West. *Philippine J. Sci.* **36,** 73–7(1928).—α-Linolenic hexabromide (I), m. 179.5–80.5°, was prepd. by the bromination of the fatty acids obtained by the sapon. of lumbang oil. With the corresponding alcs. I gives the following esters: 56% iso-Bu (II), m. 136–8°; 46% Am (III), m. 133–5°; 76% Pr (IV), m. 144–6°; 66% iso-Pr (V), m. 141–3°. These esters are all sol. in hot $C_6H_4Me_2$, PhMe, $PhCO_2Et$, AcOEt, Me_2CO, $PhCO_2Me$, C_6H_6, $CHCl_3$, CS_2, CCl_4, EtOH and iso-PrOH. II and III are insol. in hot MeOH and petr. ether. IV is sol. in hot MeOH, PrOH, and AmOH and slightly sol. in petr. ether. V is sol. in hot MeOH, PrOH, AmOH and petr. ether. J. S. Reichert

Chlorination of acetic acid. O. Yu. Magidson, I. G. Zilberg and N. A. Preobrazhenskii. *J. Chem. Ind.* (Moscow) **5,** 528–9(1928).—For the purpose of finding the most favorable conditions of chlorinating AcOH to $ClCH_2CO_2H$ the authors experimented with various catalyzers, using glacial AcOH contg. a slight quantity of Ac_2O. The *app.* consisted of a thick-walled flask provided with a reflux condenser and with a Cl tube reaching to the bottom of the flask; the condenser was connected with 2 wash flasks contg. water by means of tubes reaching just above the surface of the water. The operating temp. was that of a steam bath; the accelerating effect of artificial light was not used. At first the effect of *Brückner's compounded catalyzer* (cf. Brückner, *C. A.* **21,** 3345; **22,** 3819) consisting of P, PCl_5 and I was tried out. None of the 3 expts. made with this catalyzer gave satisfactory results. While B. claimed a complete chlorination in 2–3 hrs., the authors found that 20–23 hrs. of chlorination were required to obtain 50–60% of crystd. CH_2ClCO_2H and that the latter was contaminated with I, from which it could hardly be freed after repeated fractionations. The next 3 expts. were made with a catalyzer of *activated C* in the ratio of 30 g. per 687–700 g. AcOH. The yields after 23–37 hrs. of chlorination were 30.4–51% of the theoretical and the CH_2ClCO_2H obtained was characterized by its high degree of purity. Two expts. made on *contact chlorination* of AcOH by passing vapors mixed with Cl through a layer of activated C placed in a tube immersed in an oil bath at 190–200° were unsuccessful: the CH_2ClCO_2H formation was slight and a considerable quantity of AcOH was decompd. into $CHCl_3$, CCl_4, HCl and CO_2. The catalyzing action of *Sb powder* was also tried, by using 10 parts per 500 parts of AcOH; it was found that, whereas Sb greatly facilitates the chlorination of aromatic compds. by introducing Cl into the ring, it has no effect in the chlorination of AcOH. The best results were obtained by the use of *S as catalyzer*. S should be taken in large quantities (about 1–2% of the

AcOH) and should be subjected to a preliminary treatment with Cl for activation. At first S was placed in the flask and heated over a flame till it melted, then Cl was passed into the melted S till most of it was transformed into S_2Cl_2. After cooling, the flask was placed on a water bath, AcOH was added and Cl was passed in. With 600 g. AcOH and 12 g. S the yield was 58% of the theoretical after 15 hrs. of chlorination; with 661 g. AcOH and 12 g. S the yield of CH_2ClCO_2H was 83% after 17 hrs. The products obtained by this operating method had a faint odor of S compds. and were not as pure as those obtained with activated C as catalyzer. In these experiments about 10% of the AcOH was carried away by the current of HCl. Desiring to prevent this loss, the authors contrived a *combined app.* consisting of 2 flasks with 2 condensers, the latter being so connected that, whereas Cl entered the 1st flask, a mixt. of HCl and Cl entered the 2nd flask; the AcOH carried away from the 1st flask was largely retained in the 2nd. After 9 hrs. of chlorination in this improved app. an average CH_2ClCO_2H yield of 47% of the theoretical was obtained in the 2 flasks; thus, while the loss of AcOH was lowered, the speed of chlorination was doubled. The product obtained in the 1st flask was pure and crystd. BERNARD NELSON

A new method of inversion of geometrical isomers by an exothermic reaction: conversion of maleic into fumaric acid. P. NEOGI, SUKUMAR NEOGI AND MANAS P. CHATTERJI. Presidency College, Calcutta. *J. Indian Chem. Soc.* **5**, 279–83(1928).—Work is carried out to det. whether exothermic reactions bring about geometric inversion as postulated by Skraup (*Monatsh.* **12**, 107(1891)). Maleic acid (I) in H_2O was unaffected by passing a stream of SO_2 (II) through the soln. for 0.5 hr. I with MnO_2 (III) similarly showed no change. To I (1.5 g.) in 5 cc. of H_2O finely divided III (2 g.) was added. II was bubbled through the soln. for 5 min. The temp. rose from 27° to 60°. Fumaric acid (IV) sepd. at once in 50% yield and was recrystd. from alc. Keeping the temp. of the suspension at 10° during the addn. of II gave only 10% IV; at 90° a 52% yield was again obtained. When I is dissolved in alc. or Et_2O, III added, and II bubbled in, since II and III do not interact in these solvents, no IV was formed. With dil. alc., IV was formed. When III was replaced by PbO_2 or BaO_2 there was no interaction with II and no IV was formed. I in H_2O at 60° gives no IV. I in H_2O with the reaction products of II and III at 10° and at 60° forms no IV when more II is bubbled in. Inversion of I to IV apparently only occurs when II and III are allowed to interact in its presence. D. H. POWERS

Determination of the spatial configuration of two *cis-trans*-ethylenic isomers. BOURGUEL AND RAMBAUD. *Compt. rend.* **187**, 383–4(1928).—Zal'kind (*C. A.* **8**, 1419) by partial reduction of tetramethylbutinediol (I) with colloidal Pd obtained 2 tetramethylbutenediols, the α isomer (II), m. 76–7°, and the β-isomer (III), m. 69–70°. On dehydration both gave the same γ-oxide, but dehydration was more rapid in the case of II. S. therefore concluded (*C. A.* **17**, 1209) that II was the *cis-* and III the *trans*-form. Bourguel (*C. A.* **19**, 2651) by reduction of I with colloidal Pd obtained only III. B. and R. have made a quant. study of the internal dehydration of II and III, and have arrived at the following conclusions: III is the *cis*-isomer, not *trans*, as stated by S.; II is not a definite compd., but a solid soln. of about 83% of the *cis*-form and 17% of a *trans*-glycol, m. 101°, which B. and R. have isolated and have called γ-glycol. LOUISE KELLEY

The system of simple sugars and α-substituted fatty acids. KARL FREUDENBERG. *Naturwissenschaften* **16**, 581–7(1928).—A review of the configurational relationships of hexoses and their decompn. products. B. J. C. VAN DER HOEVEN

Preparation of glucosides of the α-series: crystallized α-methyl fructoside. HANS H. SCHLUBACH AND GUSTAV A. SCHRÖTER. Univ. Hamburg. *Ber.* **61B**, 1216–22 (1928).—The method of König and Knorr cannot be satisfactorily used for the prepn. of α-glucosides from β'-acetochloroglucose (I) because the I in many solvents, and especially in alcs., rearranges into the α'-compd. considerably more rapidly than it is converted to the glucoside. It seemed indispensable, therefore, to effect the replacement of the halogen by the alkoxy group so rapidly that the rearrangement by the alc. could not occur. K. and K. had found that when they treated their α'-acetobromoglucose with $AgNO_3$ in MeOH AgBr was pptd. immediately and quant. and tetraacetyl-β-methylglucoside was formed instead of the expected acetonitroglucose. For their present work, S. and S. chose Brauns' more readily accessible β-acetochlorofructose (II) instead of I. B. had already applied the K. and K. method to II but obtained only a sirup with a rotation of —4.1°. Repetition of his work gave a sirup with a rotation of 6.8° or, after sapon., of 6.6°. As II is hydrolyzed by H_2O with extraordinary ease to tetraacetylfructose (III), S. and S. tried the effect of binding the H_2O liberated in the K. and K. reaction; with anhyd. Na_2SO_4 and $CuSO_4$ they obtained products with rotations of 16.7° and 22.3°, resp., but they were still sirupy. They next tried $AgNO_3$

in MeOH on the II in Et_2O, neutralizing the liberated HNO_3 with Ag_2CO_3, and for the 1st time were able to obtain crystals of *tetraacetyl-α-methylfructoside* (IV), along with III. As the neutralization of the HNO_3 with Ag_2CO_3 proceeds rather slowly, however, C_5H_5N was substituted for the Ag_2CO_3; this has the further advantage that in neutralizing the HNO_3 it forms no H_2O which might lead to the production of III. To extend the applicability of the method to cases in which the $AgNO_3$ is not sol. in the alc. components, MeCN was tried as the solvent and found to be equally satisfactory. No simultaneous formation of the β-isomer of IV was ever observed. IV, m. 112°, $[\alpha]_D^{20}$ 45.0° ($CHCl_3$, *c* 1.3104); yield, 6.2 g. from 46 g. II. Its sapon. to *α-Me fructoside* (V) is difficult. With $Ba(OH)_2$ the V crystd. after 6 months, with NH_3 in MeOH only after seeding. Unlike the β-compd. it can be purified by crystn. only with difficulty. The higher alcs. (iso-Am, iso-Bu) are the best solvents for this purpose. Because of the long time required for the crystn. the purification has not been carried to completion and the consts., m. 96–7°, $[\alpha]_D^{20}$ 44° (H_2O, *c* 0.9116), are to be considered only as provisional. That the V belongs to the stable fructose series was shown by methylation with alk. Me_2SO_4 to the pentamethylfructose and hydrolysis of this with HCl to 1,3,4,5-tetramethylfructose. The rotation (in CCl_4) of the II changed, on standing 16 hrs. over $CaCl_2$ and KOH at about 8° and 15 mm., from —176.9° to —148°; in various solvents $[\alpha]_D$ after 0, 12 and 37 hrs., resp., was: CCl_4 —176.9°, —176.9°, —176.9°; MeCN —132.9°, —132.9°, . . . ; $CHCl_3$ (D. A. B. VI) —159.1°, —156.6°, —126.7°; MeOH —36.3°, —43°, —37°. C. A. R.

Sulfur sugars and their derivatives. XII. Xanthogenglucose and its cleavage to glucothiose (1-thioglucose). WILHELM SCHNEIDER, RUDOLF GILLE AND KURT EISFELD. Univ. Jena. *Ber.* **61B**, 1244–59(1928); cf. *C. A.* **21**, 1634.—It is suggested that 1-thioglucose and other S sugars with labile, "thiocarbonylic" S be designated as thioses (glucothiose, galactothiose, etc.) to distinguish them from "thioglycoses" in which an alc. sugar HO group is replaced by a SH group with the usual mercaptan properties. The S-contg. glycosides are to be correspondingly classified as "thiosides" with a true thioglycosidic union of the aglycone (*e. g.*, Me glucothioside, hitherto known as Me thioglucoside), and true "thioglycosides," *i. e.*, S-contg. glycosides in which the aglycone is bound through an ordinary *O*-glycosidic union with the sugar (*e. g.*, 3-thiomethylglucoside). S. also retains, in spite of all philological objections, the designations "glucose, glucosides" for dextrose and its derivs. and "glycoses, glycosides" for monosaccharides in general. In connection with attempts to synthesize sinigrin, the prepn. of glucothiose (I) has been taken up again in agreement with Bergmann who observed that acetobromoglucose smoothly reacts with $EtOCS_2K$ to form an acetoxanthogenglucose (II), which yields I on hydrolysis. The II, was obtained in 2 dimorphic forms, the higher melting being the stable form at room temp. Sapon. with alk. reagents, especially NH_3 in MeOH, does not give the free xanthogenglucose (III) but yields I directly, but the Ac groups can be split off, without affecting the xanthogen group, with acids; HCl in MeOH proved best for this purpose but H_2SO_4 in MeOH and even aq. HCl sometimes effected the desired result. The III, $HOCH_2\underline{CH.CH(OH).CH(OH).CH(OH).C}HSCSOEt$, seps. from concd. aq. soln. or, better, from Et_2O satd. with H_2O, with 2 mols. H_2O of crystn. In anhyd. form, it cannot be obtained entirely pure. Towards acids, even in H_2O, it is strikingly stable, and even on boiling with dil. H_2SO_4 in the presence of $CuSO_4$ it only slowly decomps. with formation of $EtOCS_2Cu$. The I obtained from II with NH_3 in MeOH has the same properties as described in earlier papers. In spite of many variations in the conditions of sapon. and isolation, the products obtained never had as high a S content as Wrede's compd. (*C. A.* **16**, 3637), the max. being only around 15%. The C and H values were correspondingly higher, excluding the suggestion, made previously, that the low S content was due to the presence of 1 mol. H_2O. Acetylation of the isolated I or of the sirupy crude sapon. residue always gave amorphous products from which no cryst. pentaacetylglucothiose (IV) could be obtained, indicating that they were mixts. of different Ac derivs. In fact, from such a mixt. was isolated the acetate of diglucosyl disulfide (V). In the hydrolysis with NH_3 in the air, even when carried out rapidly, V seems always to accompany the I in varying but generally not inconsiderable quantities. Surprisingly enough, if air is rigorously excluded during the hydrolysis of the II, the products are still poorer in S (13–4%). In the hydrolysis, as followed optically, the SCSOEt residue is split off with materially greater velocity than the Ac groups. The intermediate tetraacetylglucothiose (VI) could not be isolated as such, but by allowing the hydrolysis at 0° to run only 1 hr., evapg. *in vacuo* and reacetylating

the sirupy residue, IV was obtained almost quant. Attempts to prep. I from the purified IV exactly according to Wrede's method gave no better products than did the hydrolysis of II with NH_3 in MeOH, but with Zemplén's method cryst. alkali salts of I can be obtained with the greatest ease. The *Na salt*, $C_6H_{11}O_5SNa.2H_2O$ (VII), is stable when dried in the air and also in H_2O, even on heating, if air is excluded. Its Na content can be detd. by titration with Me orange but not with phenolphthalein. In H_2O in the air it oxidizes in the course of a few days to V. H_2O_2 effects the oxidation instantaneously; if the destructive action of the excess of H_2O_2 on the V is hindered by faintly acidifying there is obtained a soln. whose max. *l*-rotation approaches within a few % the value found by Wrede for his amorphous V. The Ag compd., obtained from VII with NH_3-AgOAc, resembled in all respects the amorphous prepns. previously obtained from the free I except that after isolation and drying it completely lost its original soly. in H_2O. In freshly prepd. aq. soln. VII is *d*-rotatory ($[\alpha]^{20}_D$ 15.5°) and the rotation does not change if air is excluded. With Ac_2O in C_5H_5N is obtained only β-IV, with EtI only β-Et glucothioside (VIII). The free I shows mutarotation, the rotation, $[\alpha]^{20}_D$ 16.5°, of the soln. slowly increasing to a max. in about 10 days, but even if air is excluded there is distinct decompn. during this long period. In the presence of a slight excess of mineral acid (say, 0.002 *N*), the max. rotation is attained in 3 days and there is no appreciable decompn. (only a minimal cleavage of H_2S could be detected qual.), so that the end value so obtained, $[\alpha]^{20}_D$ 58.4°, may be considered as corresponding to the mutarotation equil. of the α- and β-forms. The rotation of the glucothiose ion, calcd. from that of the Na salt, is 20.1°, the value 16.5° given above for I being the rotation of the I as it exists in soln., chiefly in undissociated form. Higher concns. of free acid affect neither the velocity of the mutarotation nor its final value, and as the Na salt shows no mutarotation it may be concluded that only the undissociated I is capable of rearrangement. When a soln. of I which had attained the mutarotation equil. was evapd. and the residue was acetylated in C_5H_5N, it was found possible to sep. the product by crystn. into 2 fractions, (IX) and (X), the less sol. one (IX) being apparently the known β-IV, while X is a new compd., very probably α-IV. *Tetraacetyl-d-glucose Et xanthogenate* (II) (yield, almost 90%), prisms, m. 88-9°, $[\alpha]^{20}_D$ 30.8° in $(CHCl_2)_2$ (*c* 3.197). At times needles were obtained along with the prisms and occasionally the prisms on recrystn. changed into needles and their m. p. fell. The m. p. of the needles varied from 74° to 89°. The 2 forms do not appreciably differ from each other in compn. and properties. The needles, in contact with their own satd. soln. in alc., change in the course of 1-2 weeks into the prisms, while the latter remain unchanged under the same conditions. *d-Glucose Et xanthogenate* (III), sinters about 87°, m. 92-8°, $[\alpha]^{20}_D$ -50.5° (H_2O, *c* 1.396); the dihydrate, m. 63-5° and slowly weathers in a desiccator, even under atm. pressure. β-IV, m. 119-21°, $[\alpha]^{21}_D$ 9.94° in $(CHCl_2)_2$ (*c* 3.371). VII, m. 173-4° (decompn.) on rapid heating. VIII, $[\alpha]^{19}_D$ -60.14° (H_2O, *c* 2.112); tetraacetate, m. 83-4°, $[\alpha]^{21}_D$ -27.25° in $(CHCl_2)_2$ (*c* 5.412). From 5 g. VII allowed to attain mutarotation equil. in a slight excess of HCl and then acetylated were obtained 3 g. pure β-IV, m. 119-20°, $[\alpha]^{20}_D$ 10.9° in $(CHCl_2)_2$, and a small quantity of a highly purified α-IV, m. 126-7°, $[\alpha]^{20}_D$ 120.2° in $(CHCl_2)_2$ (*c* 0.416). **XIII. Addition of acetobromoglucose to thioureas: S-glucosido-*ps*-thioureas.** WILHELM SCHNEIDER AND KURT EISFELD. *Ibid* 1260-3.—Derivs. of an isomer (I) of Fischer's and Helferich and Kosche's thiourea glucoside (II) (*C. A.* **20**, 1595) are obtained when acetobromoglucose (III) is heated in a suitable solvent with $CS(NH_2)_2$. The III adds like a simple alkyl halide with primary formation of a thiuronium salt derived from a *ps*-thiourea with the acetylated sugar residue substituted on the S. PhNHCSNH$_2$ behaves in the same way but it has thus far not been possible to carry out the reaction with $CS(NHPh)_2$ and allylthiourea gives only amorphous, non-homogeneous products. Nor could the free glucothiosides be obtained from the Ac derivs. with NH_3 in MeOH, as they are decompd. by the NH_3-MeOH with formation of glucothiose. *Tetraacetyl-ps-thiourea S-d-glucoside-HBr* (*tetraacetyl-d-glucosido-S-thiuronium bromide*), $Ac_4C_6H_7O_5SC(NH_2)(:NH).HBr$ (37% from III in boiling PhMe slowly treated with powd. $CS(NH_2)_2$), m. 192°, $[\alpha]^{20}_D$ -8.72° (H_2O, *c* 5.102); 1 g. dissolves in 10 cc. H_2O and 7.5 cc. alc.; *bicarbonate*, $C_{16}H_{24}O_{12}N_2S$, from the bromide in cold H_2O with $NaHCO_3$, sinters 84°, m. 92° (foaming), soon weathers in the air but loses most of its CO_2 only *in vacuo* over absorbents, yields in H_2O at room temp. in 20-30 hrs. an amorphous product which from its compn. is apparently a decompn. product of the tetraacetylthioureaglucoside. *Primary oxalate*, m. 159° (decompn.). *Tetraacetyl[monophenyl-ps-thiourea]-S-d-gluco-*

side (50% from III refluxed in C_6H_6 with $PhNHCSNH_2$, extd. with aq. HCl and neutralized with $NaHCO_3$), m. 150°; 1 g. dissolves in 30–5 cc. boiling alc.; it is pronouncedly basic, dissolving in dil. HCl and being repptd. unchanged by $NaHCO_3$; in $(CHCl_2)_2$ it is optically inactive while in AcOEt (*c* 1.410), it shows $[\alpha]^{22}_D$ 19.15°. *Primary oxalate*, $[\alpha]^{20}_D$ —15.55° (50% alc., *c* 1.994). C. A. R.

Pectin substances. III. Chemical composition of pectins. Kazimierz Smoleński and Wanda Włostowska. *Roczniki Chem.* **7**, 591–611(1927); cf. *C. A.* **19**, 41; **20**, 2519; **21**, 3603—Sugar-beet pulp whose detailed analysis is given contains about 71% pectin substances. They were detd. with the aid of their "characteristic groups:" ash, pentosans, hexuronic acids, galactosides and galacturonic groups (as mucic acid), MeOH, acid and ester nos., volatile acids (AcOH), detd. by vacuum distn. with H_3PO_4 to dryness followed by vacuum-steam distn., org. acids (ash dissolved in excess acid and titrated with Me orange), protein (Kjeldahl). Galacturonides and arabans are extd. by the "usual" method which consists in heating 100 g. pulp 3 hrs. on the water bath to 95–7°, with 2 l. water and 62 cc. *N* HCl (the "theoretical" amt. of HCl obtained by titration with Congo red is 50 cc.), straining and neutralizing to Congo with Na_2CO_3. The soln. is evapd. to 20% solids and the *galacturonides* are pptd. by adding 400 cc. 90–5% alc. per 100 g. soln., and purified by dialysis against water. The filtrate contains araban, which is sepd. by vacuum evapn. The total ext. obtained is 42–3%. The O_2, H_2 and C contents of galacturonides obtained by this method from sugar beet, common beet and carrot are practically the same. The compn. of the arabans (arabinose, reducing sugars, $[\alpha]$) of the common and sugar beet resemble each other closely. A variation of acid concn., temp. and time will, however, cause a marked variation in quantity and compn. of the exts. As the hydrolysis becomes more energetic the content of arabans in reducing and *d*-rotatory sugars increases, while the galacturonides show an increasing content in arabans and "undetd. substance," which is galactan. The araban-free part of a galacturonide obtained by 3 hrs.' heating to 70–5° with 90% of the "theoretical" HCl pretty closely approaches the theoretical formula of a *Ca-Mg salt* of *Me acetyldigalacturonate*. The analyses confirm the formula originally attributed to *protopectin:* $(C_6H_8O_6.C_6H_7O_6.OMe)_n$ + $(C_6H_{10}O_5)_n$ + $(C_5H_8O_4.C_5H_8O_4.C_5H_8O_4)_n$. The galacturonide obtained by heating with distd. water to 90–5° has a similar compn. but contains only 0.5 the quantity of AcOH. The analysis sheds no light on the question whether galacturonide, araban and galactan are originally attached to each other. At any rate the bonds must be very weak. The araban bonds range next in instability, since water- and even alc.-sol. products are obtained already by heating with slightly acidulated water. Galactose is hydrolyzed by higher concns. and the products are insol. in 75% alc. Pure galacturonide becomes easily water-sol. but it is insol. in 75% alc., and is very resistant to further hydrolysis. The identity of the "undetd. substance" with galactan is borne out by the following facts: The ultimate products of galacturonide hydrolysis with HCl contain galactose, in quantities approximately corresponding to that of the undetd. substance. Galacturonide contains neither glucose nor glucuronic acid and the products of hydrolysis are free from fructose and mannose. The ester no. corresponds with the Me and AcOH content only in the case of the almost pure galacturonide. For the products of more energetic hydrolysis it is, for reasons unknown, considerably higher. **IV. Acid hydrolysis of galacturonide and araban.** *Ibid* 611–27—Galacturonide obtained by the "usual" method was subjected to fractional hydrolysis on the water bath: (*a*), 10 hrs. with 0.05 *N* H_2SO_4; (*b*), like (*a*); (*c*), 5 or 10 hrs. with 0.25 *N* H_2SO_4 or 5 hrs. with 0.5 *N* H_2SO_4. (*a*) splits off the MeOH, AcOH and some of the galactan and galacturonic acid, although in a more complex form. (*b*) splits more araban and galactan and liberates hexuronic acids. (*c*) completes the hydrolysis of the sugars and splits the remainder of araban, which seems to be more firmly attached and more resistant to hydrolysis to arabinose than the araban split by (*a*) and (*b*). It also yields a galacturonide, (I), sol. in 75% alc. contg. 90–5% *hexuronic acid* and perhaps some araban. Its mol. wt. (ebullioscopic) was 1115 and 912. $[\alpha]_D$ 216°. The analysis corresponds fairly well with $(C_6H_8O_6)_n$. The detn. of its characteristic groups suggests that it is the *mono-Ca digalacturonate*, $(C_{12}H_{16}O_{12}ca)_n$, where n = 3 or 4. It is easily sol. in hot and cold water, insol. in 70% alc. The aq. soln. is slightly acid to Congo, strongly to litmus. Mineral acid does not cause a ppt., NaOH produces a greenish color, $Ba(OH)_2$ and $Pb(OH)(AcO)$ give voluminous jelly-like yellowish green ppts. Of the *araban* the part contained in the galacturonic acid is not completely sepd. from it even by 10 hrs.' heating with 0.25 *N* H_2SO_4 and resists hydrolysis to arabinose by far more than the larger portion of araban, the hydrolysis of which begins already at 0.1–0.05 *N* H_2SO_4. The *l*-rotation decreases with increasing

reducing power until it reaches that of pure arabinose: 100° to 105°. From the partly hydrolyzed solns. the [α] of pure araban is calcd. to be —200° to —220°. From the [α] of I the [α] of pure, araban-free galacturonide is calcd. to be 250°. **V. Alkaline hydrolysis of galacturonide.** *Ibid* 628–36.—The addn. of 150 cc. *N* NaOH to 25 g. galacturonide obtained by the "usual" method in 250 cc. splits off MeOH and AcOH, leaving *Na pectate*, which contains as much galacturonic acid, araban and galactan as the original galacturonide. Part of the araban and galactan is split off by the addn. of moderately concd. HCl. Four hrs.' heating with *N* H_2SO_4 leads to a galactan-free substance with 90% galacturonic acid. This *polygalacturonic acid* $(C_6H_8O_6)_n$ differs from I in that it is very difficultly sol. in water and does not reduce Fehling's soln. $[\alpha]_D$ 250°. Heating with a large excess of MeOH contg. 0.7% HCl to 100° yields about 50% *Me ester*, which was not isolated. **VI. Products of complete hydrolysis of galacturonide and araban.** *Ibid* 636–55.—*d-Galacturonic acid*, $C_6H_{10}O_7.H_2O$, obtained by heating pectic acid 2.5 hrs. to 125–30° with 0.1 *N* H_2SO_4, pptg. the Ba salt from alc., decompg. with H_2SO_4 and crystg. from 70–80% alc., m. 110–2° (the m. p. rises to 158–9°, on continued rapid heating), [α] 49.9°. It shows mutarotation. The reducing power of the anhyd. acid is less than 80%, the quantity of mucic acid obtained by oxidation with HNO_3 about 85% of the values for galactose. The *galacturonide* proper contains 11.5% AcOH (1:2 mols.), and 7% MeOH, the "usual" product 5–5.5% AcOH and 5.5% MeOH. Both are easily sapond. by alkali, MeOH less easily by acid. There is also a trace of a volatile Ag-reducing acid, probably *glyoxylic acid*. *d-Galactose* is found among the products of acid hydrolysis of pectic acid and has been identified as its *o*-tolyl-, α-methylphenyl- and α-benzylphenylhydrazone. It was also obtained by fractional acid hydrolysis of the "usual" galacturonide and by energetic hydrolysis of galacturonide proper. In the latter case it was also identified by fermentation tests (*S. cerevisiae* and *S. pombe*). The acid hydrolysis of the (easily split) *a-araban* yields arabinose, identified by its crystals, [α] and hydrazones. It is also obtained by the hydrolysis of galacturonide, *i. e.*, from the resistant *b-araban*. **VII. Composition and constitution of pectin substances.** *Ibid* 655–77.—Beet pulp contains: *Arabangalactangalacturonide* (I), which is the polymeric *Ca Mg salt* of the *mono-Me arabangalactanacetyldigalacturonate*, $(C_{26}H_{38}O_{22})_n$ araban a, and as products of hydrolysis of I araban b, galactan and galacturonide proper. MARY JACOBSEN

Oxidation of carbohydrates, fats and nitrogenous products by air in presence of sunlight. C. C. PALIT AND N. R. DHAR. Allahabad Univ. *J. Phys. Chem.* **32,** 1263–8(1928).—Solns. of galactose, arabinose, cane sugar, glucose, levulose, lactose, maltose, starch, glycogen, urea, glycine, α-alanine, hippuric acid, Na urate, K stearate, K oleate, K palmitate and $K_2C_2O_4$ are oxidized when air is passed through them in presence of sunlight. The presence of a photosensitizer, such as ZnO, promotes oxidation. The bearing of these oxidations on the *use of sunlight in preventing deficiency diseases* is discussed. R. E. GIBSON

The reducing properties of methylated sugars. GEZA ZEMPLÉN. *Matematik. Természettudományi Ertesitö* **43,** 101–9 (Hung.), 110 (Ger.), (1926); cf. *C. A.* **20,** 1221.—The detn. of the structure of disaccharides according to the method of Irvine requires considerable quantities of material (20–30 g.). By a method based on the large differences which exist in the reducing properties of the various methylated disaccharides, the structure of the sugar can be detd. with a 0.1-g. sample. The practicability of this method was demonstrated with gentiobiose and cellobiose. J. S. REICHERT

Gentiobiose and its relation to amygdalin. GEZA ZEMPLÉN. *Matematik. Természettudományi Ertesitö* **42,** 292–8 (Hung.), 299 (Ger.) (1926); cf. *C. A.* **18,** 2891; **19,** 73, 276.—It is assumed that the synthesis of *amygdalin biose* is effected by means of amygdalin emulsin. The biose of amygdalin is identical with gentiobiose, since the *octamethylgentiobiose* gives the same products of hydrolysis as maltose. The complete synthesis of amygdalin was accomplished by converting dextrose by means of emulsin into gentiobiose, which was converted first into the octa-Ac compd. and then into *acetobromogentiobiose*. The latter with silver *l*-mandelate gives *heptaacetylgentiobiose mandelate* and *heptaacetylamygdalinic acid*. The lactone or the ester of this acid with NH_3 gives the amide, which with $POCl_3$ gives *heptaacetylamygdalin*. J. S. R.

New isocellotriose. H. OST. *Z. angew. Chem.* **41,** 696–8(1928).—The product of the acetylation of cotton cellulose by Ost and Prosiegel (*C. A.* **14,** 3656) contains in addn. to the cellotriose recently described (*C. A.* **21,** 3456) an *isocellotriose*, present in the portion freely sol. in alc. and [illegible]

crystn. (lost at 115–20°), forms no osazone, has no sweet taste, and is not fermented by yeast. It is only slowly hydrolyzed to dextrose by 2.5% HCl, conversion being incomplete after 8–10 hrs. and considerable amts. of humic substances formed. Acetylation with Ac_2O and $ZnCl_2$ affords an *undecaacetate*, m. 120–50°, $[\alpha]_D$ 2.4° ($CHCl_3$), which is somewhat more sol. than the similarly prepd. *undecaacetate* of the isomeric cellotriose, m. 200–20°, $[\alpha]_D$ 2.2 to 6.2°, the latter being contaminated with a little of the octaacetates, m. 222° and 192°, of the isomeric cellobiose. *Isocellobiose acetate*, m. 115–25° $[\alpha]_D$ 4° ($CHCl_3$), was similarly prepd. from isocellobiose, being much more readily sol. than the cellobiose octaacetate, m. 220°, which is also formed. B. C. A.

Benzylation and phenylation of 2-methylcyclohexanone. R. Cornubert and H. Le Bihan. *Compt. rend.* **186**, 1126–8(1928); cf. *C. A.* **22**, 1960, 3146.—When 2-methylcyclohexanone is treated with sodamide and benzyl halides under conditions calcd. to produce monobenzylation, there are produced benzyl-2-methylcyclohexanones, b_{17} 167–9° (chief product), 2,6-dibenzyl-2-methylcyclohexanone, m. 105° (also formed by hydrogenation of the benzylidene deriv. of 2-benzyl-2-methylcyclohexanone), and an isomeride of the last-named compd., b_{16} 230–2°. The mixt. of benzyl-2-methylcyclohexanones affords 6-benzylidene-2-benzyl-2-methylcyclohexanone, m. 80–1° (HCl additive compd., m. 124°), and the pyrone-like compd., m. 191°, already prepd. from 6-benzyl-2-methylcyclohexanone (C. and Borrel, *C. A.* **20**, 3456). From the latter results it is calcd. that the benzyl-2-methylcyclohexanones contain 9% and 10–11% of the 2,6-isomeride when prepd. by the use of $PhCH_2Br$ and $PhCH_2Cl$, resp. B. C. A.

A new iodosobenzene (iodoso-iodoxybenzene) electrode and its application for the determination of p_{OH} and p_H. Feliks Grossman. *Roczniki Chem.* **7**, 567–78 (1927).—The construction of the iodosobenzene electrode (I) is analogous to that of the quinhydrone electrode. Formulas for calcns. are evolved. I was compared with a H_2 (II) and a quinhydrone electrode (III) for a no. of fluids the p_H of which ranged from 1 to 13. For p_H 4.6, 6 and 7 the ratio of potentials I/II was 1.420, I/O_2 electrode (as calcd. from I/III) 0.190. The ratios gradually decrease on both sides of this range, until they reach the same values for p_H 1 and 13: 1.362 and 0.133, resp. The p_H obtained with the aid of I, II and the HgCl electrode agreed pretty well with each other for solns. ranging from 0.1 *N* HCl to 0.1 *N* NaOH. The potential of I is established in 5 min. and is fairly stable for acid solns. (for 0.1 *N* HCl it varied within a week from 1.060 to 1.064), less so for alk. solns. Mixts. of PhIO and $PhIO_2$ in the proportions of 1:1 to 1:10 gave practically the same results as I. A further increase of $PhIO_2$ resulted in a lower and less rapidly established potential. The potential of the *iodoxybenzene electrode* was considerably smaller and was established very slowly, so that consistent results were not obtained, possibly because of contamination with PhIO. The reaction underlying the potential of the electrode is: $PhIO + 2OH^- - 2(-) = PhIO_2 + H_2O$. It may be subdivided into 3 phases: $PhIO + H_2O = PhI(OH)_2$. $PhI(OH)_2 + 2OH^- - 2(-) \rightleftharpoons PhI(OH)_4$; $PhI(OH)_4 = PhIO_2 + 2H_2O$. The formulas were based on this equation assuming $[PhIO_2]/[PhIO] = 1$. But probably collateral reactions take place which are not accounted for in the formulas. Mary Jacobsen

Catalytic preparation of alkylanilines. I. Bankim Chandra Ray. Univ. College of Science, Calcutta. *J. Indian Chem. Soc.* **5**, 383–6(1928).—The prepn. of MeNHPh and Me_2NPh, with thoria as a catalyst, is studied. A mixt. of $PhNH_2$ (I) and MeOH (II), gave only 40% conversion when passed at 440° over thoria prepd. by burning the oxalate. Asbestos purified by digesting with HCl was soaked with $Th(NO_3)_4$ soln. and heated until decompn. of the nitrate was complete. Over this catalyst a mixt. of I and EtOH gave 67% conversion at 390°. A mixt. of I and II over this same catalyst at 430° gives 75% conversion. The quantity of unconverted I is detd. by diazotizing the product and then titrating with a known vol. of R salt. D. H. Powers

The action of light on diazo derivatives. A. Seyewetz and D. Mounier. *Bull. soc. chim.* **43**, 827–38(1928).—See *C. A.* **22**, 2373. E. H.

Optically active α-arsonocarboxylic acids. H. J. Backer and C. H. K. Mulder. *Proc. Acad. Sci. Amsterdam* **31**, 301–3(1928).—See *C. A.* **22**, 2364. E. H.

Reduction of aromatic nitro compounds in the presence of magnesium chloride. Stanislaw Micewicz. *Roczniki Chem.* **8**, 50–4(1928).—The following compds. were prepd.: *p*-toluidine, m. 44–5°, by 3 hrs.' heating on the water bath of 30 g. $MgCl_2.6H_2O$ (I) in 20 cc. water, with 10 g. *p*-$C_7H_7NO_2$ and 15 g. Fe (Ferrum reductum Merck). *o*- and *p*-aminophenol, m. 172° and 184°, by 0.5 hrs.' heating of 15 g. I, 20 cc. water, 5 g. nitrophenol and 15 g. Fe. Yield 80%. *m*-$C_6H_4(NH_2)_2$ by refluxing 5 hrs. 10 g. $C_6H_4(NO_2)_2$ in 75 cc. acetone with 75 g. I in 75 cc. water and 30 g. Fe. Yield 70%. *p*-$C_6H_4(NH_2)_2$, m. 138–9°, by refluxing 4–5 hrs. 10 g. nitroaniline in 75 cc. acetone with 75 g. I in 75 cc. water and isolating as the HCl salt. The grass-green intermediate

formed in the beginning soon disappears The *o*- and *m*-compds. can be reduced in the same manner. 1,2,4-Dinitrotoluene resisted reduction. The ease of reduction decreases in the following order: nitrophenols, nitroanilines, nitrobenzenes. Attempts at the isolation of jelly-like, sometimes colored intermediates which are probably compds. of the amine and $MgCl_2$ were unsuccessful. MARY JACOBSEN

Presence of *o*-arsanilic acid in technical arsanilic acid. N. P. POZDNYAKOV. *J. Chem. Ind.* (*Moscow*) **5,** 530(1928).- It is known that *p*-arsanilic acid which is prepd. by the action of H_3AsO_4 on $PhNH_2$ contains Ph_2AsO_2H as an impurity (cf. Benda, *C. A.* **2,** 2938; Kober and Davis, *C. A.* **13,** 1858). P. found that it also contains *o*-arsanilic acid in fairly large quantity. The presence of the latter impurity is particularly undesirable, since arsphenamine obtained from arsanilic acid contg. it would contain some *o*-arsphenamine, the properties of which are not well known. To sep. *o*- from *p*-arsanilic acid P. recommends a method which is founded on the greater soly. in water of the former 100 g. of water dissolves at 16.5° 2.801-2.875 g. of *o*-arsanilic acid, whereas the same quantity of water dissolves at 15.5° only 0.390 g. of *p*-arsanilic acid. 100 g. of triturated technical 84% arsanilic acid is agitated in a mixing app. with 900 cc. water at 15-17° for 6 hrs., after which the undissolved residue of *p*-arsanilic acid is filtered and the filtrate is concd. to 100 cc. by evapn. on a steam bath Crystals of *p*-arsanilic acid ppt. on cooling and are filtered off, while the filtrate is concd. to 40-50 cc. to ppt *o*-arsanilic acid. BERNARD NELSON

Organo-antimony compounds. II. The constitution of *p*-aminostibonic acid and its amine salts. SUDHIR CHANDRA NIYOGY. Univ. College of Science, Calcutta. *J. Indian Chem. Soc* **5,** 285-91(1928); cf *C. A.* **22,** 1148.—A study is made of the constitution of the salts of the arylstibonic acids. *p*-$AcNHC_6H_4NH_2$ diazotized at 0° in HCl was treated with aq $SbCl_3$ to give a white insol product. Drying this product over soda lime 2 days, and warming with NaOH until N_2 evolution ceased gave 4-aminophenylstibonic acid (I), which must be preserved in aq. suspension. I with aq. $MeNH_2$ gave, after warming 5 min., $(NH_2C_6H_4SbO_3H_2)_3MeNH_2$. The following *salts* were also prepd and in every case had 3 mol of the stibonic acid to one of the base, thus confirming Schmidt's contention: Me_2NH, Me_3N, $EtNH_2$, Et_2NH, Et_3N, $PrNH_2$, *iso*-$AmNH_2$, and $AmNH_2$. D. H. POWERS

A new method of preparing organo-mercury compounds of phenols, phenol ethers and aromatic amines. P. NEOGI AND MANAS P. CHATTERJI. Presidency College, Calcutta. *J. Indian Chem Soc* **5,** 221-9(1928). It was shown by Neogi (*C. A.* **21,** 1398) that glycerol (I) greatly increases the period of induction in the interaction of $HgCl_2$ (II) and $NaHCO_3$ (III) Aromatic phenols or amines are added to this mixt during the period of induction and offer a new method for forming Hg compds. To PhOH (10 g.) in H_2O with I (10 cc.) is added an aq. soln. of II (6 g.). On addn. of a soln. of III a yellowish ppt. seps., which changes to white when dil. HCl or strong NaCl is added. It is found to be a mixt of *p*-HOC_6H_4HgCl, m. 219°, and the *o-isomer* m. 133°. Similarly catechol (4 g.) with I (10 cc.), II (16 g.) and III (5 g.) gives *o*-$C_6H_4(OHgCl)_2$, decomps. 150° Resorcinol (5 g.) with 15 cc. of I, 20 g. of II and 6 g. of III gives *m*-$C_6H_4(OHgCl)_2$, decomps 210°. Orcinol similarly gives 1,3,5-$MeC_6H_3(OHgCl)_2$, decomps. 210°. Guaiacol (3 g.) in alc. with 20 cc. of I is mixed with an aq. soln. of III (2 g.) and an aq. soln of II (6 g.) is slowly added to give *o*-$MeOC_6H_4OHgCl$, decomps. 130°. Phloroglucinol gives 1,3,5-$C_6H_3(OHgCl)_3$, decomps. 160°. Quinol gives *p*-$C_6H_4(OHgCl)_2$, decomps. 160°, but this product is not pure because oxidation caused the formation of quinone and consequently HgCl and Hg, and the product could not be purified because of its insoly With amines I is not necessary. To $PhNH_2$ (3 g.) in alc. with 3 g. of III in H_2O is added a hot aq soln. of II (9 g.) to yield the insol. yellow PhNHHgCl. PhNHMe gives PhNMeHgCl, decomps. 108°. $PhNMe_2$ in alc. was mixed with aq. III, and alc II was added and the mixt. allowed to stand 2 hrs. to give *p*-mercurodiphenylenetetramethylmercurodiammonium chloride. D. H. POWERS

Preparation of dimethylaminodiaryl sulfones. ERICH GEBAUER-FÜLNEGG AND PAUL SCHWARZ. Univ. Wien. *Ber.* **61B,** 1307-8(1928).—Like Bergel and Döring (*C. A.* **22,** 2555), G.-F. and S. have found that the compds. described by Michler as sulfones are really sulfonic acid methylanilides and they have devised a simpler and more generally applicable method than B. and D.'s for the prepn. of the true dimethylaminodiaryl sulfones. Arylmono- and polysulfonyl chlorides are made to react in the presence of $AlCl_3$ as in the condensation of sulfonyl chlorides with aromatic ketones, the simultaneous formation of Me violet being prevented as far as possible by controlling the temp. exactly, which can advantageously be done by using an appropriate solvent. *E. g.*, *4'-dimethylamino-4-methyldiphenyl sulfone*, m. 212°, and *4-dimethylaminodiphenyl sulfone*, m. 178°, were obtained by boiling 10 g. *p*-$MeC_6H_4SO_2Cl$ ($PhSO_2Cl$), 2 mols.

$PhNMe_2$ and 1 mol. $AlCl_3$ in CS_2 for about 2 hrs. A report on dimethylaminophenyl sulfones of the $C_{10}H_8$, $C_{10}H_7OH$ and $C_6H_4(CO)_2C_6H_4$ series, their use as dyestuff components and deviations in the course of the reaction will be made elsewhere.

Bromoiodophenols produced from 5-bromo- and 3,5-dibromosalicylic acids. P. Brenans and C. Girod. *Compt. rend.* **186**, 1128–30(1928).—I reacts with 5-bromosalicylic acid (Hewitt, Kenner and Silk, *J. Chem. Soc.* **85**, 1228(1904); also produced from 5-aminosalicylic acid by the diazo reaction) in the presence of NaOH or Na_2CO_3 to afford 4,2,6-$BrI_2C_6H_2OH$, m. 128° (Et ether, m. 75°), which when heated with aq. Na_2CO_3, is converted into an amorphous red compd. of unknown constitution. 3,5-Dibromosalicylic acid, when treated with less than 1 mol. of I under similar conditions, yields 2,4,-6-$Br_2IC_6H_2OH$, m. 104° (Et ether, m. 54°), which is transformed into a red compd. when treated with an excess of I in aq. Na_2CO_3. B. C. A.

Chloroiodophenols obtained from 5-chloro- and 3,5-dichlorosalicylic acids. P. Brenans and C. Girod *Compt. rend.* **186**, 1553–5(1928).—I in the presence of NaOH reacts with 5-chlorosalicylic acid to afford 4,2,6-$ClI_2C_6H_2OH$, m. 108° (*Et ether*, m. 69°; *Ac deriv.*, m. 127.5°). In a similar way 3,5-dichlorosalicylic acid yields 2,4,6-$Cl_2IC_6H_2OH$, m 63° (*Et ether*, b. 290 4°; *Ac deriv.*, m. 66°). B. C. A.

Constitution of some dinitro-*m*-cresols. Shrirang M. Sane and Shiam Sundar Joshi. Lucknow Univ. *J. Indian Chem. Soc.* **5**, 299–301(1928).—A study is made to det. the constitution of some dinitro-*m*-cresols. *m*-MeC_6H_4Cl with H_2SO_4 and HNO_3 gives 3,4,6-$Cl(O_2N)_2C_6H_2Me$, m. 91°, which on fusion with $AcNH_2$ and NaOAc at 180° for an hr. gives the 3-HO compd. (I), m. 71°. I with *p*-$MeC_6H_4SO_2Cl$ (II) and with Et_2NPh (III), at 100° for 4 hrs. gives 4,6-dinitro-*m*-tolyl *p*-toluenesulfonate (IV), m. 110 1°. IV in xylene satd with dry NH_3 for one hr. gives 3,4,6-$H_2N(O_2N)_2C_6H_2Me$, m. 194°. I in HOAc with Br_2 gives 2,3,4,6-$Br(HO)(O_2N)_2C_6HMe$ (V), m. 115 6°. V with II and III at 100° for 6 hrs. gives 3,2,4,6-$ClBr(O_2N)_2C_6HMe$, m. 81–2°

Condensation of pyruvic acid with aromatic aldehydes and amines. II. St. Weil and Fr. Goldberg. *Roczniki Chem.* 7, 585–90(1927).—See *C. A.* **22**, 2152. M. J.

Mechanism of the reaction between pyrocatechol and phosphorus trichloride. Ludwig Anschütz and Walter Broeker. Univ. Marburg. *Ber.* **61B**, 1264–7(1928); cf. *C. A.* **21**, 2461.—Knauer (*Ber.* **27**, 2569(1894)) had found that *o*-$C_6H_4(OH)_2$ (I) and PCl_3 give $C_6H_4O_2PCl$ (II) and $(C_6H_4:)_3(PO_3)_2$ (III) and A. and B. have now succeeded in isolating an intermediate product, *o-phenylene o-hydroxyphenyl phosphite*, $C_6H_4O_2POC_6H_4OH$ (IV). The process therefore probably consists of 3 successive bimol. reactions: I + PCl_3 = II + 2HCl; II + I = IV + HCl; IV + II = III + HCl. K.'s method of prepn. of II gives only very poor yields; treatment of III with PCl_3 at 160° is much more satisfactory. **II**, like other ester chlorides of sym H_3PO_3, can add S at high temps.: II + S (at 195°) → $C_6H_4O_2PSCl$ (V). **IV** (5–7 g. from 22 g. I refluxed with PCl_3 in C_6H_6, protected from the air), b_{12} 155°, m. 112–3° very sensitive to atm. moisture, evolves HCl with AcCl, the resulting product decompg on distn. *in vacuo*; with II at 120°, it yields **III**. **II**, m. 30°, b_{10} 80°. *Pyrocatechylphosphorus thiochloride* (V), m. 49–50°, b_1 106°, mol. wt. (Rast) 208. C. A. R.

Synthesis in the propenylphenol series. L. V. Douau. *Parfumerie moderne* **7**, 320–3(1927); **8**, 18–21, 210–4(1928).—A review. A. Papineau-Couture

The ethylenic isomerism of the β-*p*-tolylbenzalacetophenones. Marius Badoche. Coll. de France, Paris. *Bull. soc. chim.* **43**, 337–43(1928).—Usually prepn. of a compd. with an ethylene bond does not give the 2 isomers. Dufraisse states that the constitution of the compd. rather than the method of prepn. dets. whether both stereoisomers will be formed. In the prepn. of *β-p-tolylbenzalacetophenone, p-MeC₆H₄CPh:CHCOPh* (I), both isomers are formed. Probably the presence of both isomers is not due to transmutation, for transmutation gives mixts. less rich in the labile isomer than does prepn. The methods of prepn of I were the isomerization of *p*-$MeC_6H_4CPh(OH)C:CPh$ (II) and the removal of HBr from *p-tolylphenyl-α-bromopropiophenone, p-MeC₆H₄CHPhCHBrCOPh* (III). Into cold EtMgBr (4 g. Mg + 19 g. EtBr) is poured 17 g. HC : CH in 17 cc. Et_2O; the mixt is heated later on the H_2O bath, then cooled and treated gradually with 31.5 g. *p*-MeC_6H_4COPh in 35 cc. Et_2O then boiled 1 hr. This gives 46.7 g. of **II** b_{6-7} 205°. **II** (47 g.) in 360 cc. 96% EtOH with 40 cc. H_2SO_4 (66° Bé), heated 1 hr., gives upon cooling a product (I) which is washed with $NaHCO_3$, H_2O and EtOH; yield 36 g., m. 63–110°, and 3.3 g. additional from the mother liquor; I is a mixt. of 2 stereoisomers, *A*, lozenges, sometimes large rhombohedric crystals and *B* fine needles, often grouped in tufts. Crude I, dissolved in EtOH with the aid of heat and allowed to crystallize for 48 hrs. in the refrigerator, gives *A* as huge crystals

and *B* as fine needles which are dissolved out of the cryst. residue by warm EtOH. More *A* is obtained similarly from the mother liquors. *A*, recrystd. from EtOH, m. 109.5–10.5°. *B* is extd. from the residues after the removal of *A* by the method of Dufraisse (*C. A.* **16**, 2327); *B* m. 85–6°, but changes spontaneously and melts much lower after several days. *B*, suspended in EtOH and exposed to sunlight, becomes almost wholly *A;* upon boiling *B* in alc. with HCl (but not with HOAc) the result is the same. *A*, heated at 120–30° for 10 min in a sealed tube with a particle of I, changes into *B* to the extent of 10%. From p-MeC_6H_4MgBr (6.7 g. Mg + 48.5 g. p-MeC_6H_4Br) and 40 g. PhCH:CBrCOPh in 50 cc. ether, added drop by drop, is obtained 48 g. of III; purified with an alc. ether mixt., III m. 134–5°. III (8 g.) and 10 g. quinoline heated 0.25 hr. at 185–90°, give 6 g. of a mixt. of *A* and *B*. III and pyridine, heated 3 hrs. at 130–40°, lost 37% of its Br and gave a poorer yield of *A* and *B* than in the above case. MARGARET W. MCPHERSON

Saccharin. HUBERT VAN ROOST. *Bull. trimestr. assocn. élèves école sup. brasserie univ. Louvain* **28**, 49–61(1928).—A review. A. PAPINEAU-COUTURE

Action of organic magnesium compounds on cinnamic acid anilides. N. MAXIM AND N. IOANID. Univ Bucarest. *Bull soc. chim. Roumania* **10**, 29–48(1928).—RMgBr on PhCH:CHCONEt$_2$ gives $PhCHRCH_2CONEt_2$ (I) instead of a ketone as is the case with satd. aromatic amides. By hydrolysis with HBr I gives PhCHR-CH_2CO_2H (*C. A.* **22**, 2153). EtMgBr and PhMgBr react quant. with *N*-substituted cinnamic acid anilides to give satd. *N*-substituted acids. The ethyl-, methyl- and phenylanilides have been prepd. by the action of PhCH:CHCOCl on the corresponding amines. PhCH:CHCONMePh (II), b_{15} 231°, m. 70°, and EtMgBr (III) give β-phenylvaleric methylanilide, b_{12} 206°. PhMgBr (IV) on II gives β,β-diphenylpropionic methylanilide, b_{13} 261°. With III, the ethylanilide, b_{16} 234°, m. 46°, gives β-phenylvaleric ethylanilide, b_{16} 214°; with IV it gives β,β-diphenylpropionic ethylanilide, b_{25} 278°. The phenylanilide, m. 156°, with III gives β-phenylvaleric phenylanilide, b_{18} 268°, m. 52–3°; with IV it gives β,β-diphenylpropionic phenylanilide, m. 130°. MeMgI (V) reacts weakly with cinnamic acid anilides and gives exclusively the corresponding ketone and amine. PhCH·CHCONRPh (VI) and MeMgI give PhCH:-CHCOMe and HNRPh. These satd. anilides hydrolyze easily with 40% HBr to give the corresponding satd. acids. The reaction of III and IV on the anilides is still unexplained. The reaction with V is as follows: V and VI form PhCH:CH(CMeOMgI)-NRPh, this with water gives PhCH:CHC(OH)MeNRPh, then PhCH:CHCOMe and HNRPh. This is in contradiction with Thiele's theory of partial valences. M. and I. conclude V reacts contrary to Thiele's theory. The reaction between III, IV and the cinnamic acid anilides is not known. 3- and 4-addn are theorically possible; expts. only can settle which takes place. By the action of III and IV on cinnamic acid anilides, satd. anilides are obtained quant.; these hydrolyze to give satd. acids. V reacts on cinnamic acid anilides to give a small quantity of benzylideneacetone. This cannot be considered a practical method because of the low yields. Detailed exptl. data are given for the prepn. of the products mentioned. By hydrolysis with HBr, β-phenylvaleric methyl- and ethylanilides give $EtCHPhCH_2CO_2H$, m. 66°; β,β-diphenylpropionic methyl- and ethylanilides give $Ph_2CHCH_2CO_2H$, m. 155°; $EtCHPhCH_2CONPh_2$ gives a mixt. of $EtCHPhCH_2CO_2H$ and $NHPh_2$; $Ph_2CHCH_2CONPh_2$, a mixt. of $Ph_2CHCH_2CO_2H$ and $NHPh_2$. P. THOMASSET

Photobromination of *m*-nitrobenzylidenemalonic ester. II. JNANENDRA C. GHOSH, KALI P. BASU AND SUDHIR C. BHATTACHARYYA. Dacca Univ. *J. Indian Chem. Soc.* **5**, 183–90(1928); cf. *C. A.* **22**, 1151.—The photobromination of m-O_2N-C_6H_4CH:$C(CO_2Et)_2$ in CCl_4 is studied under the same conditions as outlined previously in the study in CS_2 soln. There was practically no reaction for 24 hrs. in the dark. The equil. which is given by [dibromide]/[Br] × [ester] is detd. by the temp. and intensity of radiation. It is noted that the ratio of the equil. consts. (1.55) is equal to the ratio of the square roots of the corresponding incident intensities (1.45). Varying the intensity of radiation and temp. gives 1.8 and 2.1 for the temp. coeff. of k_1 and the equil. const. K_2 at 32° is 78.0. It is shown that the equil. const. is dependent on the intensity of the illumination and in the initial stages of the reaction the velocity of photobromination is proportional to the concn. of Br_2 and increases with decreasing concn. of ester. The equil. const. in CCl_4 is 7 times its value in CS_2 and the velocity of bromination is about 7 times its rate in CS_2 and the decompn. of the dibromide proceeds further and more quickly in CS_2. D. H. POWERS

Amides of thio- and dithiosalicylic acid. ARNOLD REISSERT AND ERICH MANNS. Univ. Marburg. *Ber.* **61B**, 1308–16(1928).—o-$HOC_6H_4CONH_2$ by the Schotten-Bauman method gives not only the *N*-Bz deriv. $HOC_6H_4CONHBz$ (I), m. 208°, but

also a di-Bz deriv. (in C_5H_5N even a tri-Bz deriv. is formed), whereas in the presence of Na_2CO_3 instead of NaOH is obtained the *O*-Bz isomer, $BzOC_6H_4CONH_2$ (**II**), m. 144°, which at first does not dissolve in NaOH but on standing does dissolve with yellow color and rearranges into **I**, which explains why it is not obtained by the S.-B. method. It was of interest to det. how *o*-$HSC_6H_4CONH_2$ (**III**) would behave on benzoylation. It is probable that the action of alkalies on aromatic disulfides can be represented by the equation PhSSPh + 2KOH = PhSK + PhSOK + H_2O, the PhSOK then oxidizing to $PhSO_2K$. Accordingly, (*o*-$H_2NCOC_6H_4S)_2$ (**IV**) with NaOH should give $H_2NCOC_6H_4SNa$ and $H_2NCOC_6H_4SONa$ (**V**) and such is the case, but the **V** at once forms *α,β-benzisothiazolone* (**VI**), $C_6H_4.CO.NH.S$; along with it are obtained the mercaptan and disulfide, the latter formed from the former by spontaneous oxidation or by the oxidizing action of the non-anhydrized **V**. The **VI** can be obtained without by-products by adding Br to **IV** and then removing HBr (best with boiling AcOH) from the resulting $H_2NCOC_6H_4SBr$. The *N*-Me and *N*-Ph derivs. of **VI** were similarly obtained from the *methylamide* and anilide of $(HO_2CC_6H_4S)_2$. H_2O_2 oxidizes the $C_6H_4.CO.NR.S$ to the corresponding saccharins, $C_6H_4.CO.NR.SO_2$. The Ag salt of **VI** with MeI gives the *N*- and *O-Me* derivs. On benzoylation **IV** reacts as would be expected from its behavior with alkalies; by the Schotten-Baumann method it gives the Bz deriv. of **VI**, also obtained from the Na salt of **VI** with BzCl, and a Bz deriv. (**VIII**) of **III** which, by analogy with $H_2NCOC_6H_4OH$, should be the *N-Bz deriv* formed by rearrangement of the *S*-deriv. (**VIII**). **VII** could not be isolated as such but its presence was shown by its oxidation with air to $(BzNHCOC_6H_4S)_2$. **VIII** is obtained by boiling with BzCl in C_6H_6 suspension the dry Na salt of **III**, prepd. from **IV** with Zn dust. When the benzoylation of **IV** by the S.-B. method is carried out with an excess of BzCl and NaOH, there are formed, together with the Bz deriv. of **VI**, the *di-* and *tri-Bz derivs.*, $BzNHCOC_6H_4SBz$ (**IX**) and $Bz_2NCOC_6H_4SBz$ (**X**), of **III**. **IX** is also obtained by boiling **X** with AcOH. *o*-$PhNHCOC_6H_4SH$ (**XI**) with NaOH and excess of BzCl gives a mixt. of the *S-Bz* (**XII**) and *di-Bz* (**XIII**) *derivs.* **XII** is also obtained by boiling the dry Na salt of **XI** with BzCl in C_6H_6 and is not oxidized to a disulfide by the air. With alkalies (*o*-$PhNHCOC_6H_4S)_2$ (**XIV**) gave **XI**, as expected, but the Ph deriv. of **VI** could not be obtained in large enough quantity for purification by this method. (*o*-$MeNHCOC_6H_4S)_2$, from the chloride and $MeNH_2$ in boiling C_6H_6, m. 216.5°. **VI** (1.6 g. from 2 g. **IV** treated with Br in CCl_4 and subsequently boiled with AcOH), m. 157–8°, sol. in alkalies and repptd. unchanged, even after boiling, by acids. *N-Ph deriv.* (3.6 g. from 4 g. **XIV** with Br and then boiling AcOH), m. 143–4°. *N-Me deriv.*, m. 54°; *HBr salt*, m. 216° (decompn.); *HCl salt*, m. 130° (decompn.). *O-Me ether* (*3-methoxy-α,β-benzisothiazole*), liquid volatile with steam. *N-Bz deriv.*, m. 167°. **XII**, m. 135°. *N,N'-Dibenzoyldithiosalicylic diamide*, m. 191°. **IX**, m. 135°, mol. wt. (Rast) 365.3. **X**, m. 220–2°, **XII**, m. 140°, **XIII**, m. 614°. C. A. R.

Constitution of fraxetin. F. Wessely and E. Demmer. Univ. Wien. *Ber.* **61B**, 1279–84(1928).—Fraxetin (**I**) had been shown to be a methoxydihydroxycoumarin but the position of the substituents was not known. Prepd. by hydrolysis of fraxin with dil. H_2SO_4 or HCl on the H_2O bath, it turns yellow 150° and m. 227–8°. With CH_2N_2 it gives almost quant. the di-Me ether, m. 103–4°, $b_{0.2}$ 90–100°, prepd. by Korner and Biginelli with MeI. Heated with 2 atoms Na in abs. MeOH at 100°, then with 3 mols. MeI, this ether yields a $(MeO)_4C_6HCH:CHCO_2Me$, hydrolyzed by 2 mols. boiling *N* NaOH to the free acid which, neutralized with *N* NaOH and oxidized with a quantity of $KMnO_4$ equiv. to the NaOH used, yields *2,3,4,5-tetramethoxybenzoic acid* (**II**), m. 87.5°, identical with the product obtained from 2,5,3,4-$(MeO)_2(HO)_2C_6HCO_2H$ (**III**) and CH_2N_2. *Diethylfraxetin*, from **I** and $MeCHN_2$, m. 81–2°, treated with Na in MeOH and then with MeI as above gives a *Me dimethoxydiethoxycinnamate*, m. 62–74°; the free acid on oxidation gives *2,5-dimethoxy-3,4-dihydroxybenzoic acid*, m. 83°, identical with the product obtained from **III** with $MeCHN_2$. The **III**, m. 146–7°, is obtained in 50% yield from apiolic acid, 2,5,3,4-$(MeO)_2(CH_2O_2)C_6HCO_2H$, heated on the H_2O bath with 2 mols. *m*-$C_6H_4(OH)_2$ and concd. H_2SO_4. **I** must, from the above results, have the structure MeOC═CH—C.CH:CH.

The application of the Hoesch reaction to nitrobenzonitriles. MASATARO YAMASHITA. Tohoku Imp. Univ., Sendai. *Bull. Chem. Soc. Japan* **3**, 180–2(1928).—To 3 g. *p*-$O_2NC_6H_4CN$ (I) and 2.5 g. resorcinol (II) in 150 cc. abs. Et_2O, 2 g. freshly fused and powd. $ZnCl_2$ was added, and dry HCl passed into the soln. for 5 hrs. at room temp A brownish red oil sepd. The soln. was allowed to stand overnight, the Et_2O decanted, the oil washed with Et_2O and boiled with 50 cc. H_2O for 30 min. There was thus obtained 0.9 g. of 4′-nitro-2,4-dihydroxybenzophenone (III), pale yellow, m. 203° (200° given by Korczynski and Nowakowski *Bull. soc. chim.* **43**, 329). Other substances prepd. by the same method were *3′-nitro-2,4-dihydroxybenzophenone* (IV), from *m*-$O_2NC_6H_4CN$ (V) and II, yellow, m. 228°; 4′-nitro-2,4,6-trihydroxybenzophenone, from I and phloroglucinol (VI), yellow, m. 246–7° (244–5° given by K. and N.); *3′-nitro-2,4,6-trihydroxybenzophenone*, from V and VI, yellow, m. 194°. The *Me deriv.* of III, prepd. by shaking III in 10% NaOH with Me_2SO_4, was pale yellow and m. 123–4°; *Me deriv.* of IV, m. 116–7°. *o*-$O_2NC_6H_4CN$ could not be condensed with either II or VI. Y. plans to use the compds. obtained by means of this reaction for the prepn. of derivs. of Ph_2CO contg. various substituents in the benzene nucleus. LOUISE KELLEY

Colored hydrocarbons of the rubrene family. ANTOINE WILLEMART. *Compt. rend.* **187**, 385–7(1928); cf *C. A.* **22**, 3889.—In the transformation of R′R″C(OH)C:CR‴ (I) into a rubrene hydrocarbon through the HCl ester, the nature of the R′, R″ and R‴ groups exercises a very important influence on the reaction. The results have been negative with aliphatic groups, and favorable with tolyl or $C_{10}H_7$ groups only when such groups were in the R‴ position The mechanism suggested by W. for the reaction is as follows: After the formation of R′R″CClC:CR‴ from I, the Cl migrates, giving an intermediate allene compd., R′R″C·C:CClR‴, not yet isolated. This undergoes cyclization, forming an unstable cyclic allene deriv., which is at once transformed with rearrangement of the bonds, into a dimer. This theory explains the difficulty of obtaining the hydrocarbon sought when R′ and R″ are different. The reaction product contains instead of 1 substance, the 2 isomeric hydrocarbons formed from the cyclization by R′ or by R″, and their extn. is almost impossible. When R′ and R″ are $C_{10}H_7$ groups, the skeleton of the mol. is markedly changed, and it is not surprising that the reaction follows a very different course. A $C_{10}H_7$ group in the R‴ position modifies the skeleton least, and it is therefore possible in this case to obtain the corresponding rubrene. The formula proposed by W. is also in accord with the strong coloration of these hydrocarbons and their unusual properties. L. K.

Action of bromine on azomethine derivatives of fluorene. ARMANDO NOVELLI. *Anales asoc. quím. Argentina* **15**, 423–9(1927).—Graebe (*Rev. chim. pura applicada* 1889) studied the action of Br on dibenzofulvenes, finding that diphenylenedibenzofulvene (bisdiphenyleneëthene) fixes 2 Br atoms to form a colorless Br_2 deriv., $(C_6H_4.C_6H_4.CBr)_2$. Thiele and Henle (*Ann.* **347**, 290(1906)) obtained the corresponding Br_2 deriv. of phenyldibenzofulvene. It is interesting to det. if in the dibenzofulvene imides Br acts similarly to form a colorless Br_2 deriv. with azomethines (*C. A.* **22**, 775). The action of Br on Schiff bases is very similar to that with azomethines studied by Hantzsch (*Ber.* **23**, 2774(1890)), who tried Br on PhCH:NPh, obtaining PhCHBrNBrPh, which H_2O decomps. very readily to BzH and *p*-$BrC_6H_4NH_2$. This suggests fixing Br not directly on the double bonds but in the *p*-position to form *p*-BrC_6H_4CH:NPh.HBr. The Br atoms are very labile and the derivs. obtained are sol. in anhyd. solvents. If the solvent contains H_2O the compd. is decolorized at once by decompn. The anhyd. soln. attacks Cu or Au to form bromides, but if the solvent contains H_2O these metals are not attacked. Decompn. thus occurs in contact with H_2O with migration of the Br atoms. Berg (*C. A.* **19**, 2645) studied under similar conditions the addn. products of Br on Schiff bases differing as to the aldehydes and amine bases used in their prepn. He found the Br addn. products to be cryst. yellow powders or orange liquids insol. in C_6H_6, CS_2 or ether, generally very sensitive to light. When the amine is aromatic 1 Br atom is found on the amine nucleus; the other forms HBr on decompn., regenerating the aldehyde. The azomethines studied by N., derivs. of 2,7-dibromofluorene condensed with *p*-$ONC_6H_4NMe_2$ (cf. *C. A* **22**, 775), when in contact with Br give addn. compds. of the general formula: $C_6H_3Br.C_6H_3Br.CBrNBrC_6H_4NMe_2$. 1.78 g. of the azomethine in ice-cold CS_2, is slowly treated with the theoretical quantity of Br (0.005 mol.) in

CS_2, giving a violet ppt. and a red liquid, allowed to stand 12 hrs., filtered, washed with boiling CS_2, giving a yellow powder decompg. readily with H_2O to form 2,7-dibromofluorenone, m. 210°. Tests with metallic Ag or Au show that before hydrolysis the 2 Br atoms are attached to the $>C:N.C:N$ group, since if they were on the C_6H_6 nucleus they would have insufficient lability to combine with the metal. E. M. S.

Diaminotriphenylmethane and the like (preliminary communication). HUGO WEIL, EUGEN SAPPER, E. KRÄMER, KARL KLÖTER AND HANS SELBERG. Lab. Dr. H. Weil, München. *Ber.* **61B**, 1294–1307(1928).—All the methods of prepg. $(H_2NC_6H_4)_2$-CHPh (I) hitherto described give poor yields. In all of them the quantity of $PhNH_2$.-HCl used is far too large, resulting in a phenylation of the I formed primarily. When the quantity of $PhNH_2$.HCl is materially reduced not only are excellent yields obtained but after heating only about 45 min. at 130–40° the $PhNH_2$ addn. product (II) seps. on cooling in large crystals. According to Werner Ph_3CH also seps. from $PhNH_2$ with 1 mol. of the solvent but the present authors have found repeatedly that when the crystals are washed with alc. to disappearance of the $PhNH_2$ odor, the resulting Ph_3CH, m. 92°, is entirely free of $PhNH_2$. II, m 126°, is quite stable and can be recrystd. unchanged from alc.; steam removes the $PhNH_2$ only very slowly and incompletely and only after addn. of NaOH can all the $PhNH_2$ be driven off, the remaining I m. 139° after crystn. from Et_2O. Pure I can also be obtained without the use of org. solvents by converting the crude base into the sulfate, which is difficultly sol in H_2O as well as alc., and decompg. the salt with NH_4OH On recrystn. from C_6H_6, the $PhNH_2$ is replaced by C_6H_6 and the C_6H_6 addn. product (III) seps. and, conversely, III changes into II on recrystn. from $PhNH_2$. The same change is effected, although not so completely, by long standing in the cold, the I sepg. with 1 mol. of that of the 2 substances ($PhNH_2$ or C_6H_6) which is present in larger quantity. If I, II and III, resp., are treated in cold AcOH with Ac_2O, I gives the di-Ac deriv. (IV), m. 240–1°, quant. in 4 hrs.; III at the end of this time only begins to deposit crystals which rapidly increase in quantity to about $^2/_3$ the calcd. on rubbing, the yield becoming nearly quant. after a short time; II, generally, gives not a trace of crystals in 4 hrs. even when the soln. is seeded, and the sepn. of IV is approx. complete only after about 24 hrs. This is not due merely to a difference in soly. IV dissolves no more readily in AcOH-Ac_2O contg. corresponding quantities of $PhNH_2$ or PhNHAc than in the AcOH-Ac_2O alone. These reactions have been repeated hundreds of times, always with the same results, whether the acetylation had been effected in AcOH or abs. alc. Only when the soln. of II in the AcOH-Ac_2O is poured into C_6H_6 does IV begin to sep. as quickly as when III is used; if it is poured into H_2O before the crystals have begun to sep., the AcOH dissolves and there seps. as an oil a soln. of the base (and probably the mono-Ac deriv.) in Ac_2O; the acetylation continues in spite of the surrounding H_2O, the oil slowly becoming tarry and finally hard, and boiling alc. then extg. from it acetylation products m. 187° to 233°. Pouring into dil. HCl also does not interrupt the acetylation, once it has been started, and in fact I or II in aq. HCl can be acetylated to IV with Ac_2O in the cold; in this case there is no difference between I and II in the velocity of acetylation. The diminished reactivity of the NH_2 groups in II can also be shown, although not so markedly, with other reagents. With 1 mol. HCHO I gives the anhydro compd. in 1, II in 2.5–3 min.; as the quantity of HCHO is increased the differences in reaction velocity become less but are still distinct. BzH behaves in the same way It is not surprising, therefore, that II is more weakly basic than I although it contains 1 more salt-forming group; II in AcOH is hydrolyzed when poured into H_2O and about 20% of it crysts. out, whereas I under the same conditions remains in soln. To explain these mol. complexes and especially their hindering influence on the reactions of the I the conception of partial valences does not suffice. A more satisfactory explanation is that it is the accumulation of C_6H_6 and $PhNH_2$ nuclei in the I which attracts the extra C_6H_6 or $PhNH_2$ mol. like the force between 2 bodies with elec. charges of the same sign but different magnitudes which are brought together mechanically. This does not exclude the possibility that there are still other forces, *e. g.*, forces such as those between 2 charged bodies with opposite polarities. It has thus far not been possible to obtain a $PhNMe_2$ addn. product of leucomalachite green (V) but it is a well-known fact that $PhNMe_2$ cannot be completely sepd. from V by steam distn. unless alkali is added. On the other hand, if leucomethyl violet (VI) solns. in 5 parts hot $PhNMe_2$ are cooled the quantity of crystals which sep. decreases with time and the filtrates, which still contain about 0.5 of the VI, give only minimal ppts. with MeOH, a fact which might be explained by the formation of a $PhNMe_2$ compd. more sol. than the VI itself. The crystals, carefully washed with MeOH, m. 173° like VI but when large quantities are fused the distn. of $PhNMe_2$ in droplets can be distinctly observed;

with steam, nothing distils from these crystals but if alkali is added or, better, if they are dissolved in HCl and then treated with alkali, a strong odor of $PhNMe_2$ at once develops and about 10% of the quantity of $PhNMe_2$ calcd. for 1 mol. distils off. Between the extremes II and V.$PhNMe_2$ lie intermediate substances. Thus *o-chlorodiaminotriphenylmethane* (VII) yields a well-crystd. $PhNH_2$ compd., which, however, loses its $PhNH_2$ on crystn. from alc. The C_6H_6 compd of *m-nitrodiaminotriphenylmethane* (VIII) is slowly acetylated and its di-Ac deriv holds 1 mol. AcOH so firmly that even crystn. from alc. does not completely remove the AcOH. The attraction of I for $PhNMe_2$ is materially less than that for $PhNH_2$; I holds only 0.5 mol. $PhNMe_2$. *m-* and *p-chloro-* and *o-*, *m-* and *p-hydroxytriphenylmethanes* and their C_6H_6 and $PhNH_2$ compds. have been prepd.; the latter behave on acetylation like the C_6H_6 and $PhNH_2$ compds. of I (with p-$HOC_6H_4CH(C_6H_4NH_2)_2$ no Ac deriv. seps. because it is too sol.). In the three HO compds., no acetylation of the HO group occurs even in boiling Ac_2O. I combines with other aromatic bases having no occupied *p*-position (o-$ClC_6H_4NH_2$, o-$MeC_6H_4NH_2$, m-$C_6H_4(NH_2)_2$), also with C_5H_5N, piperidine and tetrahydroquinoline, but not with o-$C_6H_4(NH_2)_2$, the three $O_2NC_6H_4NH_2$ and $H_2NC_6H_4CO_2H$, the two $C_{10}H_7NH_2$, Ph_2NH and $PhCH_2NH_2$. It also combines with a large no. of non-basic substances (PhMe, PhCl, o-ClC_6H_4Me, thiophene, PhOH, cresol and the constituents of naphtha but not *p*-disubstituted compds. nor m-ClC_6H_4Me, PhCN, Ph_2, $PhSO_3H$ and nitrated hydrocarbons). In the presence of enough $PhNH_2.HCl$ I is phenylated by $PhNH_2$ at 130-40°, as shown by the evolution of NH_3 and by the production of a green color on oxidation of the product; it has not been possible to obtain the latter in cryst. form but its compn indicates that it is a mono-Ph deriv. *o-Toluidine compd* of I, m. 130°; III, m. 106° only on rapid heating, the m. p rising up to around 130° the more slowly the compd. is heated; *PhMe compd.*, m. 100-1°. *Aniline compd.* of VII, m. 92-3°; *benzene compd.*, m. 79°; *PhMe compd.*, m. 73°. *Aniline compd.* of p-$ClC_6H_4CH(C_6H_4NH_2)_2$, m. 109°; *benzene compd.*, m. 96-8°. VIII, m 157°; *aniline compd.* (26 g. from 10 g. m-$O_2NC_6H_4CHO$, 33 g. $PhNH_2$ and 14 g. $PhNH_2.HCl$ at 140°), brown, m. 108°; *benzene compd.*, light yellow, m. 76°; *di-Ac deriv.*, crystals with 1 AcOH, m. 166° (loss of AcOH), then solidifies and m. again 204°. o-HOC_6H_4-$CH(C_6H_4NH_2)_2$, m. 150°; *aniline compd.* (16 g. from 10 g. o-HOC_6H_4CHO), m. 125°; *benzene compd.*, m. 76°; *di-Ac deriv*, m. 187°. m-$HOC_6H_4CH(C_6H_4NH_2)_2$, m. 172°; *aniline compd.* (24 g. from 10 g. m-HOC_6H_4CHO), m. 138°; *benzene compd.*, yellow, m. 106° (loss of C_6H_6) and again 172°; *sulfate; di-Ac deriv.*, m. 216°, sol. in dil. alkalies. p-$HOC_6H_4CH(C_6H_4NH_2)_2$, m. 178°; *aniline compd.* (yield, about 70%) faintly reddish, m. 153°; *benzene compd.*, m. 121° (loss of C_6H_6) and again 178°; *di-Ac deriv.*, m about 194°, sol. in alkalies. *Compds.* of I with: *m-chloroaniline*, m. 92°; *m-phenylenediamine*, m. 46.5°; *dimethylaniline*, I.0.5$PhNMe_2$, m. 142.5°; *pyridine*, m. 142°; *PhCl*, m. 108-9°; *o-chlorotoluene*, m. 108-12°; *thiophene*, sinters 86°, m. 110° (effervescence) and again 139°; *PhOH*, m. 110°; *o-cresol*, m. 97-8° (?) (97-89° in the original.—Abstr.); *piperidine*, m. 112-6°. C. A. R.

New iodo derivatives of phthaleins. Frederick R. Greenbaum. *Am. J. Pharm.* **100**, 374-85(1928).—The 2 different isomers of *tetraiodophenolphthalein*, α and β, were prepd., the former by the well-known method of Classen and Loeb (*Ber.* **28**, 1610(1895)) and the latter by fusing $C_6I_4(CO)_2O$ prepd. according to D. R. P. 50,177, Jan. 1889 (*Friedländer*, **1**, 93), with phenol. The α-isomer is an amorphous white powder, insol. in cold or hot H_2O and insol. in acids, sol., however, in hot EtOH, in ether and other org. solvents and sol. in dil. alkalies with a blue color which disappears on addn. of more alkali. It decomps. 220°, giving off vapors of I. Analysis for I gave 61.6% (calcd 61.8%). Di-Na salt of the β-isomer gave 57.75% I on analysis (calcd. for $C_{20}H_8O_4I_4Na_2$, 58.6% I). The free β-compd. is an amorphous powder insol. in cold or hot H_2O, insol. in all common org. solvents but sol. in alkalies with a pink to a reddish color which disappears on addn. of strong alkalies. From this compd. the *octaiodophenolphthalein* was prepd. as follows: 20 g. of the β-tetra-I compd. in excess alkali was treated with 72 g. of I in 84 g. of 20% NaOH with stirring and then heated to boiling, gradually acidified by adding in a fine stream glacial AcOH, with const. stirring, boiled for 0.5 hr., neutralized with NaOH, then rapidly acidified with HCl, again heated to a boil, allowed to settle, decanted, and filtered; the ppt. was washed with H_2O until free from acid, redissolved in NaOH, $NaHSO_3$ added and the soln. acidified, which pptd. the I compd. and at the same time liberated SO_2 from the $NaHSO_3$, this removing any free I included in the ppt. of octa-I compd. The ppt. was then filtered off, washed thoroughly with H_2O until free from acid or any other impurities and dried in a vacuum desiccator to const. wt. The analysis gave 76.25% for I (calcd. 76.60%). The compd. is a yellow cryst. substance insol. in cold or hot

H_2O, easily sol. in dil. alkalies, the soln. having a faint greenish color. On account of its high mol. wt. (1326) and its high content of I it is particularly suitable for experimentation in choleocystography. For the next iodophthalein prepd., 40 g. of dinitrophenolphthalein in 40 g. of 20% NaOH and 300 g. of H_2O was boiled and filtered, then mixed with 120 g. of unsublimed I in 140 g. of 20% NaOH and 300 g. of H_2O and slowly treated with 125 g. of glacial AcOH with stirring. This liberated I in a finely suspended state and the substitution then took place. The mixt. was boiled for about 0.5 hr., then 85 g. of 20% NaOH was added to neutralize the AcOH, and the soln. was rapidly acidified with 125 g. concd. HCl and 125 g. of H_2O, boiled for a short time, allowed to settle, the supernatant I soln. decanted, the ppt. washed with hot H_2O, filtered and washed again with H_2O until the wash H_2O was almost colorless. Then the ppt. was dissolved in dil. NaOH. filtered and pptd. with concd. HCl. This ppt. was filtered off and redissolved in NaOH, repptd. and washed free from HCl. If necessary $NaHSO_3$ was added before acidifying it, and then HCl added; this removes the free I present. This yellow ppt. of *diiododinitrophenolphthalein* was thoroughly dried on a steam bath and then in a desiccator. It is a light yellow amorphous powder, m. 249-50°, insol in cold and hot H_2O, sol. in NaOH with an orange color, insol. in the usual org solvents, sol. in glacial AcOH. The next higher homolog of phenolphthalein, *viz.*, fluorescein, was nitrated according to Beilstein, 2, 2064(1896 ed). The introduction of I into the resulting dinitrofluorescein gave a new deriv., *dinitrodiiodofluorescein*, $C_{20}H_8O_9N_2I_2$, which was prepd. in exactly the same way as the phthalein This method of introduction of I as described above proved satisfactory in all fluorescein derivs. and in many other phthaleins. *Diiododinitrofluorescein* is an orange-red amorphous powder insol. in cold and hot H_2O, sol. in EtOH and MeOH and sol. in ether, sol. in NaOH with a blue color and repptd. on acidification. From *m*-cresolphthalein prepd. in the same way as *o*-cresolphthalein (*Beilstein*, 2, 1987(1896 ed.)), *diiodo-m-cresolphthalein* was obtained in the following manner: 10 g. of *m*-cresolphthalein was dissolved in an excess of NaOH, filtered, treated slowly with 20 g. of I and 20 g. of KI in 100 cc. of H_2O with stirring for 2 hrs., acidified with HCl, filtered, washed, redissolved in NaOH and repptd. with HCl. This procedure was repeated twice, and the ppt. filtered and washed with H_2O to free it from HCl and dried on a steam bath. The *di-I-compd.* is a brown amorphous powder, m. 214°, insol. in cold and hot H_2O, insol in ether, somewhat sol. in EtOH and MeOH, very slightly sol. in dil. NaOH; on heating it dissolves with dark brown color. It is interesting to note that this exhaustive method for introduction of I does not furnish a tetra-I deriv. as would be expected, but only a di-I compd. in spite of the fact that the 4 *o*-positions are not occupied. The next compd. tried was rhodamine B, the com. compd. available in tetraethyldiaminophenolphthalein-HCl. This rhodamine B was treated by 2 methods for the introduction of I. The direct addn. of I in KI to an alk. soln. of rhodamine B resulted in a monoiodorhodamine (calcd. N 4.90, I 23.3; found 4.6, 22.7%). It is of course clear that this is an unsatd. compd. but every attempt to introduce more I by the use of this method failed. At last the following method was tried and resulted in a *diiodorhodamine B:* To 2.2 g. of highly purified rhodamine B in 200 cc. of H_2O, 2.3 g. of ICl_3 in 100 cc. of H_2O contg. 10 cc. of concd. HCl was added. Immediate pptn. of a reddish flocculent compd. occurred. This was filtered off and washed with H_2O until all the acid was removed, then dried and analyzed: calcd. N 4.0, I 36.4; found 3.9, 36.3%. It is a reddish brown powder, somewhat sol. in cold and hot H_2O, insol. in dil. alkalies, insol. in acids, very sol. in ether, in MeOH and in EtOH. The last phthalein which was included in this study was thymolphthalein. 8.6 g. in 8.0 g. of boiling 20% NaOH and 60 g. of H_2O, was treated with 24 g. of I in 28 g. of 20% NaOH and 60 g. of H_2O, boiled for 0.5 hr., AcOH added, the soln. boiled again, neutralized with NaOH, acidified with HCl, boiled and filtered and the ppt. purified and dried on a steam bath and in a desiccator. In spite of this vigorous I-introduction method only a mono-I compd. resulted, and attempts to use ICl_3 and ICl resulted in the same mono-I compd. as the analysis shows (found, 23.96% I). *Monoiodothymolphthalein* is a brown amorphous powder insol. in cold or hot H_2O, sol. in common org. solvents, sol. in alkalies with a blue color. W. G. Gaessler

Mercuration of naphthalene derivatives. Jerzy Krynski. *Roczniki Chem.* 8, 71-87(1928); cf. Dimroth, Ueber direkte Einfuehrung von Quecksilber in aromatische Verbindungen, Tuebingen, 1900; Pesci, *Rend. accad. Lincei* [5], 1, 312 (1928).—The mercuration was carried out by heating equimol. parts of the org. compd. and Hg salt: (*a*) in AcOH with $Hg(OAc)_2$; (*b*) in NaOH with freshly pptd. $Hg(OH)_2$ and isolation as acetate; (*c*) by melting together without a solvent in the open or sealed tube until H_2S ppts. a white sulfide. *1-Hydroxy-2,4-diacetatomercuri-*

naphthalene, m. 140°, was obtained by (*a*) from α-naphthol. It yields on bromination *1-hydroxy-2,4-dibromonaphthalene*, m. 105°. Water gradually turns the color to yellow and yellowish green, probably with the formation of *4-acetatomercuri-2-mercuri-1-naphthoquinone*,  or , with 66.67% Hg (calcd. 66.75%). *1-Acetatomercuri-2-hydroxynaphthalene*, m. 168–70°, was obtained by (*a*) and (*b*). It yields on iodination *1,2-I(HO)$C_{10}H_6$*, m. 94.5°. When a stream of CO_2 is passed through the alk. soln. *1-mercuri-2-naphthoquinone*,  (I)  (II), with 58.36% Hg (calcd 58.55%) is formed. II is more probable since the compd. is colorless. When the aq. $Hg(OAc)_2$ and 1,4-$C_{10}H_6(OH)NO_2$ are mixed the red amorphous salt *$C_{10}H_6(NO_2)OHgOAc$* with 44.80% Hg is formed. The yellow cryst. *1-hydroxy-2-acetatomercuri-4-nitronaphthalene* is prepd. by heating the salt or directly by (*a*). It m. 216–8° with explosion. Iodination leads to *1-hydroxy-2-iodo-4-nitronaphthalene*, m. 115°, yellow. 1-Hydroxy-2-nitro-4-acetatomercurinaphthalene, contg 44.94% Hg, yellow, m. 185°, obtained by (*c*) yields on iodination 1-hydroxy-2-nitro-4-iodonaphthalene, m. 145–6°. *1-Acetatomercuri-2-ethoxynaphthalene*, m. 103–4° (47.02% Hg, prepd. by (*c*) from nerolin, yields on bromination *1-bromo-2-ethoxynaphthalene*, m. 66°. H_2S ppts. white needles from the ether soln. probably of *1,1-dimercuri-2,2-diethoxynaphthalene sulfide* $[C_{10}H_6(OEt)Hg]_2S$ (51.67% Hg, 3.93% S; calcd. 51.75% Hg, 4.13% S). *1-Acetatomercuri-2-bromonaphthalene* prepd. by (*c*), light yellow, m. 128–30°, is brominated to 1,2-$C_{10}H_6Br_2$, m. 68°. *1-Mercuriaminonaphthalene*, $C_{10}H_7NHg$, from 1-NH_2-$C_{10}H_7$ by (*a*), m. 203° (decompn.). H_2S splits all Hg off as HgS. 2,2-Dinaphthylamine yields by (*a*) *1,1-diacetatomercuri-2,2-dinaphthylamine*, m. 198°. In 40% AcOH H_2S ppts. a white sulfide which gradually turns black. Attempts at elimination of 1 Hg and ring closure always resulted in the elimination of both Hg. Iodination leads to *1,1-diiodo-2,2-dinaphthylamine*, m. 165–6° (decompn. and liberation of I). Conclusions: The mercuration of naphthols and derivs of naphthylamines and sulfonamides is comparatively easy, that of Cl derivs difficult, that of 1-$C_{10}H_7NO_2$ impossible. The Hg enters in the *o*- or *p*-, never in the *m*-position. The introduction of Hg follows the rules established by Vessely and Jakes (*C. A.* **18**, 253) for Cl, NO_2 and SO_3H. The stability depends on the other substituents. Hg is easily replaced by halogen, which makes the compds valuable intermediates. MARY JACOBSEN

Dioximes. L. G. PONZIO. Univ. Turin. *Ber.* **61B**, 1316–28(1928).—The only recorded exptl. confirmation of the Hantzsch-Werner theory that glyoximes should exist in 4 forms (1 *syn*, 1 *anti* and 2 *amphi*) is the work of Meisenheimer, Lange and Lamparter (*C. A.* **19**, 2819), who report having obtained *p*-$MeOC_6H_4C(:NOH)C(:NOH)$-Ph in 4 forms, m. 206–7°, 176°, 89–91° and 114–5°, resp. They were apparently unaware that P. (*C. A.* **18**, 1490) had described a dioxime of the same structure whose m. p., 223°, was unchanged by recrystn. or by converting the dioxime into its complex Ni salt or di-Bz deriv. and regenerating it with dil. H_2SO_4 or NaOH, resp. Moreover, M., L. and L. prepared their 206–7° compd. by a reaction which also gives the 176° form at the same time, so it is possible their product was impure, whereas the homogeneity of the P. compd. was insured not only by what has been said above but also by the prepn. of an identical product from *p*-$MeOC_6H_4N_2Cl$ and PhC(:NOH)-CH:NOH, a reaction which can give only 1 product. The existence of M., L. and L.'s 3 other products is therefore also doubtful. Moreover, the results of the present work seem to show beyond doubt that the Hantzsch-Werner theory cannot hold for the glyoximes MeC(:NOH)C(:NOH)R (R = Ph, C_6H_4Br or C_6H_4OMe). Of these, only 2 forms had hitherto been known (α and β). The higher-melting β-forms yield complex Ni salts insol. in dil. AcOH and can be obtained by heating the α-forms. Dehydrogenation of the β-dioximes gives 2 peroxides; the higher melting of these on reduction by the Angeli method give exclusively the α-dioximes, while the lower-melting peroxides give exclusively γ-glyoximes which even at room temp. change into the

β-glyoximes. The 2 peroxides are not isomorphous and show entirely different chem. behavior. The higher-melting form on heating changes irreversibly into its isomer, reacts vigorously with PCl_5 with loss of O and formation of the furazan, and is converted by NaOEt into an isomer sol. in bases, while the lower-melting peroxide reacts with neither PCl_5 nor NaOEt and can in no way be converted back into the higher-melting form. Independently of any preconceived notion as to the nature of the isomerism of the glyoximes from which these peroxides are obtained by dehydrogenation and into which they are converted by reduction, P. believes that the higher-melting peroxide is a furoxan (I) and that of the 3 possible formulas for the low-melting isomer

MeC—CAr (O:N.O.N) (I) MeC- -CAr (N.O.O.N) (II)

II is the most probable. Since the β-glyoxime on dehydrogenation yields both the furoxan (I) and the peroxide (II) it should, according to the Hantzsch-Werner theory, have both the *amphi*- and the *syn*-configuration, and the α-glyoxime, which gives II exclusively, should also have the *syn*-configuration. The above facts are readily explained, however, if it is assumed that in the glyoximes 1 of the oximino groups assumes the nitrone form, =N(:O)H, toward certain reagents. The β-glyoxime could then be represented by the equil. MeC[:N(:O)H]C(:NOH)Ar ⇌ MeC(:NOH)C(:NOH)Ar, the α-compd. would be MeC[:N(:O)H]C(:NOH)Ar and the γ-glyoxime MeC(:NOH)C(:NOH)Ar. The β-form of MeC(:NOH)C(:NOH)Ph m. 238–9° (partial sublimation and decompn.). Methylphenylfuroxan (I, Ar = Ph) (5–6 g. (with 2 g. II) from 10 g. of the glyoxime in NaOH with NaOCl or 4–5 g. (with 1 g II) from 10 g. of the glyoxime in Et_2O with N_2O_4), m. 96°, converted by NaOEt in hot alc. into an *isomer*, m. 178–9° (decompn.), sol. in bases. The *peroxide* (II, Ar = Ph), best prepd. by gently refluxing the I in Ac_2O, m. 62°, slowly volatile with steam, sol. without color in concd. H_2SO_4, repptd. unchanged by H_2O, unchanged by boiling alc. NaOEt. The *γ-glyoxime* changes so readily into the β-form that it has not yet been obtained pure; with NaOH-NaOCl it gives II quant Methyl-*p*-methoxyphenylfuroxan (I, Ar = $MeOC_6H_4$), m. 99°; *peroxide*, m. 78°; *di-Bz deriv.* of α-methylanisylglyoxime, m. 157–8°. *Methyl[bromoanisyl]furoxan*, m 109°; *peroxide*, m. 115–6°; alkali-sol. *isomer*, m. 180° (decompn.). *Methyl[nitroanisyl]furoxan*, m. 88°; *peroxide*, m. 112°; furazan, straw-yellow, m. 96–7°. *β-Methyl-[p-bromophenyl]glyoxime*, m. 223–4° (partial decompn.), forms an orange Ni salt insol. in dil. AcOH; *furoxan*, m. 108–9°; alkali-sol. *isomer*, m 179° (decompn.); *peroxide*, m. 88–9°. C. A. R.

Action of ethylmagnesium bromide on acenaphthoquinone. NICOLAS MAXIM. *Bull. soc. chim.* **43**, 769–78(1928).—EtMgBr was prepd. from 8 g. of Mg, 40 g. of EtBr and 100 g. of Et_2O and to this was slowly added 15 g. of *acenaphthoquinone* (I). The mixt. was heated for 4 hrs. and after 12 hrs. the product was poured into cooled 20% H_2SO_4 soln., pptg. *9,10-diethylacenaphthoglycol* (II), m. 197°. By refluxing 1 g. of II in 20 g. of HOAc for 4 hrs. and then adding 5 g. of concd. HCl and a large vol. of water, yellow crystals of *9,10-diethylideneacenaphthene* (III) were formed, m. about 140°. This behavior of II upon dehydration is unlike that of the *di-Ph deriv.*, which yields a pinacolin under this treatment (*C. A.* **4**, 912). III was oxidized to I by boiling 1 g. in 10 g. of HOAc with slow addn. of 6 g. of $Na_2Cr_2O_7$. I crystd. out upon the addn. of H_2O and was purified by dissolving in satd. $NaHSO_3$, filtering and repptg. by heating with dil. H_2SO_4

$C_{10}H_6<(CO)(CO)$ (I) $C_{10}H_6<(CEtOH)(CEtOH)$ (II) $C_{10}H_6<(C:CHMe)(C:CHMe)$ (III)

A. S. CARTER

Synthesis of the indanone of the heliotropin (piperonal) series. FRIGYES KONEK AND MIKLÓS JANOVICS. *Matematik. Természettudományi Értesitö* **42**, 210–21(Hung.), 222–3(Ger.)(1926).—By the Perkin reaction piperonal was converted into the corresponding disubstituted cinnamic acid. The side chain was satd. and by the condensation with P_2O_5 in C_6H_6 the corresponding indanone was prepd. Two structures are possible:

 (I) and  (II)

I was proved correct by the oxidation of the oxime of the indanone into the corresponding methylene ether of phthalic acid which was identical with hydrastic acid prepd. by the oxidation of hydrastinine. J. S. REICHERT

Periodo-alkali salts with organic neutral components. HANS SCHMIDT. Techn. Hochschule Berlin. *Ber.* **61B**, 1347–53(1928).—Löwenbein and S. had observed (*C. A.* **22**, 71) that 3-aryl-3-bromocoumaranones with NaI in Me_2CO liberate I and yield the corresponding free radicals or their association products, the bis-[2-keto-3-aryl-3,3′-coumaranyls], $(C_{10}H_6.O.CO.CPh-)_2$, but on working cautiously there were noted, as intermediate products, intensely green, shimmering needles which rapidly lost I in the air. These green I compds. (I) are the subject of the present study. Pure solns of I and NaI in Me_2CO when evapd. in a vacuum desiccator yield light green needles; concd. solns after a time change into a cryst. magma, also pptd. from more dil. solns. by petroleum ether. The crystals are somewhat lighter in color and smaller and have a much weaker metallic luster than the I; they are also more stable, split off I much less rapidly and become greenish gray in the air; on ignition they leave a residue of NaI and in H_2O dissolve with clear brown color. Analysis indicates that they have the compn. $[(Me_2CO)_6I](NaI)_3$. Hot solns. of I and NaI in AcOH deposit green needles on cooling and concg. To prep the I, the 3-aryl-3-bromocoumaranone in Me_2CO is treated with a concd. (about 15%) soln. of NaI in Me_2CO, filtered from the NaBr and concd. in a vacuum desiccator to a small vol. They must be filtered and washed as rapidly as possible and placed in specimen tubes still moist with Me_2CO. They cannot be dried, forming brown tars in a few min. when spread on clay. All decomp. around 65°. On heating in the air they evolve I vapors and leave a residue of C and Na salt. H_2O, which on boiling splits off all the I and NaI, and solvents decomp. them. They dissolve best in liquids with large dielec consts. The color of the solns. is generally orange-red, especially in ionizing media, which split off little I; with ligroin, there is no soln., yet the violet color of I readily appears. The I can be crystd. only from Me_2CO, best from concd. I-NaI solns. In every case the Na content confirmed the view that the I are NaI addn. products, $(RI)_m(NaI)_n$, of 3-aryl-3-iodocoumaranones formed primarily. The values varied for different compds. and fractions; evidently varying quantities of NaI combine, depending on its concn. Because of the dissocn. of the I in solvents, their mol. wts. could not be detd. with certainty. In the dry state and in soln. they split off I and the resulting free org. radicals combine with each other: $(RI)_2(NaI)_n \longrightarrow 2R\ .\ .\ .\ + I_2 + (NaI)_{2n} \longrightarrow RR + I_2 + (NaI)_{2n}$. Hence, from solns contg much RI and little NaI the dimeric radicals sep. on rubbing with a glass rod, a reaction which can be utilized for isolating the radicals or their assocn. products, especially when other methods fail, $Na_2S_2O_3$ or metals being used to bind the active I. The simple ester-like 3-aryl-3-iodocoumaranones can no more be obtained from the I than from the free radicals, as all NaI solvents also attack the organically combined I. The properties of the I show that they are beyond doubt true salts comparable to the alkali iodide-heavy metal iodide double salts, the alkali metal probably functioning as the cation, $[(RI)_xI]Na$. The following *2-ketocoumaranylperiodosodium compds.* were prepd.: *3-Ph*, $3C_{14}H_9O_2I.2NaI$; *3-phenyl-5-methyl*, $2C_{15}H_{11}O_2I.3NaI$; *3-p-anisyl-5-methyl*, RI.3NaI; *3-phenyl-4,5-benzo*, RI.3NaI, RI.2NaI; *3-p-anisyl-4,5-benzo*, 2RI.3NaI, RI.2NaI. C. A. R.

2,3-Thionaphthene-4-keto-γ-pyran 5,6-dihydride. F. KROLLPFEIFFER AND K. SCHNEIDER. Univ. Marburg. *Ber.* **61B**, 1284–91(1928).—While ring closure in β-phenoxypropionic acids gives the alkali-insol. chromanones, the chloride of *β-[thionaphthenyl-3-oxy]propionic acid* (I) with $AlCl_3$ yields *2,3-thionaphthene-4-keto-γ-pyran 5,6-dihydride* (II), which, although insol. in cold aq. alkalies, dissolves completely with yellow color on gentle warming. Its structure was confirmed by its prepn. from *2-[β-chloropropionyl]-3-hydroxythionaphthene* (III) cautiously treated with 10% Na_2CO_3. A gently warmed alk. soln. of III gives with acids the same compd., *2-[β-hydroxypropionyl]-3-hydroxythionaphthene* (IV), as do alk. solns. of II. While, therefore, the ketodihydropyran ring in the 2,3-benzo derivs. (the chromanones) is quite stable towards alkalies, in II it is easily ruptured. Moreover, unlike the chromanones, whose 3-H atoms are very reactive towards BzH and Br, II forms no benzal deriv. and only with excess of undild. Br does it yield a *mono-Br deriv* (V), whose Br cannot be split off with boiling $PhNMe_2$. On heating with alkali, especially if previously moistened with alc., V dissolves with yellow color and acids ppt. a substance still contg. Br but different from V; its compn. and the behavior of its alc. soln. with $FeCl_3$ (olive-green color) indicate that it is a mono-Br deriv. of IV but lack of material prevented a detn. of its structure; apparently the Br is on the C_6H_4 nucleus. Attempts to synthesize

it from the brominated hydroxythionaphthenes have given no satisfactory results but it was observed in this connection that *o-[ω-bromoaceto]-p-thiocresol Me ether* (VI) changes with extraordinary ease, with loss of MeBr, into 5-methyl-3-hydroxythionaphthene (VII) on heating, either above its m. p. or in solvents (AcOH, PhMe), in fact, on distn. with steam. In the corresponding *I compd.* (VIII) 80% of the I distd. over as MeI in the Zeisel MeO detn. and 13% more was found in the H_2O used for boiling. *o-[α-Bromopropionyl]-p-thiocresol Me ether* (IX) likewise splits off MeI on distn. with steam, forming various substances whose structure has not been detd. As was to be expected from the lesser tendency of the coumaranone ring to be formed *o-[α-bromoaceto]-p-cresol Me ether* (X) distils unchanged with steam and loses no MeBr even above its m. p. I (2.5 g. from 10 g. 3-hydroxythionaphthene (XI) in 45% cold KOH with concd. aq. $ClCH_2CH_2CO_2H$), m. 164–5°. II, b_{12} about 205°, m. 144–5°, sol. in concd. H_2SO_4 with yellow color; *semicarbazone*, m. 229–30°. IV, faintly yellow, m. 129–30°, gives an olive-green color with $FeCl_3$ in alc. and yields with PhNCO a *carbanilate*, $C_{25}H_{20}O_3SN_2$, m. 148–50°. 2-Acetyl-3-hydroxythionaphthene, m. 82°, was obtained from the Me ether of XI and AcCl in CS_2 with $AlCl_3$. *2-EtCO deriv.*, b_{15} 183°, m. 73–4°; *semicarbazone*, faintly yellowish, m. 188–9°. III, m. 121–2°, gives the 2-EtCO deriv. above with Zn dust in boiling AcOH. 2-Bz deriv., golden yellow needles, often with red cryst. aggregates, m. 118–9°; phenylhydrazone, m. 167–8°. V, $C_{11}H_7O_2BrS$. m. 189–90°, sol. in concd. H_2SO_4 with orange color, gives on heating with 2 *N* NaOH and acidifying a substance $C_{11}H_9O_3BrS$, m. 135–6°. VI (with H. Schultze), obtained from 4,2-$MeAcC_6H_3SMe$ and Br in CS_2, yellow, m. 77–8° (with AcOH as the solvent, the product is a halogen-free orange substance m. 226–7°); its soln. in AcOH on refluxing soon becomes red and deposits a small quantity of 5,5′-dimethylthioindigo. VIII, from VI in Me_2CO with KI at room temp., m. 86–7°. *o-Propionyl-p-thiocresol Me ether* (6 g. from 10 g. p-MeC_6H_4SMe with EtCOCl and $AlCl_3$), b_{19} 176–7°, m. 42–3°. IX, faintly yellow. m. 98°. X, m. 74–5°. C. A. R.

Oxidation. I. Action of ferric chloride and hydrogen peroxide on thiosemicarbazones and the synthesis of thiodiazoles and triazoles. SATISH CHANDRA DE AND SATYENDRA K. ROY-CHOUDHURY. Dacca Univ. *J. Indian Chem. Soc.* 5, 269–78 (1928).—Thiosemicarbazones have been oxidized with $FeCl_3$ (I) and H_2O_2 (II) to det. whether mercaptotriazoles are formed. PhCH:NNHC(SH):NH (III) with I gives exclusively 5-phenyl-2-amino-1,3,4-thiodiazole, m. 213–4°. PhCH:CHCH:NNHC(SH):NH with I gives solely *PhCH:CHC:N.N:C(NH₂).S*, m. 260–1°. Salicylaldehyde 4-phenylthiosemicarbazone with I gives *5-salicyl-2-anilido-1,3,4-thiodiazole*, m. 190–1°, *m*-nitrobenzaldehyde phenylthiosemicarbazone gives *5-m-nitrophenyl-2-anilido-1,3,4-thiodiazole*, m. 249–50° (*Ac deriv.*, m. 246°). Further 1,3,4-thiodiazoles similarly prepd. were: *5-p-tolyl-2-phenyl*, m. 198–9° (*Ac deriv.*, m. 155°); *5-p-nitrophenyl-2-p-toluidino*, m. 197–8° (*Ac deriv.*, m. 243°); *5-styryl-2-p-toluidino*, m. 184°; *5-phenyl-2-allylamino*, m. 114–5° (*Ac deriv.*, m. 120°); *5-m-nitrophenyl-2-allylamino*, m. 170–1°; *5-p-nitrophenyl-2-m-toluidino*, m. 257°; *5-phenyl-2-m-toluidino*, m. 176°; *5-m-nitrophenyl-2-o-toluidino*, m. 247–8°; *5-m-nitrophenyl-2-methylamino*, m. 201° (*Ac deriv.*, m 225–6°, *Me deriv.* (using MeI), m. 209°); *5-p-nitrophenyl-2-methylamino*, m. 262° (*Ac deriv.*, m. 279°, *Me deriv.*, m. 203°); *5-o-nitrophenyl-2-m-xylidino*, m. 229°; *5-m-nitrophenyl-2-m-xylidino*, m. 205° (*Ac deriv.*, m. 197–8°); *5-o-nitrophenyl-2-β-naphthylamino*, m. 202°; *5-phenyl-2-ethylamino*, m. 238–40°. III in alc. with an aq. soln. contg. an excess of II gives 5-phenyl-1,3,4-triazole, m. 177°. *o*-Nitrobenzaldehyde 4-*m*-xylylthiosemicarbazone in alc. with II gives *5-o-nitrophenyl-2-thiol-1-m-xylyl-1,3,4-triazole disulfide* (IV), m. 201–3°. The

(IV) (V)

following *2-thiol-1,3,4-triazole disulfides* were similarly prepd.: *5-Ph*, m. 90°; *5-phenyl-1-p-tolyl*, m. 155–6°; *5-phenyl-1-ethyl*, m. 88°; *1,5-diphenyl*, m. 232° (decompn.); *5-m-nitrophenyl-1-allyl*, m. 173°. Acetone thiosemicarbazone in alc. with II gives *2,5-diacetonehydrazido-1,3,4-thiodiazole* (V), m. 260° (decompn.). Similar 1,3,4-thiodiazoles prepd. were the *2,5-diacetonehydrazide-3,4-diphenyl deriv.*, m. 168° (decompn.) and *2,5-diacetonehydrazide-3,4-di-p-tolyl deriv.*, m. 124°. D. H. POWERS

Action of hydrazides. II. Synthesis of some bistriazoles from thiocarbohydrazides. SATISH CHANDRA DE. Dacca Univ. *J. Indian Chem. Soc.* 5, 373–9(1928); cf. *C. A.* 21, 3201.—The action of $CS(NHNH_2)_2$ and $CO(NHNH_2)_2$ on derivs. of phen-

anthraquinone is studied. 2-Bromophenanthraquinone (I) is heated with $CS(NH-NH_2)_2$-HCl (II) in HOAc for a few min. to give *2-bromophenanthraquinonethiocarbohydrazone*, m. 236°. The oxime of I was heated in HOAc for 0.5 hr. with II to give *2-thioketo-bis-5-bromophenanthro-1,2,3-triazole*, m. 145°. 2,7-Dibromophenanthraquinone (III) with II gives the corresponding *hydrazone*, m. 260°. The oxime of III with II gives the *triazole*, m. 210°. 2-Nitrophenanthraquinone with II gives the *hydrazone*, m. 220°, and its oxime gives the *triazole*, m. 200°. The 4-nitro deriv. gives the *hydrazone*, m. 155°. The 4,5-Br_2 deriv. gives the *hydrazone*, m. 270°, and its oxime the *triazole*, m. 235°. The 4,5-$(NO_2)_2$ deriv. gives the *hydrazone*, m. 162°, and its oxime gives the *triazole*, m. 160°. The 2,7-$(NO_2)_2$ deriv. gives the *hydrazone*, m. above 300°, and its oxime gives the *triazole*, m. above 295°. Phenanthraquinone (IV) heated with $CO(NHNH_2)_2$-HCl (V) in HOAc gives *phenanthraquinone carbohydrazone*, m. 285°. The oxime of IV with V gives *2-ketobisphenanthro-1,2,3-triazole*, m. 272°. I with V gives the *hydrazone*, m. 275°, and its oxime with V gives the *triazole*, m. 245°. The 2-nitro deriv. of IV with V gives the *hydrazone*, m. 280°, and its oxime the *triazole*, m. 192°. The 4-nitro deriv. gives the *hydrazone*, m. 240°, and its oxime the *triazole*, m. 200°. The 2,7-Br_2 deriv. gives the *hydrazone*, m. 295°, and its oxime the *triazole*, m. 210°; the 2,7-$(NO_2)_2$ deriv. gives the *hydrazone*, m. above 300°, and its oxime the *triazole*, m. 230°; the 4,5-$(NO_2)_2$ deriv. gives the *hydrazone*, m. 295°, and its oxime the *triazole*, m. 160°; the 4,5-Br_2 deriv. gives the *hydrazone*, m. above 300°, and its oxime the *triazole*, m. 273°.

Cyclic derivatives of acetonedicarboxylic acid. II. Effect of diazomethane on acetonedicarboxylic acid anhydride. J. Litvński and R. Malachowski. *Roczniki Chem.* **7**, 579–84(1927); cf. *C. A.* **21**, 1798.—CH_2N_2 prepd. by Staudinger's method was impure and gave on methylation considerably poorer yields than Pechmann's CH_2N_2 (2.2–2.4 g. from 10 cc. $N(NO)MeCO_2Et$). *4,6-Dimethoxy-α-pyrone*, $C_7H_8O_4$, prepd. by adding dropwise in a freezing mixt. 2.2–2.4 g. CH_2N_2 in ether to 2.7 g. acetonedicarboxylic anhydride (II) in ether (total 150 cc.), m. 105.5–6°, sol. in hot water, alc., $CHCl_3$, scarcely in ether. Yield 80%. The pure I remained several months unaltered. It does not react with enol reagents. I (23 g.) was heated 75 hrs. to 80° with 10 cc. abs. alc., the turbid product was dild. with ether after 12 hrs., decanted from unaltered I and distd. *in vacuo*. *Di-Me β-methoxyglutaconate*, b_{18} 138°, was obtained in 2 g. yield as a highly refractive oil. It is fairly stable to water and begins to give a color with $FeCl_3$ only after prolonged heating. It gives no ppt. with $Cu(OAc)_2$. Methylation of II with 1 mol. CH_2N_2 yields instead of the expected *mono-Me-ether* the diether and unaltered II. *4-Acetoxy-6-methoxy-α-pyrone* (III), obtained by treating 4-acetoxy-6-hydroxy-α-pyrone with CH_2N_2 (yield 70%), m. 66–7°, scarcely sol. in ether and ligroin, easily in other org. solvents, very instable, decomps. within a few days. It is easily sapond. by water instantaneously by Na_2CO_3 and dild. alkali. *4-Hydroxy-6-methoxy-α-pyrone*, $C_6H_6O_4$, (IV), obtained in 70% yield by adding to 14 g. III 100 cc. 2 *N* KOH at 0–5°, filtering rapidly, acidulating with 70 cc. 2 *N* H_2SO_4 at 0° and recrystg. from alc. (rapidly because it reacts), m. 146–7.5°, is hardly sol. in ether (0.120 g. in 100 cc. at 26°), ligroin, $CHCl_3$ and cold water, sol. in hot alc., decompd. by hot water, forms with alkalies and Na_2CO_3 the enolate from which it may be repptd. by acid, gives an orange color with $FeCl_3$, but no lignin reaction. After long standing in AcONa it reacts with PhN_2Cl to CO.O.C(OMe):CH.CO.C·NNHPh, golden platelets, m. 170–1°, sol. in $CHCl_3$ and ligroin. IV is methylated on prolonged heating with MeOH to *di-Me acetonedicarboxylate*, b_{11} 126°; *Cu salt* m. 163–5°. In ether IV reacts only slowly with CH_2N_2 but in MeOH it yields I. The soly. of II in ether is 0.694 g./100 cc. at 26°.

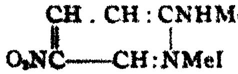
Optical resolution of a spirocyclic compound of the allene type. H. J. Backer and H. B. J. Schurink. *Proc. Acad. Sci. Amsterdam* **31**, 370–1(1928).—See *C. A.* **22**, 3145.

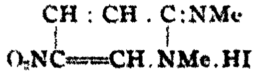
E. H.

Nitro derivatives of methylated forms of α-aminopyridine. II. A. E. Chichibabin and A. V. Kirsanov. *Ber.* **61B**, 1223–35(1928); cf. *C. A.* **20**, 396; **22**, 1975.—The compd. m. 181° (I) obtained from α,β'-$C_5H_3N(NH_2)NO_2$ (II) and MeI had, from analogy with the product obtained from α-$C_5H_4NNH_2$ and MeI, been assigned the structure of β'-nitro-*N*-methylpyridone imide (III), a structure apparently confirmed by the fact that I is also obtained in good yield by the isomerization of *N*-methyl-α-pyridone nitrimide (IV) with H_2SO_4. The formation of I by the isomerization of α-$C_5H_4NNMeNO_2$ was accordingly explained as consisting in a migration of the Me group from the amino N to the ring N. Further study, however, showed that the compd.

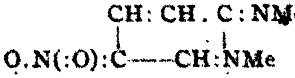
m. 60° (V) obtained by nitration of **I** in cold concd. H_2SO_4, which, from its method of formation, was apparently β'-nitro-*N*-methyl-α-pyridone nitrimide (VI), did not evolve N_2O with alkalies but, on boiling, regenerated **I**. Methylation of α,β'-C_5H_3N-$(NHNO_2)NO_2$ (VII) with alk. Me_2SO_4 yielded **V**, to be sure, but only in small yield, the chief product being an isomer (VIII), m. 182°, which with alkalies gave N_2O and β'-nitro-*N*-methyl-α-pyridone (IX) and which was therefore beyond doubt **VI**. A renewed and thorough study of the reactions of methylated derivs. of **II** and α,β-$C_5H_3N(NH_2)NO_2$ (X) has convinced C. and K. that the migration of the Me group on heating in H_2SO_4 occurs not in α-$C_5H_4NNMeNO_2$ but in **IV** and from the ring to the amino N atom, both α,β'- (XI) and α,β-$C_5H_3N(NHMe)NO_2$ (XII) being formed. There is no doubt that *the presence of NO_2 groups in 1 of the β-positions makes the addn. of MeI on the ring N atom more difficult;* when a Me group is already on the N atom, *the NO_2 group loosens the union of this Me group with the N atom.* Accordingly **II** (and also α,β-$C_5H_3N(NH_2)NO_2$ (XIII)), unlike α-$C_5H_4NNH_2$ itself, gives with MeI almost quant. the MeNH deriv. and not the pyridone imide and **I** is really **XI**. **XI** and **XII** with HNO_2 yield the stable NO derivs. α,β'- (XIV) and α,β-$C_5H_3N(NMeNO)NO_2$ (XV) and are readily brominated to α,β',β- (XVI) and α,β,β'-$C_5H_2N(NHMe)(NO_2)Br$ (XVII). That **XI** and **XII** are methylaminopyridines and not methylpyridone imides is confirmed by the fact that boiling with alkalies gives $MeNH_2$ and not NH_3, with formation of α,β'- (XVIII) and α,β-$C_5H_3N(OH)NO_2$ (XIX), likewise obtained, together with NH_3, from **II** and **X**. α,β'-$C_5H_3N(NMeNO_2)NO_2$ (V) with boiling alkalies first, yields **XI** and then, on longer boiling, **XVIII** and NH_3. When **VIII** is heated with H_2SO_4, not only does the NO_2 group migrate from the imide N but it is also partially split off and the Me group migrates from the ring N atom, so that both α,β,β'-$C_5H_2N(NHMe)$-$(NO_2)_2$ (XX) and **XI** are obtained. On the other hand α-$C_5H_4NNMeNO_2$ gives the same mixt. of **XI** and **XII** as does **IV**; moreover, the HNO_2 formed as by-product gives some **XV**. **V** and α,β-$C_5H_3N(NMeNO_2)NO_2$ (XXI) give **XX**. The difficulty in adding MeI to β-NO_2 derivs. of C_5H_5N is shown by the fact that **XVIII** and α,β'-$C_5H_3NCl(NO_2)$ do not combine with MeI even at 130° although β-$C_5H_4NNO_2$ itself at 100° yields a *methiodide* (XXII), blackens above 190°, m. 203° (decompn.). It is a striking fact that di-NO_2 derivs. of C_5H_4NNHMe and $C_5H_4NNMe_2$ are formed much more easily than that of $C_5H_4NNH_2$ itself; moreover, $C_5H_2N(NH_2)(NO_2)_2$ is formed very much more readily from **X** than from **II**. Again, when **XI** is warmed with MeI there is formed chiefly, together with only a little α,β'-$C_5H_3N(NMe_2)NO_2$ (XXIII) (which is very smoothly obtained by nitration of α-$C_5H_4NNMe_2$), a *compd.*, apparently **XXIV** or **XXV**, yielding on cautious treatment with alkalies or, better, with NH_3 a *base* (XXVI) with the compn. of a β'-nitro-*N*-methyl-α-pyridone methylimide, which can also be prepd. by direct nitration of *N*-methyl-α-pyridone methylimide. **XXVI** dissolves in alkalies (but not in NH_4OH) with intense orange color; the solid **XXVI** itself and its aq. solns. are also intensely yellow, properties best explained by the tautomeric *p*-quinoid structure **XXVII**. Boiling H_2O decomps. **XXVI** in 2 ways: chiefly into the original **XI** and MeOH and to a lesser extent into β'-nitro-*N*-methyl-α-pyridone and $MeNH_2$. *β-Nitro-α-methylaminopyridine* (XII) (14 g. from 15 g. **X** and MeI at 120°), golden yellow, m. 63–4°, b_{740} 262–2.5°, easily volatile as such and with steam and Et_2O vapors, forms deeply colored aq. solns. which stain the skin, sol. without color in dil. mineral acids, the solns. becoming yellow on diln., has a strong odor somewhat resembling that of CHI_3. *α-[Methylnitramino]pyridine* (13.4 g. from 10.8 g. α-C_5H_4NNHMe in cold H_2SO_4 with HNO_3), m. 30–1°, insol. in alkalies, easily sol. in dil. mineral acids. *β'-Nitro-α-[nitrosomethylamino]pyridine* (XIV) (4 g. from 3.85 g. **XI** with $NaNO_2$ in cold 10% H_2SO_4), faintly yellowish, m. 112–3°, insol. in dil. mineral



(XXIV)



(XXV)



(XXVII)

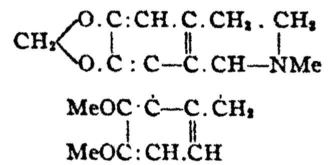
β-Nitro isomer (XV) (2.5 g. from 3.85 g. **XII**), yellow, m. 102–3°. *β-Bromo-β'-nitro-α-methylaminopyridine* (XVI) (1.1 g. from 1.65 g. **XI** in 10% H_2SO_4 with Br-NaBr), yellowish green, m. 163–4°, insol. in dil. mineral acids. *β',β-Isomer* (XVII) (1.4 g. from 1.54 g. **XII**), intensely yellow, m. 149–50°. *β-Nitro-α-[methylnitramino]-pyridine* (XXI) (1.1 g. from 1.5 g. **XII** and HNO_3 in cold H_2SO_4), light yellow, m. turbid, clear 105°, insol. in alkalies and dil. mineral acids. *β,β'-Dinitro-α-methylaminopyridine* (XX) (0.25 g. from 0.35 g. **XXI** in H_2SO_4 at room temp.), yellow, m. 147–8°, insol. in alkalies and dil. mineral acids. **XXIV** (19.8 g. from 15 g. **XI** and MeI at 125°),

m. 225° (decompn.). **XXVI** (4 2 g. from 9 g. **XXIV** with NH_4OH), light yellow, m. 149.5–50.5°. *β'-Nitro-α-[methylacetamido]pyridine* (3 g. from 3 g. **XI** and Ac_2O on the H_2O bath), m. 99°, insol. in cold dil. acids and alkalies but completely sapond. by boiling 0.5 min. with 0.5% HCl or NaOH; **XII** is not acetylated under the same conditions. C. A. R.

Some reactions of bromo derivatives of α-aminopyridine. A. E. Chichibabin and A. V. Kirsanov. *Ber.* **61B**, 1236–44(1928); cf. preceding abstr.—The object of this work was to det. whether in the methylation of halogen derivs. of α-$C_5H_4NNH_2$ (I) and subsequent nitration the same anomalies occur as had been found in the NO_2 derivs. of I. On heating α,β,β'-$C_5H_2N(NH_2)Br_2$ (II) with MeI, the reaction follows the same course as with I itself *β,β-dibromo-N-methyl-α-pyridone imide* (III) being the chief product and only a small quantity of α,β,β'-$C_5H_2N(NHMe)Br_2$ (IV) being formed. IV was identified by its prepn. from the Na deriv. of II with Me_2SO_4 and from α-C_5H_4NNHMe (V) with Br, α,β'-$C_5H_3N(NHMe)Br$ (VI) being obtained as an intermediate product in the latter reaction. With HNO_2 IV yields a stable NO deriv. while III gives *β,β'-dibromo-N-methyl-α-pyridone* (VII). On nitration in cold concd. H_2SO_4, II, III and IV yield mono-NO_2 derivs., VIII, IX and X, resp., with the NO_2 group on the amino (or imido) N atom. VIII in aq alkalies with Me_2SO_4 gives IX, which, like *N*-methyl-α-pyridone nitrimide and its NO_2 derivs., evolves N_2O with hot alkalies and forms VII. In the nitration of II in H_2SO_4 *there is a partial replacement of the β'-Br atom by* NO_2, with formation of α,β',β-$C_5H_2N(NH_2)(NO_2)Br$ (XI), as had already been observed. With the preformed nitramino derivs no such replacement of the Br atom has been noted, but there is a partial removal of the NO_2 group from the amino N atom with regeneration of the original II or IV. The HNO_2 resulting from the reduction of the HNO_3 also gives in the cold some of the NO deriv. of IV. Furthermore, the $NHNO_2$ or $NMeNO_2$ group is partially replaced by OH with formation of α,β,β'-$C_5H_2N(OH)Br_2$ (XII). When IX is heated with concd. H_2SO_4 the Me group does not migrate but either the NO_2 group is split off with regeneration of III or the $=NNO_2$ group is replaced by O, with formation of VII. Provisionally, it may be assumed that migration of the Me group is caused by the entrance of the NO_2 group into the C_5H_5N nucleus or by NO_2 groups already present. The reactions of derivs. of II with H_2SO_4 are not smooth, however; the odor of Br can always be detected, the product becomes dark and large quantities of non-crystallizable substances are formed. *HI salt* of III (35 g. from 25.2 g II and MeI on the H_2O bath in a sealed tube), greenish needles with 0.5 H_2O, begins to darken 200°, m. 218 9° (decompn.). Free III, best prepd. by decompg. the HI salt with NH_4OH and extg. repeatedly with C_6H_6, light yellow, m. 99–100°, cannot be extd. from AcOH with Et_2O, melts under hot H_2O, dissolves readily in dil. acids, is very sensitive to the peroxides present in old Et_2O. *β,β'-Dibromo-α-methylaminopyridine* (IV) (yield, 0.4 g. in the above prepn. of III. HI, 2 g. from 11.2 g. II with $NaNH_2$ in Et_2O and Me_2SO_4, or 3.5 g from 2.6 g. V and 10.7 cc. of a soln. of 10 cc Br in 50 cc. KBr), m. 56.5–7°, b_8 137–8°, is volatile with steam and has a peculiar pleasant smell. *β'-Bromo-α-methylaminopyridine* (VI) (1 g. from 2 6 g. V with 5 35 cc. Br-KBr (10 cc. Br in 50 cc. KBr)), m. 70–1°, sol. in dil. mineral acids. *NO deriv.* of IV (1 g. from 1.33 g. IV in 4% H_2SO_4 at 0° with $NaNO_2$), m. 56–7°, smells faintly of nitrosamines, insol in alkalies or dil. acids. *β,β'-Dibromo-α-nitraminopyridine* (VIII) (7.7 g. from 12 6 g. II), yellow, darkens 121°, m. 123° (decompn.), easily sol. in alkalies, NH_4OH and alkali carbonates. *β,β'-Dibromo-N-methyl-α-pyridone nitrimide* (IX) (4 7 g. from 4.7 g III), darkens about 180°, m 186–7° (decompn.), insol. in dil mineral acids and in alkalies, very unstable toward hot alkalies, giving N_2O and VII, m. 182°, insol. in alkalies or dil. mineral acids. C. A. R.

Alkaloids of Corydalis cava. XII. Synthesis of *d*-bulbocapnine methyl ether. Ernst Späth and Otto Hromatka. Univ. Wien. *Ber.* **61B**, 1334–42(1928); cf. *C. A.* **22**, 1781.—The structure of bulbocapnine (I) had been established except for the positions of the HO and MeO groups and this gap has now been filled in by the synthesis of *d*-bulbocapnine Me ether (II). The most promising way to the synthesis of all aporphine derivs. seemed to be the conversion of 1-[*o*-nitrobenzyl]isoquinoline derivs. (III) through the methochloride into derivs. of 1-[*o*-aminobenzyl]-*N*-methyltetrahydroisoquinoline, diazotization of the latter and transformation with Cu powder by the Pschorr method into phenanthrenes of the desired structure. The prepn. of the III often presents great difficulties. It has proved relatively easy, to be sure, in 2 cases (papaverine, 1-veratrylhydrohydrastinine) where direct nitration of compds. already contg. the isoquinoline ring has introduced the NO_2 group into the 2-position, but with other III treatment with HNO_3 results either in nitration at an undesired position or in the formation of an inseparable mixt. of isomers. In spite of Pictet

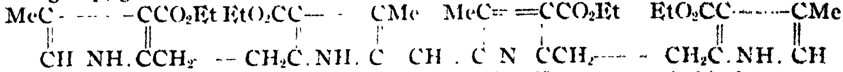
and Kay's inability to synthesize apomorphine by Bischler and Napieralski's method, starting from an acid amide already contg. a NO_2 group, S. and H. prepd., for the synthesis of II, *[2-nitrohomoveratroyl]homopiperonylamide* (IV), from 2,3,4-$O_2N(MeO)_2$-$C_6H_2CH_2COCl$ (V) (made from the acid and $SOCl_2$) and homopiperonylamine in C_6H_6 with NaOH. The IV, treated with P_2O_5 60–70 min. (not 5-15 min as is usual) gave almost 34% of the *dihydroisoquinoline deriv* (VI). One of the essentials for the success of the reaction seems to be the use of a relatively small quantity of substance and of a large quantity of solvent (in a trial expt. with 0.1 g. IV in 20 cc. PhMe the yield was 60%). VI MeCl with Sn and alc. HCl gives 66% of the oily *amino-N-methyltetrahydroisoquinoline deriv.* (VII), converted by diazotization and subsequent treatment with Cu powder and reduction with Zn dust and concd. HCl into II. Bases of the type of dilaudanosine, phenol bases and other impurities are of course also formed. The purification of the II presented great difficulties but was effected by fractional distn. in a high vacuum. Resolution of the product with *l*-tartaric acid yielded a product identical in m. p., rotation and MeO content with natural II, thus establishing its structure as being



V, m. 54–6°. IV (yield, 94.6%), m. 158° (all m. ps. in evacuated tubes). VI, m. 167.5–8.0°, sol. in cold dil. HCl and repptd. by alkalies; *HCl salt*, m. 217–8° (blackening); *methiodide*, light yellow, m. 192 3° (decompn.); *methochloride*, light yellow lacquer. II, m. 128–9°, $[\alpha]_D^{20}$ 259.5° ($CHCl_3$). *dl*-II, prepd. by methylating natural I with CH_2N_2 and racemizing the resulting *d*-II essentially according to Gadamer and Kuntze, m. 135.5–6 0°; *picrate*, m. 213–4° (decompn.). C. A. R.

Determination of the active hydrogen in hemin, some derivatives and pyrrolenes. III. H. Fischer and Paul Rothemund. Techn Hochschule München. *Ber.* **61B**, 1268–76(1928); cf. *C. A.* **22**, 1784.—In the 1st paper F. and Postowsky reported active H detns., by the Zerevitinov method, on a series of simple pyrrolenes, dipyrrylmethenes, hemin and bile pigment derivs. The results with hemin were consistent but the drawing of definite conclusions concerning the other substances was postponed until it should have become possible to use larger quantities for the detns. Shortly afterward, Kuhn, Braun, Seyffert and Furter (*C. A.* **21**, 2702) described a dihydrohemin, obtained by catalytic hydrogenation of hemin, characterized by the presence of 5 active H atoms, whereas in hemin they found, in agreement with F. and P., only 3. In the meantime, F. had obtained varying values (3–5 active H atoms) for hemin, and as considerable doubt has been cast, recently, on the general applicability of the Z. method, F. and R. have again taken up a study of it, considering all possible sources of error, especially the blanks. Z. recommends that detns. be made only when the blank is negative, and claims that by proper preliminary treatment of the C_5H_5N the blank can be brought down to zero, but even then a single opening of the vessel often results in a great increase in the blank, so that the requirement of a negative blank is not practicable. In their present work, F. and R made no detns. with the blank exceeding 4. Under these conditions the high values for hemin reported in the 2nd paper were not obtained, the values obtained in 7 expts. being 2.08–3.46; some of the prepns. used in the earlier work now gave abnormally low results (1.38–2.26), so that long standing of the substances may have some effect on the results. Furthermore, the values are comparable only when in the analyses the time intervals are kept the same within very narrow limits and when in reading the gas vol. Z.'s directions are followed exactly, *i. e.*, the minimum gas formation is taken as the basis for the calcn. Although working under N does not overcome these difficulties, all the detns. were made in N. Complete soln. of the substance is important; hemin without C_5H_5N gives no gas. The formation of a ppt. when the Grignard soln. is added may be another source of error; the quantity of gas evolved often depends on the way the mixt. is shaken. In all cases the mixts. were shaken vigorously for 1 min. but with the porphyrins the reaction was certainly not yet complete for the porphyrin spectrum could still be detected regularly along with the phyllin spectrum. Bis-[2,4-dimethyl-3-carbethoxypyrryl]methene gave 1–1.5 active H atoms, its HBr salt 2.6–2.97 (theoretical, 2). [2-Bromo-3-carbethoxy-4-methylpyrryl]-[2',4'-dimethyl-3'-carbethoxypyrryl]methene also gave a high value (1.49;

calcd., 1). The aldazine of 2,4-dicarbethoxy-3-methyl-5-formylpyrrole and its Cu complex gave about the same values (2.07–2.43, 2.53–3.01, resp.), although theoretically the former contains 2, the latter 0–1 active H atoms. These results indicate that besides the NH groups in the pyrrole derivs. the methine groups also react with the Grignard reagent. If this is true the Z. method appears fundamentally unreliable for porphyrins and hemins, which contain 4 methine groups. [2-Methyl-3-carbethoxy-4-hydroxypyrryl][2′,4′-dimethyl-3′-carbethoxypyrryl]methene, with two NH and one CH group, gave 2.06 active H atoms. The more complicated methene



with three NH and one CH group, gave only 2.6 active H atoms, probably because a good part of the substance crystd. out. Hemin di-Me ester gave 0.96, tetramethylhematoporphyrin-Fe salt 0.89 active H atom. Widely varying results were obtained for uroporphyrin ester (2.07–7.79), isouroporphyrin ester (4.02–6.31), octaethylporphin (1.32) and acetonepyrrole (2.76–3.76). Etioxanthoporphinogen gave 4.50, its mono-K salt 4.39–4.53, di-K salt 3.76–3.90, octaethylxanthoporphinogen 4.23, tetramethyltetrapropylxanthoporphinogen (I) (dried at 50° and contg. $2H_2O$) 9.69, tetra-Me coproporphyrinxanthoporphinogen 6.75. No exptl. evidence could be obtained that the H_2O content is responsible for the abnormally high value given by **I**; in PhN:NPh to which had been added a little H_2O the active H found was not materially greater than that corresponding to the added H_2O. F. and R. conclude that unavoidable catalysts greatly influence the gas evolution in the Z method and complex pyrrole derivs. can of themselves exert such influences; moreover, the methine groups in them also react. The cautious position adopted in the 1st paper as to the interpretation of the results of the Z. method when applied to hemin was and remains entirely justified.

Hydrocarbon. Alwin Mittasch, Walter Frankenberger and Fritz Winkler (to I. G. Farbenind. A.-G.). Can. 283,411, Sept 18, 1928. Liquid hydrocarbons of low boiling point are produced by acting on gases comprising olefins in the presence of CH_4 at 200–900° and under elevated pressure with at least one of the following catalysts: noble metal, Cu, alkali metal compds., oxygen acids of P, B, Sb and metal salts thereof, in particular alkali metal salts.

Hydrocarbons. Wilhelm Gessmann and Eduardo W. Shalders. Can. 282,392, Aug. 14, 1928. Easily boiling hydrocarbons are produced by passing a mixt. of unsatd. hydrocarbons and a gas contg. carbon oxide and H without applying heat and at normal pressure over a catalyzer subjected to chemically active light rays. The catalyst consists of a mixt. of pure powd. electrolytic Cu, W and pumice stone powder treated with a dil. caustic alk. lye and quickly dried.

Oxygenated organic compounds from oxides of carbon by reduction. I. G. Farbenind. A.-G. Ger. 462,837, June 28, 1928. In the catalytic prepn. of oxygenated org. compds., *e. g.*, methanol, by reduction of oxides of carbon by H or hydrocarbons or both at high temps. and pressures, the mixt. of gases entering the reaction is completely freed from catalyst poisons, not only sulfur compds. especially org. ones but also from volatile iron compds., preferably by using active carbon.

Organic arsenic compounds. August Albert. Ger. 463,313, July 5, 1928.

Addn. to Ger. 459,649. Arsenic compds. contg. a CO group, not in a ring, are condensed with compds. contg. several hydrazine groups. In examples *p*-acetophenonearsonic acid or 1-acetophenone-3-hydroxy-4-arsenobenzene is condensed with carbohydrazide, malonyl hydrazide, oxalyl hydrazide, thiocarbohydrazide, triaminoguanidine dinitrate or diaminoguanidine dihydrobromide.

Arsenic compounds. LEOPOLD CASSELLA & Co. Ger. 452,065, Nov. 5, 1927. 4-Hydroxy-3-amino-1-phenylarsinoxide (400 g.) is mixed with 4 l. of H_2O and 400 cc. of 10 *N* NaOH and 250 cc. Ac_2O is added. The acetyl product is filtered off by suction. It can be recrystd. from a NaOAc soln. The product is sol. in hot water and cold caustic alkalies and alkali carbonates, difficultly sol. in cold weak mineral acids, and easily sol. in alc. and weak AcOH. Ten g. 4-hydroxy-3-aminophenyl-1-arsonic acid is dissolved in 200 cc. 10 *N* HCl and 40 cc. H_2O and mixed with 2 g. KI dissolved in 20 cc. of H_2O. SO_2 is bubbled through the soln. for several hrs. and the ppt. filtered off and dissolved in 60 cc. of H_2O. The soln. is cooled, neutralized with NH_3 and satd. with NaCl. The arsinoxide is filtered off and washed with salt water. It is then brought into soln. with 150 cc. H_2O and 25 cc. 10 *N* NaOH and shaken well with 5 cc. BzCl while being warmed on a water bath. Ten cc. BzCl is further added in 2 portions and warmed a short time. The crude product ppts. It is redissolved in 0.5 *N* NaOH, filtered and pptd. by addition of HCl. The resulting product is almost insol. in H_2O, and sol. in hot soda soln., cold NaOH, alc. and boiling AcOH. It is not diazotizable. Fifteen g 3-hydroxy-4-aminophenyl-1-arsonic acid is dissolved in 60 cc. H_2O and 300 cc. 10 *N* HCl and mixed with 3 g. KI in 30 cc. H_2O. A thick paste results, through which SO_2 is bubbled for several hrs. The resulting ppt. is filtered off, dissolved in 75 cc. H_2O, filtered through animal charcoal and pptd. with strong HCl in excess The ppt. is filtered off, levigated with 100 cc. H_2O and dissolved with 50 cc. NaOH (40° Bé.). The soln is treated with BzCl and finished in the same manner as in the second example.

Arseno compounds. AUGUST ALBERT. Ger. 463,577, July 12, 1928. Condensation products from mixed aliphatic-aromatic carbonyl arsenic compds. with amino compds. (except $(NH_2)_2$ and its derivs.) are reduced in H_2O soln. or suspension with $Na_2S_2O_4$. Examples: *p*-Acetophenonearsonic acid and *p*-aminoacetophenone, arseno compd. unchanged at 270°; *p*-acetophenonearsonic acid and anthranilic acid, arseno compd. unchanged at 270°; *p*-aminoacetophenonearsonic acid and urea, arseno compd. unchanged at 280°; *p*-benzaldehydearsonic acid and aminoantipyrine, arseno compd. decomps. about 200°; 1-hydroxy-2-acetophenone-4-arsonic acid and *p*-phenetidine, arseno compd., sinters and darkens 220°; *p*-acetophenonearsonic acid and *o*-aminobenzaldehyde, arseno compd. decomps. 225°; *p*-acetophenonearsonic acid and glycocoll, arseno compd. darkens about 250° without melting; *m*-nitrobenzaldehydearsonic acid and benzylhydroxylamine-HCl, arseno compd. decomp. 120°; *p*-benzaldehydearsinoxide and NH_2OH-HCl, arseno compd. infusible at 280°. The C=N bond is not reduced in these compds.

Preparation of organic phosphorus compounds. LEOPOLD CASSELLA & Co. Ger. 452,064, Nov. 5, 1927. Tetrahydronaphthalene 100 parts is mixed with 100 parts PCl_3 and 100 parts of $AlCl_3$ is carefully introduced. After the reaction is completed the reaction mixt. is heated for 3 hrs. on a water bath. The thick oily mass is introduced into ice water, the ppt. filtered off, taken up in weak soda or NH_3 soln. and again pptd. with HCl. The resulting product is insol. in H_2O and weak mineral acids, easily sol. in alkalies or alkali carbonates, MeOH, EtOH, acetone, C_6H_6, and warm $CHCl_3$ and difficultly sol. in ether. A similar process can be carried out by reaction of 100 parts of decahydronaphthalene, 160 parts PCl_3 and 100 parts $AlCl_3$ or 50 parts tetrahydronaphthalene, 35 parts PCl_3 and 10 parts $AlCl_3$ and warming the latter for 40 hrs. on the water bath.

Halogenated organic compounds. I. G. FARBENIND. A.-G. Brit. 283,877, Jan. 18, 1927. The mixt. of products obtained in the halogenation of org. compds. (such as the mixt. of methyl, methylene and H chlorides obtained by passing MeCl and Cl through a chamber heated to 360–380°) is treated with an alc. such as MeOH under conditions to effect a reaction between the alc. and the H halide present. Heating, increased pressure or catalysts may be used to facilitate the reaction.

Chlorides of aromatic *o*-hydroxycarboxylic acids. ERIC B. HIGGINS (one-half to British Synthetics, Ltd.). U. S. 1,684,273, Sept. 11. Chlorides of aromatic *o*-hydroxycarboxylic acids are produced by causing thionyl chloride to react (preferably in theoretical proportions) upon a salt of the acid in question such as the mono-Na salt of 2,3-hydroxynaphthoic acid (suitably by grinding the reagents together in a ball mill).

Chlorides of aromatic oxamic acids. I. G. FARBENIND. A.-G. (Josef Haller,

inventor). Ger. 463,140, July 5, 1928. Hydrochlorides of aromatic primary amines, *e. g.*, $PhNH_2.HCl$, α- and β-$C_{10}H_7NH_2.HCl$, or *o*-$MeC_6H_4NH_2.HCl$, are stirred at ordinary temp. with *oxalyl chloride* to obtain phenyloxamyl chloride, m. 82.5°, almost theoretical yield, α-naphthyloxamyl chloride, yellowish needles, m. 86°, β-naphthyloxamyl chloride, colorless needles from C_6H_6, m. 114–5° (decompn.), or *o*-tolyloxamyl chloride, yellow needles, m. 89–90°.

Decomposing cyclic compounds with hydrogen and catalysts. I. G. FARBENIND. A.-G. Brit. 283,600, July 12, 1926. A mixt. of carbazole vapor with H is passed at 350° over a catalyst prepd. by reducing in H at 400° a mixt. of $Al(OH)_3$ and Fe oxide; the products include C_6H_6, NH_3 and $PhNH_2$. Other catalysts for use in this reaction may be prepd. similarly from mixts. of (*a*) oxides of Zn, Cr, Cu and Fe; (*b*) oxides of Mg and Fe; (*c*) oxides of Zn, Fe and Al; or, (*d*) oxides of Zn, Fe and Ti. Cresol vapor with H is passed at 450° over a catalyst prepd. by reducing in H at 350° a mixt. of oxide of Fe and Al; the products include C_6H_6 and toluene. Other phenols or phenolic mixts. such as tar fractions may be similarly treated, preferably by using mixed catalysts contg. a component having both dehydrogenating and dehydrating properties such as Fe_2O_3 or oxides of Mo or U. A light oil is obtained from low-temp. tar by passing a mixt. of its vapor with H at 450° over a catalyst prepd. by reducing in H at 350° a mixt. of Fe oxide, MgO and NH_4 vanadate. Centrifuged crude $C_{10}H_8$ vapor with H is passed at 450° over a catalyst prepd. by reducing in H at 400° a mixt. of Fe oxide and NH_4 molybdate; the product comprises C_6H_6 and other liquid hydrocarbons, and, by varying the conditions, there may be obtained chiefly toluene, *o*-xylene and other homologs of C_6H_6. Numerous other details and modifications of processes for effecting similar reactions are described.

Preparation of carbocyclic and heterocyclic compounds. I. G. FARBENIND. A.-G. (Erwin Hoffa, inventor). Ger. 464,087, July 26, 1928 FSO_3H (I) is used instead of $ClSO_3H$, or $H_2S_2O_7$ in ring closing. In some cases, *e. g.*, in the prepn. of thioindigo dyes the oxidizing action of I is used to oxidize the hydroxythionaphthenes, resulting primarily from the arylthioglycolic acids, to thioindigos. In examples *m*-chlorophenylthioglycolic acid with I gives chlorohydroxythionaphthene; 1-chloronaphthalene-2-thioglycolic acid (II) gives at 15–20° the corresponding hydroxythionaphthene. This can be oxidized to the corresponding thioindigo or condensed with isatin and its derivs. to indirubin dyes. Ring closure and oxidation of II with I gives a blue, reddish tinged, dye of good fastness. 4-Aminoanthraquinone-1-anthranilic acid is similarly converted to 4-aminoanthraquinone-1,2-acridone, *o*-benzoylbenzoic acid to anthraquinone, α-naphthoylbenzoic acid to benzanthraquinone and *o*-methylhydrocinnamic acid to 4-methyl-1-keto-2,3-dihydroindene.

Unilaterally acylated diamines. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Ger. 464,142, July 26, 1928. Alkylenediamines, of which one N is a tertiary amino N, are made to react with acid halides or anhydrides of higher fatty acids. Alkylenediamines are made to react with higher fatty acids or their esters, using more than one mol. of amine per mol. of fatty acid. In examples linoleic acid is caused to react with asymm diethylenediamine; stearic acid with ethylenediamine hydrate (I) gives distearylethylenediamine, basic smelling crystals from AcMe, m. 103°, and monostearylethylenediamine, sol. in H_2O to a turbid, alk. liquid. Mono- and dioleylethylenediamine from oleic acid (II) and I. Propylenediamine and olive oil give a mixt. of stearyl-, palmityl- and oleylethylenediamines. ω-Amino-*N*-ethylpiperidine and II give oleylpiperidyl-*N*-ethylamine. Asymm. dimethylethylenediamine and stearyl chloride in C_6H_6 give stearyldimethylethylenediamine, insol. in H_2O, sol in org. solvents, crystals from H_2O + AcMe, m. 71°. Asymm. diethylethylenediamine and II heated to 200–20° give oleyldiethylethylenediamine, thick oil, insol. in H_2O, sol. in org. solvents.

Diarylamines and their derivatives. HANS BUCHERER. Ger. 451,980, Nov. 1, 1927. *p*-$C_6H_4(NH_2)_2$ or its derivatives are treated with sulfurous acid esters of phenol or the α-naphthol series in the presence or absence of an excess of sulfite. A condensation product results. *E. g.*, (1) Resorcinol, *p*-$C_6H_4(NH_2)_2$, 11 g. each, and 150 cc. of 30% bisulfite soln. are heated together. Upon cooling. 3-hydroxy-4-aminodiphenylaminesulfonic acid crystallizes out. (2) 1,4-$H_2NC_{10}H_6SO_3Na$ (25 g.) is heated with 11 g. *p*-$C_6H_4(NH_2)_2$ and 150 g. of 30% bisulfite soln. Upon cooling the reaction product crystallizes out. (3) 1,4-$H_2NC_{10}H_6SO_3H$ (16 g.), heated for 24 hrs. with 10.5 g. *p*-aminodimethylanilinethiosulfonic acid and 60 g. of bisulfite soln. yields a thiazine. (4) 1,4-$H_2NC_{10}H_6SO_3H$ (16 g.) with 13 g. of 1,2,4-$H_2N(HO)C_{10}H_5SO_3H$ gives a product that is probably an oxazine. Similarly α- or β-naphthol sulfurous acid esters can be condensed with *p*-aminodimethylanilinethiosulfonic acid to form thiazines or oxazines.

Aminoguanidines or their salts. SCHERING-KAHLBAUM A.-G. Ger. 463,576,

July 12, 1928. Diamines, *e. g.*, $H_2N(CH_2)_4NH_2$ or $H_2N(CH_2)_5NH_2$, and hydrazines, *e. g.*, $(NH_2)_2$ or CH_3NHNH_2 or their hydrates give aminoguanidines or their salts on the addition of alkylisothiourea salts, *e. g.*, methyl- or ethylisothiourea sulfate. The reaction takes place with all diamines, hydrazines and their alkyl derivs.

Double compounds of sulfur dioxide with aldehydes or ketones. RUDOLF BAYER CHEMISCHE FABRIK. Ger. 464,010, July 26, 1928. SO_2 in liquid or solid state is caused to react with aldehydes or ketones or liquid SO_2 (I) is allowed to run into the liquid aldehydes or ketones. In examples the double compds. are obtained from I and acetone, benzaldehyde and a mixt. of acetone oil and tolualdehyde.

Sulfonated compounds. CHEMISCHE FABRIK MILCH A.-G. (to Oranienburger chemische Fabrik A.-G.). Brit. 283,864, Jan. 17, 1927. Acids of low mol. wt. such as acetic, propionic, butyric or lactic acid are condensed with aromatic or hydroaromatic hydrocarbons or their derivs. by use of dehydrating and strongly sulfonating substances such as halosulfonic acids, to produce sulfo acids. Polynuclear compds. such as $C_{10}H_8$, $C_{14}H_{10}$ and their derivs. formed by alkylation, chlorination, hydroxylation or hydrogenation are suitable for the aromatic components. The products may be used as emulsifying agents for solvents which are insol. in water or difficultly sol. and for mineral oils and fatty substances, and may be used alone or in various mixts. as pasting, cleaning, lathering, wetting or fatting agents in the color, paper, textile and leather industries and in laundry, dyeing, bleaching, carbonization, mercerizing and finishing operations and as prewetting and cleaning agents for sensitive wools, silks and feathers. Several examples are given.

Lower aliphatic acids. BRITISH CELANESE, LTD., H. DREYFUS AND C. I. HANEY. Brit. 283,702, Nov. 30, 1926. Acetic, propionic and other lower aliphatic acids are extd. from aq. solns. by a mixt. of a solvent for the acid (such as ether, $CHCl_3$ or acetone oil) and a hydrocarbon such as C_6H_6 or gasoline. Numerous details of procedure are given.

Dinaphthyldicarboxylic acids. RICHARD HERZ and WERNER ZERWECK (to Grasselli Dyestuff Corp.). U. S. 1,684,272, Sept. 11. In making 1,1'-dinaphthyl-8,8'-dicarboxylic acid or other dinaphthyldicarboxylic acid of the general formula $(C_{10}X_6)_2$-$(COOH)_2$, in which X stands for H atoms one or more of which may be replaced by a univalent substituent, 1,8-aminonaphthoic acid or other suitable aminonaphthoic acid compd. is diazotized and the diazo compd. is treated with an ammoniacal soln. of Cu_2O, and the dinaphthyldicarboxylic acid produced is isolated by acidifying the soln. formed. Several examples are given.

Sulfonic acids. G. S. PETROV. Russ. 508, Sept. 15, 1924. Sulfonic acids obtained according to pat. 428 are taken up with water and EtOH. MeOH or AcMe is added to the aq. layer to sep. the hydrocarbons present.

Anhydrous salts of lower fatty acids. HOLZVERKOHLUNGS-INDUSTRIE A.-G. Ger. 463,829, July 19, 1928. Anhydrous esters, *e. g.*, methyl acetate, are treated with anhydrous hydroxides, *e. g.*, NaOH in solvents, *e. g.*, alcohols.

Bile acid salts of cephaeline alkyl ethers. CHEMISCHE FABRIK VORM. SANDOZ. Brit. 283,533, Jan. 12, 1927. Bile acid salts of cephaeline alkyl ethers are prepd. by combining the alkaloids with the bile acids in mol. proportions or by double decompn. of suitable salts of the bases and acids. Examples are given of the combination of emetine with cholic or desoxycholic acid and of cephaeline ethyl ether with cholic acid. Other bile acids also may be used.

Esters of glycolic acid. DR. ALEXANDER WACKER GES. FÜR ELEKTROCHEM. IND. G. m. b. H. Ger. 463,139, July 5, 1928. Alkali chloroacetates are heated in the presence of a small amount of water or other liquid of suitable b. p. and the resulting glycolic acid is esterified with alc. and mineral acid. In an example chloroacetic acid (I) is neutralized with Na_2CO_3 (II) and heated under reflux below 150°. The resulting mass is esterified with BuOH and H_2SO_4. In another example, I, II and BuOH are heated 2 hrs. at 140°, then esterified by using H_2SO_4. Ethyl glycolate can be made similarly. The esters are useful as *plasticizers* for *lacquers*.

Anthraquinone derivative. I. G. FARBENIND. A.-G. Ger. 451,907, Nov. 1, 1927. One part benzylideneanthrone is introduced into a mixt. of 1 part of NaCl and 4 parts of $AlCl_3$ at 100–110°. The mixt. is heated for a short time and boiled with dil. HCl. A resin forms which can be crystd. from pyridine. One part benzylideneanthrone and 1 part anhydrous $AlCl_3$ are heated to 120–150° until the benzylideneanthrone is completely used up. The inorg. portion of the mixt. is washed out with HCl and the reaction product recrystallized from pyridine. $SbCl_5$ can be substituted for $AlCl_3$.

Pyridine derivatives. SCHERING-KAHLBAUM A.-G. (FORMERLY CHEMISCHE FABRIK AUF ACTIEN, VORM. E. SCHERING). Brit. 283,576, Jan. 14, 1927. 2-Amino-5-iodopyri-

dines are made by reaction of alkali on the chloroiodo compds. of 2-aminopyridines obtainable as described in Brit. 264,508 (*C. A.* **22**, 91). Examples are given for the production of 5-iodo-2-amino-, 5-iodo-2-ethylamino-, 5-iodo-2-isopropylamino-, 5-iodo-2-isoamylamino- and 5-iodo-2-diethylaminopyridine and 5-iodo-2-amino-6-methyl-3-ethylpyridine by the action of an excess of NaOH soln. on the corresponding chloroiodo compds.

Quinoline derivatives. SCHERING-KAHLBAUM A.-G. (FORMERLY CHEMISCHE FABRIK AUF ACTIEN, VORM. E. SCHERING) Brit. 283,577, Jan. 14, 1927. 4-Alkylquinolines are made by condensing aniline or its derivs. with alkyl β-haloethyl ketones (which may be obtained as described in Brit. 282,412 (*C. A.* **22**, 3668)) in acid, neutral or alk. soln. and with or without use of an oxidizing agent such as $PhNO_2$ or arsenic acid. 4-Methylquinoline (lepidine) is made from aniline and methyl β-chloroethyl ketone; 6-methoxylepidine from *p*-anisidine; 8-methoxylepidine from *o*-anisidine; 6-ethoxylepidine from *p*-phenetidine; 6-nitrolepidine from *p*-nitroaniline; lepidine-8-carboxylic acid from anthranilic acid ester (sapon. is effected during the condensation); and 4-ethylquinoline from aniline and ethyl β-chloroethyl ketone; condensation may be effected in the presence of $PhNO_2$ and concd. HCl or 40% H_2SO_4, or, in one instance, in the presence of NaOH. Usually a mixt. of bases is first produced and the desired product is isolated as the picrate except with the carboxylic acid.

Prevention of polymerization of vinyl compounds. KENNETH G. BLAIKIE (to The Canadian Electro Products Co., Ltd.). Can. 282,860, Aug. 28, 1928. Polymerization of vinyl compds. and their reaction with aldehydes in mixts. of same is prevented by adding S to the vinyl compds.

Guanidino alcohols. SCHERING-KAHLBAUM AKT.-GES. (Herbert Schotte, inventor). Ger. 462,995, June 28, 1928. Cf. Ger. 455,682 and Erlenmeyer, *Ber.* **14**, 868(1881). Salts of amino alcs. react with cyanamide in EtOH soln. at 100–110° in autoclaves to give guanidino alcohols. In examples methylaminoethanol-HBr gives methylguanidinoethanol-HBr, m. 101–3°, picrate m. 166°. Free base sol. in H_2O, EtOH, insol. in Et_2O, AcOEt, and $CHCl_3$. Ethylaminoethanol-HCl gives ethylguanidinoethanol-HCl, picrate, m. 158°, very sol. in H_2O as are the Me and isoamyl derivs. Isoamyl deriv., sol. in H_2O and EtOH, picrate, m. 117–8°. Benzyl deriv., sol. in H_2O and EtOH, picrate oily. *o*-Acetylmethylaminoethanol-HCl (from chlorohydrin acetate and methylamine) gives *o*-acetylmethylguanidinoethanol-HCl, sol. in OH-contg. solvents, insol. in Et_2O and $CHCl_3$. Aminoethanol sulfate gives guanylcholamine sulfate, hygroscopic crystals, hydrobromide, hygroscopic, picrate, difficultly sol. in H_2O, picrolonate, very difficultly sol.

Benzanthrones. BRITISH ALIZARINE CO., LTD., W. H. DAWSON, C. W. SOUTAR AND J. ANDERSON. Brit. 284,035, Nov. 3, 1926. Anthraquinones or the corresponding anthranols are condensed with the reaction mixt. obtained by treating glycerol with a S-contg. chlorinating agent such as S_2Cl_2 or SCl_2, thionyl chloride or sulfuryl chloride. Some of the products contain S and yield compds. of the violanthrone type by fusion with alc. KOH. Several examples are given.

Chlorinated ethylenes. ALEXANDER WACKER GES. FÜR ELEKTROCHEM. IND. G. m. b. H. (Walter Körner and Alfred Suchy, inventors). Ger. 464,320, Aug. 2, 1928. Cf. Ger. 222,622, 263,457 and 274,782. Chlorinated ethylenes are obtained from chlorinated ethanes, *e. g.*, trichloroethylene (I) from tetrachloroethane and perchloroethylene from pentachloroethane, by passage over strongly heated, strongly adsorbent carbon, preferably bone charcoal. Better yields (95% boiling below 100°) of I are obtained with adsorbent C at 300–310° than with $BaCl_2$ on pumice at 380–400° (70% below 100°) or at 300° (even lower yield) or with ThO_2 at 360–390° (68%). Non-adsorbent C is not active. Cf. Nicodemus (*C. A.* **5**, 2814).

Erythrene. B. V. BUIZOV. Russ. 1102, Sept. 15, 1928. The products of a pyrogenous decompn. or distn. of crude mineral oil (vapors, etc.), free from tars and liquids are subjected to the action of a red-hot wire of Pt or a similar metal.

Erythrene. B. V. BUIZOV. Russ. 1101, Sept. 15, 1924. A mixt. of C_2H_4 or EtOH with $(CH_2OH)_2$ or its halogen esters is subjected to the action of compds. or mixts which cause a catalytic splitting off of water or hydrogen halides.

Formamide. I. G. FARBENINDUSTRIE A.-G. (Rudolf Wietzel, inventor). Ger. 463,843, July 19, 1928. Addition to 460,613. Formamide is obtained by reaction of NH_3 with alkyl formates, *e. g.*, methyl formate for a short time in the presence of a catalyst, *e. g.*, Al_2O_3 at 150–200°. Cf. *C. A.* **22**, 1367.

Nitriles. I. G. FARBENIND. A.-G. (Otto Nicodemus, inventor). Ger. 463,123, July 5, 1928. Nitriles, *e. g.*, acetonitrile or diethylacetonitrile, are prepd. by passing the vapors of alcohols, monohydric or polyhydric, primary, sec. or tert., with HCN

over highly porous catalysts, *e. g.*, active C, silica gel, Al_2O_3, or ThO_2. Cf. *C. A.* 21, 2478.

Thioureas. SILESIA VEREIN CHEM. FABRIKEN (Walter Flemming and Hans Klein, inventors). Ger. 464,319, Aug. 2, 1928. Cf. Rathke, *Ber.* **12**, 774. Thioureas are prepd. from mustard oils and diarylguanidines at elevated temp. below the decompn. pt. of the thioureas, in indifferent solvents. In examples there are prepd.: *N,N'*-di-*o*-tolyl-*N"*-phenylthiocarbamidoguanidine, 93% yield, m. 179–180°, from di-*o*-tolylguanidine and phenyl mustard oil in boiling C_6H_6; *N,N'*-diphenyl-*N"*-*o*-tolylthiocarbamidoguanidine, 75% yield, m. 118–9°, from diphenylguanidine and *o*-tolyl mustard oil in boiling C_6H_6 (using xylene causes decompn.); and *N,N'*-diphenyl-*N"*-methylthiocarbamidoguanidine, 53% yield, m. 165–6°, from diphenylguanidine and methyl mustard oil.

Acetic acid. CHEMISCHE FABRIK AUF ACTIEN (VORM. E. SCHERING). Brit. 284,143, April 7, 1927. Ca acetate is added to a paste of gypsum in HOAc as obtained by reaction of H_2SO_4 on Ca acetate while avoiding an excess of H_2SO_4. After the process is initiated, the materials may be added continuously. The paste may be drawn off by an overflow to a vacuum distn. app. provided with a device for withdrawing the $CaSO_4$ which has been freed from HOAc.

Acetic acid, etc. BRITISH CELANESE, LTD., H. DREYFUS AND W. BADER. Brit. 283,989, July 20, 1926. HOAc or MeOAc is obtained by heating MeOH with CO in the presence of an inorg. acid or an inorg. acid "contg. an org. group" such as a sulfonic acid or of a corresponding acid salt The process may be carried out at atm. pressure but higher pressures which may be up to 300 atm. or more are preferred, with temps. of 300–400°. As catalysts there may be used the various phosphoric acids, boric, arsenic and phosphomolybdic acids and acid Al phosphate, either in liquid or solid state or distributed on a carrier such as coke or graphite. The process may be combined with a preliminary catalytic synthesis of MeOH and other starting materials such as Me formate may be used in effecting similar reactions instead of MeOH or MeOAc Numerous examples, modifications and details are given.

Acetic anhydride. C. RUZICKA. Brit. 283,781, May 27, 1927. Ac_2O is made by the action of SO_3 on "ordinary" or glacial HOAc. Partially converted mixts. may be used directly in *acetylating cellulose*.

Phthalamic acid. AUGUSTE CHESNAIS. Can. 282,407, Aug. 14, 1928. Phthalamic acid is prepd. by adding NH_3 water to phthalic anhydride, evapg. the excess of NH_3, washing with distd. H_2O and drying. Cf. *C. A.* **22**, 2034.

Benzobenzanthronecarboxylic acid. LEOPOLD CASSELLA & CO. Ger. 452,063, Nov. 5, 1927. Ten kg. 1,1'-dinaphthyl-8,8'-dicarboxylic acid is boiled under a reflux condenser with 200 kg. of AcOH and 20 kg. of anhyd. $ZnCl_2$ until the initial materials have gone into soln. The soln. is filtered, dild. with water and the benzobenzanthronecarboxylic acid seps. A suspension of 10 kg. of 1,1'-dinaphthyl-8,8'-dicarboxylic acid suspended in 48 kg. of 48% H_2SO_4 is treated with 230 kg. of H_2SO_4 (66° Bé.) below 60° until a test sample sepd. by water is wholly or almost wholly sol. in AcOH. The sepn. then proceeds as in the example above. The product can be purified by dissolving in alkali, filtering and pptg. with acid. Halogen or nitrogen substitution products can be made in the same manner by starting with the substituted product; *e. g.*, dibromodinaphthyldicarboxylic acid gives dibromobenzobenzanthronecarboxylic acid.

2-Phenylquinoline-4-carboxylic acid. R. VON WULFING. Brit. 283,822, Sept. 23, 1927. Isatin-bisulfite of Na or isatin and $NaHSO_3$ are dissolved in hot water, and NaOH and acetophenone are added.

Methanol synthesis. COMPAGNIE DE BETHUNE. Brit. 283,499, Jan. 11, 1927. In making MeOH by oxidizing CH_4 or from CO and H or in other exothermic reactions under pressure, water or other suitable liquid is mixed with the reaction gases and utilized to control the temp. of the reaction by the abstraction of heat for its vaporization. An app. is described.

Butyl chloride. ALEXANDER WACKER GES. FÜR ELEKTROCHEM. IND. G.m.b.H. (Georg. Basel and Felix Kaufler, inventors). Ger. 462,993, June 28, 1928; cf. *C. A.* 18, 1977. BuOH is heated in such an amount of concd. HCl that at least 10% HCl remains at the end of the reaction. The process may be continuous under pressure in Ag or Ag-plated vessels at temps. above 130° for 10–20 min.

Apparatus for subliming anthraquinone, naphthalene, camphor, etc. HERBERT G. STONE. U. S. 1,683,931, Sept. 11.

Perylene from 2,2'-dihydroxy-1,1'-dinaphthyl. COMPAGNIE NATIONALE DE MAT. COLORANTES PRODUITS CHIM. Ger. 462,894, June 28, 1928. β-Dinaphthol is heated

with $POCl_3$ and Zn dust and the resulting product distd. with or without the addn. of CaO at about 600° gives perylene. Yield 40–45%, m. 260°.

Recovering pure pyridine from pyridine base mixtures. FRITZ ARNDT and PAUL NACHTWEY. Ger. 451,956, Nov. 1, 1927. The mixt. is first concd. by fractionation and then treated with 6 *N* HCl until the basic odor disappears and then with 6 *N* $NaClO_4$ in somewhat larger quantity than the HCl. The pyridine perchlorate formed is filtered off and washed with 20% $HClO_4$ or satd. NH_4ClO_4 soln. and then dried at 110–120°. The resulting product is subjected to a stream of dry NH_3 while being cooled and decomposes into free pyridine and NH_4ClO_4. When there is still a small part of $C_5H_5NHClO_4$ left, the NH_3 stream is stopped and the mixt. heated to 100°, whereby the remaining perchlorate is decompd. The pyridine is distd. off under vacuum and freed from any water by drying over KOH.

Menthol. HANS JORDAN (to Chem. Fabrik auf Actien (vorm. E. Schering)). Can. 283,946, Sept. 4, 1928. Menthol and its isomers and homologs are produced by treating the condensation product of *m*-cresol and acetone at 180–190° in the presence of 0.1% Al 3-methyl-6-isopropylphenolate and about 1% of a Ni catalyst with H until 16 H atoms have entered into combination. Cf. *C. A.* **22**, 2952.

Recovery of pure phenol by the distillation of crude phenol. ZECHE MATHIAS STINNES. Ger. 451,958, Nov. 1, 1927. The crude phenol, preferably after a previous fractionation, is distd. with a small amount of free O or air with or without the addn. of a small quantity of an O carrier such as trinitrophenol or nitrobenzene or other carriers such as basic Zn chloride or $(BzO)_2$. The distn. is carried on under vacuum. The phenol distillate is then treated with SO_2 or H_2SO_3, washed with hot or cold water and again distd. if necessary

Lead tetraalkyl. H. W. DAUDT. Brit. 283,913, Jan. 20, 1927. Pb tetraalkyl is made in a single operation by reaction of Mg, an alkyl halide and a Pb salt, *e. g.*, a suspension of Pb chloride and Mg turnings in dry ether is treated with EtBr and the temp. gradually raised to 30–35° and later maintained at 35–39° for 12 hrs. If an alkyl chloride is used in the reaction, catalysts such as MeI and I may be required. Diluents such as gasoline, C_6H_6 or toluene may be added. Cf. *C. A.* **21**, 3907.

1,2,3,4-Tetrahydroanthraquinone. GEORG SCHROETER. Ger. 463,830, July 19, 1928. Anthracene in tetralin soln. is reduced to tetrahydroanthracene (I) with H_2 under pressure. Pure **I**, m. 103–4°, can be sepd from di- and octahydroanthracene through the picrate, m. 116°, insol. in EtOH, or by fractional distn. **I** is oxidized to 1,2,3,4-tetrahydroanthraquinone (II) by CrO_3 in HOAc soln. **II** remaining in the mother liquor is recovered by reduction to 1,2,3,4-tetrahydroanthrahydroquinone with Zn and NaOH, filtration and air oxidation.

Oxindole-3-propionic acid. CHEM. FABRIK AUF ACTIEN (VORM. E. SCHERING). Ger. 451,957, Nov 1, 1927. Mol. quantities of oxindolealdehyde and malonic acid are heated to 150–160° until the evolution of CO_2 and steam ceases. The melt is cooled and dissolved in *N* NaOH. The soln. is made acid with dil. HCl and the pptd. oxindole-3-acrylic acid filtered off. The ppt. is recrystd. several times from dil. hot alc. and boiled for some time with animal charcoal. The resulting yellowish red crystals are fairly readily sol. in alc. and AcOH, more difficulty sol. in ether and AcOEt and very slightly sol. in hot water. It decomposes at 212°. It is fairly sol. in alk. solns. and its NaOH soln. bleaches $KMnO_4$ immediately. The oxindole-3-acrylic acid is dissolved in *N* NaOH and reduced by means of an excess of Al amalgam. The oxindole-3-propionic acid obtained is recrystd. from hot water. It m. 208°, is sol. in alc., ether and glacial AcOH, less sol. in petroleum ether and hot water and nearly insol. in cold water. It crystallizes into yellow colored prisms.

11—BIOLOGICAL CHEMISTRY

PAUL E. HOWE

A—GENERAL

FRANK P. UNDERHILL

Oxidation of levulose in absence of oxygen. E. AUBEL AND L. GENEVOIS. *XII Int. Cong. Physiol.* 1926, 11-2.—In anaerobiosis, levulose reduces certain dyes, the rate of reduction of 10^{-3}–10^{-6}*N*-methylene-blue soln. being independent of the dye concn., but increasing with increased p_H value and levulose concn. B. C. A.

Taka-invertase. R. WEIDENAGEN. *Z. Ver. deut. Zuckerind.* **1928**, 125-34.—

Taka-diastase was found to be without action on melibiose, but to hydrolyze raffinose and sucrose at velocities in the ratio of 1:1.96. Conclusion: Taka-invertase is a fructo-invertase and is not assocd. with a melibiase as supposed by Leibowitz and Mechlinski (*C. A.* 20, 3173). The decompn. of raffinose was complete within 24 hrs., and even after 96 hrs. no carbohydrates other than melibiose and levulose could be detected. The optimum p_H value for taka-invertase is about 5.0. Evidence for and against the existence of gluco- and fructo-invertases is considered. B. C. A.

The chemical and physical composition of protoplasm. V. V. Lepeshkin. Univ. of Ill. *Science* 68, 45-8(1928).—The principal components of protoplasm are proteins and lipoids (fats, sterols and phosphatides). Carbohydrates and protein decompn. products may or may not be present, while small amts. of salts are always present. The proteins and lipoids are probably in chem. combination with each other but the compds. are so unstable that they can often be destroyed even by purely mech. forces. The selective permeability of living protoplasm, the very different permeability of the proteins and lipoids from dead protoplasm and the fact that death is caused by reagents that react either with proteins or with lipoids indicate that proteins and lipoids are combined with each other. Living protoplasm is in the hydrophilic colloid state as proved by the extreme ease with which it undergoes change in consistency. Ordinarily it is liquid but it readily becomes rigid in part or even in the whole mass. The protein-lipoid compds. form the dispersion medium of the colloid and for that reason anything that alters either the protein or the lipoid destroys the stability of the colloid and causes death. F. L. Browne

The stability of colloidal ferrous phosphate prepared with gelatin or blood serum. Mariano Messini. *Kolloid-Z.* 45, 322-5(1928).—Since intravenously or subcutaneously injected ferrous salts are changed to colloidal $Fe_3(PO_4)_2$, the stability of colloidal $Fe_3(PO_4)_2$ in the presence of gelatin or of blood serum was studied. The sols were made by mixing 0.3 *N* soln. of $FeSO_4$ contg. gelatin or serum with 0.3 *N* soln. of Na_3PO_4 also contg. gelatin or serum, and noting how long the sols remained stable. The stability increases with the content of protecting colloid until a max. is reached beyond which no further increase results. The stability is greater the more dil. the $Fe_3(PO_4)_2$. F. L. Browne

Kidney phosphatase and its activation. II. Holger Erdtman. Univ. Stockholm. *Z. physiol. Chem.* 177, 211-20(1928); cf. *C. A.* 22, 435.—The activator present in meat ext. which increases the activity of kidney phosphatase toward glycerophosphate evidently does not function merely as a protective substance. No difference in extent of activation is noted when the enzyme is given a preliminary treatment for 24 hrs. at p_H 8.8° and 30° with or without activator. The activator has a greater affinity for phosphate than for enzyme and the affinity of the enzyme for the activator-phosphate complex is negli ible. In the purified activator prepns., however, a small amt. of activator corresponds to a much greater amt. of liberated phosphate. It is not probable therefore that the activator diminishes an inhibition of enzyme by phosphate liberated during the reaction It seems more likely that the enzyme-activator complex is more resistant to inhibition by phosphate than is the enzyme itself and a sort of buffer effect is thus obtained. The activation of zymophosphate cleavage, on the other hand, was not so great as that of glycerophosphate cleavage, due to a small amt. of activator already present in the zymophosphate prepn. Purification of the activator obtained from meat ext. by Pb and Ba pptns. and recrystn. of the H_2SO_4 salt of the basic constituent yielded $MgSO_4$ which also had the properties of an activator. It is not certain, however, that the activating properties of the meat ext. reside entirely in the Mg ions present. III. *Ibid* 231-6.—The activation of kidney phosphatase by $MgSO_4$ is more or less specific. $CaSO_4$ and $BeSO_4$ gave no such activation, and $ZnSO_4$ showed a distinct inhibition in the same mol. concns. at which the activation by $MgSO_4$ was very marked. Purification of the enzyme may be effected in several ways. The filtered ext. after 7 days autolysis is more active than after 2 days autolysis, but less active than the fresh turbid ext. An ext. from the dried prepn. is considerably more active, and by $Al(OH)_3$ adsorption the activity is increased still further. Elution may be performed by NH_4OH or Na_2HPO_4, the latter giving a more active product but in lower yield. Kaolin also adsorbs the enzyme, but neither the adsorption nor the elution is sufficiently selective for purification purposes. The purest prepn., which was obtained by $Al(OH)_3$ adsorption and Na_2HPO_4 elution, gave a positive Millon reaction, negative or doubtful Molisch reaction, and indistinct biuret reaction. A. W. Dox

Variations in serum calcium. P. Mescltskii. Leningrad Medical Institute. *Z. ges. exptl. Med.* 55, 13-6(1927).—Ca was detd. in cats by Clark's method (*C. A.*

16, 941) except that 3% NH_4 oxalate was used. Starvation increased the blood Ca. Following kidney extirpation there was a rise in the first 24–48 hrs. followed by a sharp fall. $HgCl_2$ poisoning and splenectomy lowered the blood Ca. Normal values for cats were 14.69 for males and 14.57 mg. per 100-cc. blood for females. F. L. DUNN

The disintegration of potassium myronate by animal sulfatase. IX. Sulfatase. CARL NEUBURG AND JOACHIM WAGNER. Kaiser Wilhelm-Institut. *Z. ges. exptl. Med.* **56**, 334–43; cf. *C. A.* **21**, 923–4.—Potassium myronate was obtained from black mustard seeds (*Brassica nigra*) and mixed with liver, muscle and kidney tissue of horses and rabbits, and the amt. of sulfate formed detd. as $BaSO_4$. Only negligible amts. were found. F. L. DUNN

Adsorption therapy. H. BECHHOLD AND L. KEINER. Inst. Kolloidforschung zu [Fra]nkfort. *Z. ges. exptl. Med.* **56**, 543–61(1927).—A study of the effect of various adsorbing agents used singly and in combination and their effectiveness for bacteria, toxins and enzymes. F. L. DUNN

Odor and constitution among the mustard oils. IV. Effect of fluorine substitution. G. MALCOLM DYSON. *Perfumery Essential Oil Record* **19**, 341–2(1928); cf. *C. A.* **22**, 3174.—It has already been shown that the entrance of Cl, Br and I into the nucleus of aromatic mustard oils is attended with a modification in the odor which is dependent on the position taken up by the entering halogen atom. In general, the effect of a halogen substituent in the para position is to give a mustard oil with a sweet anise odor—the sweetness of the odor increasing with increase of wt. of the halogen atom—becoming a max. with *p*-iodophenyl mustard oil. A series of aromatic mustard oils has now been prepd. contg. F in place of the halogens previously used, in order that a systematic comparison of the odors of these series might be made. Examn. of the chem. reactivity of the mustard oils substituted by F, Cl, Br and I in the para position has revealed that as far as the NCS group is concerned there is little to choose between the 3 last compds., but that the F compd. occupies a position intermediate between that of the others and of the unsubstituted phenyl mustard oil. Furthermore, a connection can be traced between this variation in chem. activity and the periodic motion associated with the C-S electron pairs which, it may be added, depends in turn upon the atomic vols. of the substituent groups F, Cl, Br and I. Thus, the larger the atomic vol. occupied by the halogen, the greater the alteration of the orbits of the C-S electron pairs, and consequently the greater enhancement of the reactivity of the NCS group. Arguing from these premises it seems more than probable that the odor of the fluoro compds., depending as it does on the intramol. vibrations, will be parallel to the chem. reactivity, and that the osmic frequencies will be intermediate between those of the simple unsubstituted phenyl mustard oil and its corresponding *p*-chloro, -bromo and -iodo derivs. This conclusion was found justified in the case of the para compds. Of the *m*-fluoro mustard oils examd., three (of which 2 contained the Me group) have very pronounced "true" mustard oil odors. It should be noted also in this connection that 3- and 4-fluorophenyl mustard oils exert a pronounced vesicant action on the skin, which is quite appreciable in the cases of the other corresponding halogen compds. So far, the attempts to prep. the 2-fluoroaniline required for the prepn. of 2-fluorophenyl mustard oil have been unsuccessful. 3-Fluoro-4-nitroaniline was, however, prepd., and converted by the action of $CSCl_2$ upon its HCl-salt into 3-fluoro-4-nitrophenyl mustard oil. In common with the other mustard oils contg. the NO_2 group this compd. is without any characteristic odor. These expts. serve to show that for purposes of practical perfumery the aromatic fluoro mustard oils are unsuitable, and that attention must be concd., as far as blending is concerned, upon the analogous Cl and Br compds. W. O. E.

The resorption of copper and ferrocyanide ions by coagulated proteins. BYRON M. HENDRIX. Univ. Texas. *J. Biol. Chem.* **78**, 655–60(1928).—Coagulated egg albumin adsorbs Cu^{++} and $Fe(CN)_6^{----}$ from soln. The amt. of Cu^{++} absorbed increases with the p_H up to p_H 6.9 while the amt. of $Fe(CN)_6^{----}$ absorbed decreases with increasing p_H. ARTHUR GROLLMAN

Ernst Henry Starling (1866–1927). C. L. E. *Biochem. J.* **22**, 618–20(1928).—Obituary notice. BENJAMIN HARROW

The reducing power of cysteine. E. C. KENDALL AND D. F. LOEWEN. Mayo Foundation, Rochester, Minn. *Biochem. J.* **22**, 649–68(1928).—A reply to Dixon and Tunnicliffe (*C. A.* **22**, 437). Cysteine cannot reduce indigo carmine and it cannot oxidize reduced indigo carmine or reduced indigo in the absence of an activating agent, which is produced through the action of O_2 or Na disulfide on indigo carmine. Fe

cannot activate the —SH or —SS grouping, but it can influence the velocity of reaction between O_2 and indigo carmine. The activating agent appears to be an unstable O_2 or S addn. product of indigo carmine and its action involves the activation of the S atom. BENJAMIN HARROW

Mechanism of oxidation-reduction potential. I. The oxidation-reduction potential of cysteine and cystine. E. C. KENDALL AND D. F. LOEWEN. Mayo Foundation, Rochester, Minn. *Biochem. J.* **22,** 669–82(1928).—The authors take issue with Dixon's hypothesis (*C. A.* **21,** 2596) of a "steady state" depending on a kinetic equil. between the dissocn. of H_2 from cysteine and diffusion of H_2 from the surface of the metal electrode. The drift in the reduction potential with a Pt electrode has been shown to be due to traces of O_2, or oxidizing substances, adsorbed on the surface of the metal. When cysteine is oxidized it does not form cystine at once but an intermediate compd. BENJAMIN HARROW

The reduction potential of cysteine. D. C. HARRISON AND J. H. QUASTEL. Biochem. Lab., Cambridge. *Biochem J.* **22,** 683–8(1928).—Traces of metals which bring about a catalytic effect with cysteine do not bring about the increase in neg. reduction potential which is demanded on Dixon's hypothesis (*C. A.* **21,** 2596). BENJAMIN HARROW

Some properties of the dehydrogenating enzymes of bacteria. J. H. QUASTEL AND W. R. WOOLDRIDGE. Biochem. Lab., Cambridge. *Biochem. J.* **22,** 689–702(1928).—The *B. coli* enzyme which activates lactic acid as a H donator adsorbs compounds of the type —CO—COH*— or —CHOH—COH*, where H* is mobile, the compd. having acidic properties. The enzyme which activates succinic acid adsorbs compds. of the type —C—CH—COOH or —C—CH_2—COOH. The reduction of methylene blue by glucose in the presence of bacteria is independent of the intermediate production of lactic acid. The effect of toluene can be explained on the "active center hypothesis" (*C. A.* **21,** 2715). A "soluble" prepn. of the lactic acid enzyme has the same adsorbing power on a particular type of compd. as has the lactic acid enzyme of *B. coli.* B. H.

Inhibitory effect of sugars on hemolysis by sodium taurocholate. ERIC PONDER AND J. F. YEAGER. New York University. *Biochem. J.* **22,** 703–10(1928).—The inhibitory action of the sugars is a double one both in saponin–sugar–cell systems (*A*) and taurocholate–sugar–cell systems (*B*). In (*A*) the principal effect is on the cells themselves rather than on the activity of the lysin. In (*B*) the effect of the lysin may be very much greater than that of the cells themselves. The greatest depression of the activity of the lysin in taurochlolate–sugar–cell systems occurs when the lysin is in those concns. in which it is most unstable. BENJAMIN HARROW

Artefacts as a guide to the chemistry of the cell. C. E. WALKER. Univ. Liverpool. *Proc. Roy. Soc.* (London) **B103,** 397–403(1928).—During fixation, the position and arrangement of the lipins in relation to the nucleus are probably controlled by some chem. change in the latter. When yellow P is dissolved in either Me myristate or Me laurate, and this lipin is then added as an emulsion to certain colloidal mixts., which are then kept at a temp. of 30°, microscopic examn. after fixation and treatment with OsO_4 shows that a large proportion of the lipins has become distributed over the globules in approx. 2 hrs., and that most of the fatty acids have become satd. or oxidized in 24 hrs. JOSEPH S. HEPBURN

Influence of the rays of the sun on the basal metabolism of man. JAROSLAV MĚLKA. Komensky Univ., Bratislava. *Bratislav. Lekárske Listy* **6,** 50–61(1926).—A 14 to 47% increase in O_2 consumption was found in persons exposed to the rays of the sun during the noon hours of July. WILLIAM J. HUSA

The amount of cholesterol in the blood serum of middle-aged persons. JAROSLAV MĚLKA. Komensky Univ., Bratislava. *Bratislav. Lekárske Listy* **6,** 296–9(1927).—Of 50 healthy, middle-aged persons, 27 were found to have hypercholesterolemia; the cholesterol content in these cases varied from 190 to 307 mg. in 100 cc. of blood serum. WILLIAM J. HUSA

The permeability of the surface between blood and cerebrospinal fluid—a problem. ERNST WIECHMANN. *Krankheitsforsch.* **5,** 150–66(1927).—If the surface between the blood and the cerebrospinal fluid is regarded as a dead membrane, there should be set up a membrane equil. A survey of the literature shows that the ion concns. in the blood and liquor do not fulfil the conditions of the Donnan equation. P. Y. J.

The action of neutral salts in enzymic processes. The effect of bromides on salivary amylase. KSHITISH CHANDRA SEN. Allahabad Univ. *J. Indian Chem. Soc.* **5,** 245–9(1928).—The amyloclastic action of salivary amylase in the presence of a phosphate buffer is studied. The range of p_H from 5.8 to 6.8 was investigated and NaCl added to activate the enzyme. The optimum p_H for amyloclastic action lies about

6.7. The addn. of NaCl shows a normal accelerating effect and higher concns. of phosphate buffer do not assist. Low concns. of KBr increase the chromic period but higher concns. of KBr (0.10 m. per l.) decrease this time which is in agreement with Thomas (*C. A.* **11**, 2336). With NaBr only an increase in the chromic period is noted. In studying the sacharogenic effect of KBr and NaBr with no buffer it is found that in the concns. studied (up to 0.2 m.) a depression of the activity of the enzyme is noted. D. H. POWERS

Some effects of x-radiation on blood. W. V. MAYNEORD AND A. PINEY. London Cancer Hospital. *Brit. J. Radiology, New Series* **1**, 257–82(1928).—Rabbits were irradiated from below with x-rays from a Coolidge tube run at 90 kv.-peak, 2.9 ma., the target being 24.5 cm. from the animal. The radiation had a half value layer of 0.295 mm. Al and an av. intensity of 19 R. per min. Large doses (7920 R.) caused extreme lymphocytopenia, persisting until death, neutrophilia, which decreased toward death, and monocytosis, which appeared late and lasted until death. No change in red corpuscles was found. Death took place in about 3 weeks. Smaller doses (500 R.) reduced the lymphocytes and increased the neutrophiles, but both of these returned to normal some weeks after irradiation. Monocytosis was slight or lacking. Effects of divided doses were more intense and prolonged than those of a single dose. E. H. QUIMBY

Transformation of uric acid to urea by sulfo-chromic oxidation. (MLLE.) J. SCHWANDER AND H. CORDEBARD. *Bull. soc. chim. biol.* **10**, 920–31(1928).—The hydrolysis of urea by H_2SO_4 was greater as the acid was nearer to the theoretical amt. for the transformation of the urea. The degree of hydrolysis also varied with the temp. and with the time. The addn. of $K_2Cr_2O_7$ to the H_2SO_4 solns. of urea changed none of these general conclusions, but promoted the hydrolysis by lessening the time and lowering the temp. With the sulfo-chromic mixt. at 50 to 60% of the H_2SO_4 present, the transformation of uric acid to urea on the boiling water bath (98°) was 95 to 96% and to NH_3 3.0 to 3.5%. L. W. RIGGS

Experiments with collodion tubes substituting blood vessels. I. Formation of endothelium by the monocytes of the blood. TIVADAR HUZELLA. *Magyar Orvosi Arch.* **29**, 101–13(1928); cf. *C. A.* **22**, 2586.—By inserting small collodion tubes into the blood vessels of animals, the formation of endothelium could be followed along the wall of the artificial vessel. The most essential wall of the closed blood vessel system is a fine membrane which coagulates between the blood plasma and the tissue fluid. L. W. RIGGS

Effect of Röntgen rays on the blood and blood-forming organs of white rats. E. WOENCKHAUS. *Arch. exptl. Path. Pharmakol* **131**, 335–56(1928).—In young, growing rats (during the first 4 weeks of life) a severe anemia may be produced by small doses of x-rays. Keeping the rats on a rickets-producing diet does not intensify the effects of irradiation. Protection of the spleen and liver from the x-rays prevents the development of anemia. G. H. S.

Effect of short wave-length rays on the fluorescence of proteins and their split products. PAUL WELS. Univ. Greifswald. *Arch. ges. Physiol.* (Pflüger's) **219**, 738–52 (1928).—Serum euglobulin shows a bluish fluorescence when exposed through a dark filter to ultra-violet light, and when irradiated with unfiltered rays from a Hg lamp the fluorescence is increased. The effect is quantitatively related to strength of dosage. After quartz light treatment, with fluorescence the euglobulin soln. becomes turbid. Protein-split products behave in a similar fashion. The fluorescent effects are in large part detd. by the presence of O. G. H. S.

Influence of light environment on the organic constitution of normal rabbits with especial reference to the action of neon light. WADE H. BROWN AND MARION HOWARD. Rockefeller Inst. for Med. Research. *J. Exptl. Med.* **48**, 567–89(1928); cf. *C. A.* **22**, 3691.—The light environment produces an effect on the phys. constitution of rabbits which was comparable to the effects produced on the functional activity of the same animals. C. J. WEST

Measurement of the electrokinetic potential on protein (BRIGGS) 2.

Determination of urobilinogen in urine and feces. A. ADLER. *Deut. Arch. klin. Med.* **154,** 238–48(1927).—Isolation of urobilinogen is necessary for its accurate detn. A suitable extn. app. has been constructed. B. C. A.

Determination of urobilinogen in feces and urine by the new extraction method. A. ADLER AND M. BRESSEL. *Deut. Arch. klin. Med.* **155,** 326–41(1927).—Ehrlich's urobilinogen reaction is quant. only under definite conditions. In the chloroform ext. of urine or feces the conversion of the chromogen into urobilin takes place much more slowly than in urine or after addn. of alc., being maximal when 1 cc. of Ehrlich's reagent and 2 cc. of abs. alc. are added to 2 cc. of chloroform ext. Normally, 1–3 mg. per day appear in the urine; in urine and feces together, 100 mg. B. C. A.

The imperfect working of hematoxylin as a nuclear stain. G. C. VAN WALSEM. *Nederland. Tijdschr. Geneeskunde* **72,** I, 1808–12(1928).—Hematoxylin fails to stain differentially the single minute structural elements of the nucleus. W. obtains a satisfactory differential staining by adding an alk. soln. of Br_2 to the stain. R. B.

The benzidine and guaiacum reactions in urine with special consideration of the role of uric acid in these reactions. OSKAR WELTMANN AND WALTER WASCHATA. III. Mediz. Universitätsklinik, Wien. *Wiener klin. Wochschr.* **41,** 1041–3(1928).—A discussion. D. B. DILL

A simple nitrite reaction in urine. LUDWIG POPPER AND SIEGFRIED WEISS. I. Med. Abteilung des Allg. Krankenhauses in Wien. *Wiener klin. Wochschr.* **41,** 1081–2(1928); cf. *C. A.* **7,** 1069.—Benzidine in AcOH soln. added to urine gives an orange-red color in the presence of nitrites. D. B. DILL

Determination of carbon monoxide in blood. W. M. M. PILAAR. Tech. Hoogeschool Delft. *Chem. Weekblad* **25,** 509–13(1928).—The Cohen-Tervaert method (*C. A.* **19,** 1877) for detg. CO in blood is based on the liberation of CO by vacuum and addn. of $K_3Fe(CN)_6$, reaction of the gas in the presence of air with I_2O_5 at 150°, absorption of the liberated I in KI soln. and titration with $Na_2S_2O_3$. It has the disadvantage of requiring 10 cc. of blood, the app. must be swept out with 1–2 l. of purified air, loss of I occurs through absorption by rubber stoppers and connections, and the concn. of KI recommended is insufficient. All of these objections are overcome by a modification of the app. and technic, whereby a micro method has been developed requiring only 1 cc. of blood. Rubber stoppers and connections are replaced by ground glass joints, the I_2O_5 is heated in an air bath instead of an oil bath, and the I absorbed by the KI is titrated from a micro buret directly in the absorption chamber without transfer to another vessel. Only 150–300 cc. of air are required to sweep out the app. and the time consumed is 25–40 min. instead of 1–1.5 hrs. The app. is described in detail and certain precautions to be observed are pointed out. The I_2O_5 is rendered more efficient by mixing with glass wool and is given a preliminary heating at 200–300°. With very pure I_2O_5 correction is made for a small negative blank. For details of operation the original paper should be consulted. A. W. DOX

A method for measuring the hydrogen-ion concentration in very small volumes. S. S. GIRGOLAV AND I. I. SHUKOV. Med. Akad. and Univ. Leningrad. *Z. ges. exptl. Med.* **56,** 710–3(1927).—A modification of the Schade method (cf. *C. A.* **16,** 120). F. L. DUNN

Sugar reduction agents. ENGELB. SCHLECHT. *Pharm. Ztg.* **73,** 1006–7 (1928).—The claims of Brandrup (*Apoth. Ztg.* **43,** 373; *C. A.* **22,** 1825) respecting the influence of arbutin-contg. urine in application of sugar tests are questioned. W. O. E.

Use of fermentation saccharometer. KARL EBERT. Fähr-Vegesack. *Pharm. Ztg.* **73,** 1007(1928).—Attention is directed to the accuracy of this app. in testing for sugar in urine, especially in questionable cases where the Nylander or Fehling tests have been negative. W. O. E.

Note on the use of fermentation saccharometers. KARL EBERT. *Pharm. Ztg.* **73,** 1099(1928); cf. preceding abstract.—There is substantial agreement with E.'s criticisms among co-workers in this field. W. O. E.

The estimation of aluminum in animal tissues. V. C. MYERS, J. W. MULL AND D. B. MORRISON. State Univ. of Iowa. *J. Biol. Chem.* **78,** 595–604(1928).—A colorimetric method is described for estg. the minute quantities of Al found in body tissues. The method consists in digestion with a mixt. of H_2SO_4 and $HClO_4$; pptn. of the Al and some Fe by NH_4OH; removal of the Fe; and the development of a color reaction upon the Al with the NH_4 salt of aurin tricarboxylic acid. By using reagents of the

very highest purity and with proper precautions, the results by the method are accurate within 10%. ARTHUR GROLLMAN

... histidine and arginine. IV. The preparation of histidine. ... New Haven ...

from coagulated blood cells ... dine pptd. as its Ag compd. at p_H 7.4. It is then pptd. with ... and crystd. at its isoelec. pt. The product is purified by crystn. of the dihydrochloride. A yield of 4 to 5% of the dry blood cells is obtained. ARTHUR GROLLMAN

A micro-method for the determination of potassium as iodoplatinate. ALFRED SHOHL AND HELEN B. BENNETT. Yale Univ. *J. Biol. Chem.* **78**, 643-51(1928).—A procedure is described for detg. 0.1 mg. of K with an accuracy of ±4%. The deproteinized material is ashed and the K pptd. as the chloroplatinate. The latter is then converted to the iodoplatinate by means of KI in acid soln. and detd. colorimetrically against known standards. ARTHUR GROLLMAN

The fractionation of serum proteins by means of ammonium sulfate. ANNA MUSCHEL. Hospital for Joint Diseases, N. Y. *J. Biol. Chem.* **78**, 715-8(1928).—The method usually employed was modified by aerating the soln. at 60-70° to remove the free NH_3 of the albumin soln. and by adding 0.2 cc of a 30% H_2O_2 soln. to hasten oxidation in the digestion mixt. ARTHUR GROLLMAN

Gasometric determination of hemoglobin by the carbon monoxide capacity method. D. D. VAN SLYKE AND ALMA HILLER. Rockefeller Institute. *J. Biol. Chem.* **78**, 807-19(1928).—Hemoglobin is detd. by measuring the vol. of CO combined with it, using the manometric gas app. of Van Slyke and Neill. The results agree perfectly with those derived from O capacity values. ARTHUR GROLLMAN

A modified method for the determination of hippuric acid and free benzoic acid in the urine of cattle. F. J. WARTH AND N. C. D. GUPTA. Imperial Dept. of Agriculture in India, Bangalore. *Biochem. J.* **22**, 621-7(1928).—The novelty in the method consists in estg. the liberated benzoic acid with the aid of partition coeffs. B. H.

The morphology of lipoids. PAUL KIMMELSTIEL *Krankheitsforsch.* **5**, 403-18 (1928).—The following method is recommended for the identification of intra- and extracellular lipoids in tissues previously extd. with acetone. The section is washed with water and treated for 5 min. with an anhyd satd. soln. of ponceau red in acetone; by this treatment the entire section is intensely colored. It is then dipped for a moment into a 55-60% aq. soln. of acetone; this soln. dissolves the dye more rapidly from the non-lipoid tissues and permits differentiation by color. It is important that the concn of acetone in this soln. be carefully regulated; too high a proportion of acetone removes all the dye from the tissue; too little causes ppts. which later interfere with the examn of the section. The section is now washed with distd. water; nuclear staining and all subsequent treatment follow the usual procedure for staining with ponceau or sudan III. The section as a whole is rose red; the fat an intense dark red. Illustrations are given to show the combined lipoid in the atheromatous aorta, in the brain, etc. P. Y. JACKSON

Uric acid determination in blood according to Benedict. S. BUCHTEJEV. *Moskovskij med. zhurnal* **7**, 5-7(1927); *Ber. ges. Physiol. exptl. Pharmakol.* **44**, 667-8.—A *micromodification* of Benedict's method. To 3.4 cc. distd. water in a test tube add 0.2 cc. blood, 0.2 cc. Na_2WO_4, then dropwise 0.2 cc. 0.66 N H_2SO_4. Mix thoroughly, allow to stand 30-45 min. and centrifuge. To 1 cc. of the centrifuged soln., add 0.4 cc. 5% NaCNO and 0.1 cc. Benedict reagent, shake vigorously and heat 1.5 min. on the water bath, cool and det. in Autenrieth's colorimeter. The results agree with macro-detns MARY JACOBSEN

Estimation of sulfur in blood and in organic products. A. LESURE AND A. DUNEZ *Bull. soc. chim. biol.* **10**, 879-90(1928).—In detg. S by the volumetric benzidine method of Pohorecka-Lelesz (cf. *C. A.* **21**, 2145), an error may be introduced by the use of acetone contg. S as an impurity. With care to use S-free acetone this method of detg. S in body fluids and org. material is recommended. L. W. RIGGS

Quantitative estimation of indican in the blood serum and urine as a kidney functioning test in surgery. MASAO MUTO. *Tôhoku J. Exptl. Med.* **11**, 57-77(1928).—Thirty-one references to the literature are given. The quant. estn. of indican in blood and urine by the method of Jolles-Rosenberg, especially in combination with ureteral catherization, may be performed with sufficient accuracy for testing the kidney functioning in surgical cases. At the same time results by this method should be checked by other methods of testing kidney functioning. L. W. RIGGS

Studies on lipochromes. II. The identification of carotin, xanthophyll and asso-

ciated lipoids in tissues. Charles L. Connor. Harvard. *Am. J. Path.* **4**, 235–44 (1928); cf. *C. A.* **22**, 2763.—Carotin and xanthophyll, the two common lipochromes, do not stain by any of the fat stains ordinarily employed to differentiate them. When associated with a lipoid which does stain, this lipoid takes a blue stain with Nile blue sulfate, and may therefore be cholesterol, cholesterol ester, soap, fatty acid or lecithin, since it is anisotropic, and carotin and xanthophyll are not. When a pigment is present in tissues associated with a substance which takes a specific stain for fat, this pigment may be assumed to be a lipochrome, but this is not invariably so. Yellow pigment which tends to coalesce when treated with weak alc. KOH and formalin, or which crystallizes in the tissue after such treatment, is probably lipochrome. Pigment which disappears or loses its color after treatment with a strong soln. of $FeCl_3$ (or other oxidizing agent), if not continued too long, may be assumed to be lipochrome. Pigment which is sol. in the usual fat solvents (ether, petroleum ether, $CHCl_3$, etc.) is probably lipochrome, but this treatment, in order to be effective and of differential value, must be prolonged and used after dehydration of the tissue with alc. or acetone. Nile blue sulfate differentiates only neutral fats from all other lipoids, neutral fat staining red, and all other lipoids, which stain, blue. Lecithin, which takes a somewhat lighter stain than the other blue-staining lipoids, may possibly be differentiated from them but careful timing of the staining process is necessary. **IV. The nature of the pigments in certain organs.** *Ibid* 293–308.—A new technic was developed which consisted of the following. The organs were dissolved and saponified in alc. KOH, dehydrated, and extd. with petroleum ether. In some cases the resultant pigment was identified by spectroscopic examination. The fat stains used were Scharlach R and an aq. soln. of Nile blue sulfate. The precursor of melanin was identified by the Dopa reaction with 3-4 dihydroxyphenylalanine. Basic fuchsin was used to stain hemofuscin and it also stained lipoids and the cytoplasmic granules of tissue mast cells. Mallory's iron reaction with ammonium sulfhydrate, followed by $K_3Fe(CN)_6$ and acetic acid, was used. The results of study of the types of pigment found in the various tissues were as follows. *Skin*—melanin and lipochrome; also, in hemochromatosis; hemofuscin and hemosiderin. *Fat*—lipochrome. *Heart, intestinal muscle, seminal vesicles, testicles, prostate*—hemofuscin and hemosiderin. Increased in old age, brown atrophy and hemochromatosis. *Liver* and *spleen*—hemofuscin and hemosiderin besides bile pigment. Increased in old age, brown atrophy and hemochromatosis. *Adrenal cortex*—lipochrome. *Adrenal medulla*—probably melanin. *Corpus luteum*—lipochrome. F. B. Seibert

Simple and quick method for the determination of organic combined iodine in body fluids. Paul Kuhn and Arnold Loeser. Univ. Köln. *Arch. exptl. Path. Pharm.* **131**, 262–7(1928).—The org. materials are destroyed by Na and saltpeter, and after the addn. of water and dil. H_2SO_4 the I is detd. by shaking with $CHCl_3$ and adding $Na_2S_2O_3$. G. H. S.

Determination of bismuth in urine. George Ciogolea. Univ. of Bucharest. *Bul. soc. chim. Roumania* **10**, 55–60(1928).—A study of the Cuny and Poirot method (cf. *C. A.* **18**, 208) for its application to urine. This method, following directions given by C., gives result accurate to $\pm 3\%$. P. Thomasset

Apparatus for treatment of "blood stream infections" with ultra-violet radiations. Lester A. Edblom and Emmet K. Knott. U. S. 1,683,877, Sept. 11.

C—BACTERIOLOGY

CHARLES B. MORREY

Photo-biological action of light. J. Risler, A. Philibert and J. Courtier. *Compt. rend.* **186**, 1152–4(1928).—No bacteriophage is obtained by the addn. of the filtrate of a culture of organisms, previously killed by the action of light in the presence of fluorescent dyes, to a similar living culture. *B. tuberculosis* is partly destroyed by the light of the Ne lamp in the presence of many dyes (especially those of the pinacyanol class). The great bactericidal action of the light produced by the elec. volatilization of Al wire is described. B. C. A.

Changes produced in meat extracts by the bacterium Staphylococcus aureus. Application of the alcohol titration methods. F. W. Foreman and G. S. Smith. *Dept. Sci. Ind. Research, Food Investigations* **1928**; *Special Rept.* No. **31**, 97 pp.—The ext. used was that of ox heart made with plain tap water and concd. to 1/4 or 1/16 of its original vol. The growth of the bacteria in this medium at 37° was compared over extended periods with the variation in the proportion of amino acids, volatile bases, volatile and non-volatile acids, etc., as detd. by the alc. titration method (cf. Foreman, *C. A.*

22, 2182). The organisms exhibited various periods of growth, each of which was characterized by a particular chem. change. In the 1st period the rate of growth reached a max. on the 4th day and resulted in the production 1st of volatile bases, then of volatile and non-volatile acid radicals, and finally of non-volatile acid radicals alone. A second max. occurred on the 28th day, when non-volatile acid radicals were converted into the equiv. amt. of volatile acid radicals During a third period of growth the no. of organisms gradually diminished, while the decline in the non-volatile acid radicals continued practically to zero with production of CO_2, the volatile acid radicals remaining approx. const. During the later stages of prolonged incubation the organisms destroyed the volatile acid radicals at room temp., but at 37° they attacked the amino acids and nonvolatile amines in preference. B. C. A.

Control of reaction in cultures and enzymic digests. Comparison of the effects of certain salts on changes in p_H and changes in absolute $[H^+]$ with reference to enzyme action. Role of creatinine in the control of reaction in cultures. F. W. Foreman and G. S. G. Smith. *Dept. Sci. Ind. Research, Food Investigations* **1928**; *Special Rept.* No. **32**, 27 pp.—Examn. of the p_H value and titratable acidity of ox-heart exts. in which *Staphylococcus aureus* has been growing for varying periods indicates that phosphates and creatinine, which are present in the ratio of 1.7:3.0, are largely responsible for the resistance to changes of p_H on addn. of acid. The influence of salts on the activities of enzymes and bacteria in media should be considered from the point of view of their effect not only on the p_H values (buffer action), but also on the abs. $[H^+]$ and $[OH^-]$ (depressor effect). In the region of $[H^+]$, where phosphates have little depressor effect, the action of creatinine in facilitating the continued growth of acid-producing organisms is demonstrated B. C. A.

Behavior of d'Herelle's lytic principle (bacteriophage) toward collodion membranes and in distilled water. L. Villa. *Folia clin. chim. microscop.* **1**, 52–7(1926).—The lytic principle behaves like a colloid with large micelles It does not pass a collodion filter. In distilled water the active bacteriophage can be isolated and is apparently visible with an ultramicroscope. B. C. A.

Studies of pathological protein destruction. II. The butyl alcohol soluble mono-amino acids obtained from the proteolytic hydrolysis of casein by the colon bacillus. M. Schierge. Med. Klin. Leipzig. *Z. ges. exptl. Med.* **53**, 44–56(1926); cf. *C. A.* **21**, 434.—Three hundred g. casein was digested for 9 months with the protease obtained from 8 l. of a *B coli* culture. 0.6 g. tyrosine, 0.5 g. leucine; 30 mg. phenylalanine and some tryptophan were obtained. Bibliography. F. L. Dunn

Bacterial oxidation. Gilvert and Subramanian. *J. Ind. Inst. Sci.* **8**, 147–72 (1928); *Deut. Essigind.* **32**, 281–3, 289–92, 299–301(1928) —A series of expts. on the oxidation of EtOH to AcOH is described and the results obtained thereby are tabulated. Among the results accomplished were: development of vigorous pure bacterial cultures for mass production, involving exptl. study of the influence of varying quantities of inoculating cultures; the accelerating influence of certain catalysts, particularly EtOAc and Mn salts; the favorable influence of forced aeration in the slow acidification process was demonstrated, although a critical line of demarcation exists beyond which aeration should not go, this limit depending on the content of bacteria in the culture liquid, as also on the presence of EtOH; it is shown that up to 4% the progress of acid formation is independent of the alc. concn. employed; the acidification process under forced aeration was carried on from 8.8%, whereby 0.8% by vol. alc. was oxidized daily, the process being continued successfully to the end; in order to protect the cultures from infection a liquid temp. of 32° is necessary; the oxidation of AcOH in CO_2 was systematically studied, as also the influence of foreign organisms; the checking effect of $Ca(OAc)_2$ was detd W. O. E.

Euglena in relation to combined nitrogen. Daggmar H. Peterson. *Rep N. J. Agr. Expt. Sta., Dept. Sewage Disposal* **1927**, 310–5; *U. S. Pub. Health Eng. Abstract* **E-637b**, 19(1928).—A single expt. was made using liquid from a resting Imhoff tank which contained chlorophyll-bearing *Euglena polymorpha*. A portion of this was used as a control and to another portion was added lactic acid to the amt. of 0.6%. By making frequent chem. analyses for ammonia N and total N, p_H and detg the bacterial and protozoa counts, P. concludes that colorless *Euglena* in a nutritive medium consumes rather than increases the amt. of combined N. C. R Fellers

The action of hydrogen peroxide upon aerobic spore-forming organisms. Hedwigh Rieger and Richard Trauner. *Arch. Hyg.* **98**, 176–90(1927).—H_2O_2 is effective sporicide, and resembles steam in its effect. Even with very high conc of H_2O_2 considerable time is required for the action to be complete; while small conc are sufficient if time is allowed. P. Y. Jackso

Bacteriophage. Investigation of the colon bacteria of cattle. GEORG MAJER. *Arch. Hyg.* 98, 195–228(1927).—The bacteriophage reaction occurs in milk and milk products. By the action of a bacteriophage adapted to an acid medium the swelling of cheese may be decreased. The action of colibacteriophage is halted by the presence of quinine-HCl. The bacteriophage cannot diffuse through an agar gel, but an enzyme-like substance is produced which does diffuse through the gel. P. Y. JACKSON

An investigation of the biology of Oidium albicans and of the pathogenesis of disease due to this organism. I. KARL KRAUSPE. *Krankheitforsch.* 4, 1–28(1927).—The formation of thread-like growths of *Oidium albicans* takes place best with a p_H near the neutral point and with a const. low surface tension of the surrounding medium, such as is secured with solns. of dextrin and gelatin. A strongly acid or alk. reaction, or a high surface tension causes the growth of yeast-like cells of the organism. The extremes of p_H between which the organism lives are about 3.8–8.1. When the organism is grown upon solns. of various sugars, glycerol or bouillon in 1% concn., it thrives only when mannitol, grape sugar, or milk sugar is used; in these solns. much acid was formed by the growth process. Such body fluids as bile, solns. of the bile acid salts, blood, serum, etc., were physicochemically suitable for the growth of the organism. II. *Ibid* 4, 139–63.—Peroral infection of white rats or white mice with *Oidium albicans* leads to a growth of the organism in the esophagus and stomach; sometimes the esophagus is completely closed. In starving rats the course of infection is sometimes more rapid. When the animals are given strong acid or alk. food no special symptoms are observed; but the form of the organism is observed to vary. Continued treatment with the organism leads to a gradual intensification of the symptoms, and frequently to death. P. Y. JACKSON

The effect of oxygen on the motility of cholera vibriones. M. VAN RIEMSDIJK. *Nederland. Tijdschr. Hyg. Microbiol. Serol.* 3, 1–21(1928).—When broth is inoculated with cholera vibriones it first becomes cloudy, then some of the cloudiness rises to the surface covering it with a pellicle. In a hanging drop taken from the pellicle the vibriones (v.) show a very rapid movement which begins to slow down in about 24 hrs. At the same time the v. grow shorter and plumper. Autoagglutination sometimes takes place after several days. In a hanging drop drawn from underneath the pellicle the movement is very slow and hardly discernible from the Brownian movement. About 24 hrs. later the movement becomes rapid and is assocd. with increasing autoagglutination and involution (a great variety of involution forms is shown in drawings). After 3–4 days v. detach themselves from the clumps and resume their rapid motion. Eventually agglutination and immobilization take place. The v. are characterized by great individual variability. The *El Toro* v. differ from the *Metchnikov* v. in that even pellicle v. show slight motility. The rising of some colonies to the surface is attributed to the O_2 need of the "bottom" drop; the agglutination and involution of these v. are a result of O_2 deficiency and of the action of own metabolites as well as of those of the top v. The bottom v. are apparently far more sensitive to stimuli. The clinical and perhaps also the epidemiological behavior of cholera exhibits a certain analogy with this bacteriological "individualism" and sensitization. MARY JACOBSEN

Effect of the nature of peptone on Eijkman's fermentation test. J. DE GRAAF. *Nederland. Tijdschr. Hyg. Microbiol. Serol.* 3, 22–38(1928) —It has been observed that water of the Maas River gave fermentation in Witte's peptone (*W*), but not in Poulenc peptone (*P*). Pure *colon* cultures gave fermentation in both. The difference between the peptones was not attributable to the initial difference in p_H ($W = 6.5$, $P = 5.3$), although controls showed that an initial p_H 5.0 prevented fermentation. Nor was it the end p_H which was always 4.6–4.9 with or without fermentation. It was caused by the addnl. acidity produced by streptococci which were present in the river water and which developed better in *P* than in *W*. This was already indicated by the more rapid decrease of p_H in *P* (after 6 hrs. 4.5 in *P*, 5.5 in *W*). The inhibiting action on the *B. coli* of these acid-forming streptococci was partly counteracted by gelatin-melting bacteria also present in the water provided they were sufficiently numerous. These bacteria grew in *W* only. Conclusion: Poulenc peptone should not be used for test media. MARY JACOBSEN

The biological properties of cholera-like vibriones. V. A. MASLENNIKOVA. Woronesher Senit-Bacteriol. Inst. *Centr. Bakt. Parasitenk. I Abt.* 102, 148–57(1927).—The cholera-like vibriones fall into 3 groups, acid formers, alkali formers and a chemically inactive type. They breed true to type. JOHN T. MYERS

Culturing the tubercle bacillus and the importance of culture method in diagnosis. ERICKA HERRMANN. Univ. Freiberg. *Centr. Bakt. Parasitenk. I Abt.* 102, 169–73 (1927).—The antiformin method is preferable to the H_2SO_4 method. J. T. M.

How does the Shiga bacillus ferment? The biology of Bacillus metacoli (Morgan). NIELS DUNGAL. Statens Serum Inst., Kopenhagen. *Centr. Bakt. Parasitenk, I Abt.* **102,** 218-24(1927).—The acid-forming power of 14 strains of Shiga bacilli on 26 carbohydrates was as follows: glycerol^{+} (late), erythritol^{-}, adonite^{-} dulcitol^{-}, mannitol^{-}, sorbitol^{+-}, inositol^{-}, xylose^{-}, *l*-arabinose^{-}, *d*-arabinose^{-}, rhamnose^{-}, glucose^{+}, levulose^{+}, galactose^{+}, mannose^{+}, lactose^{+-}, saccharose^{+-}, maltose^{+-}, trehalose^{+-}, raffinose^{-}, melezitose^{-}, dextrin^{-+}, inulin^{-}, starch^{-+}, amygdalin^{-}, salicin^{-}. The fermentation reactions are not quite const., but sufficiently so to distinguish between intestinal organisms. JOHN T. MYERS

The action of bile on enterococci and streptococci. WALTER LÖWENBERG. Rudolph Virchow-krankenhause in Berlin. *Centr. Bakt. Parasitenk. I Abt.* **102,** 244-5 (1927).—Enterococci will multiply in human bile in the majority of cases while *Streptococcus hemolyticus* and *viridans* will usually die within 24 hrs. Na taurocholate acts in the same way. JOHN T. MYERS

Bacteriophage phenomena in the case of a water bacterium, B. cloacae Szegediensis crystalliformans. A. V. JENEY. Franz-Joseph Univ., Szeged. *Centr. Bakt. Parasitenk. I Abt.* **102,** 263-8(1927).—A bacterium was isolated from sewage-contaminated water, described and named as above. A bacteriophage was found in culture filtrates which caused lysis in liquid and in solid media. In agar plates after 3 or 4 days incubation, and before the medium dried out, crystals visible to the naked eye appeared in the lytic zone. Attempts to isolate enough of them for recrystn. were unsuccessful. It is not known whether they are org. or inorg. Enough were fished out for the detn. of crystallographic data. They belong morphologically and optically to the rhombic system, and are elongated in the direction of the vertical axis. There are 2 vertical axes with an angle of about 8 to 10°. The index of refraction is slightly greater than that of Jena glass. Double refraction is weak. The color is grayish white, large masses appearing yellow. They often form aggregates with the longer planes in apposition, and tend toward a radial arrangement. They disintegrate in the air. JOHN T. MYERS

Endotoxins of the paratyphoid-enteritidis bacteria. LOUIS BAHR AND AAGE DYSSEGAARD. *Centr. Bakt. Parasitenk. I Abt.* **102,** 268-97(1927).—The endotoxin from 32 freshly isolated strains was studied. Animals were inoculated intraperitoneally and by mouth. The toxins were strongest in 9 to 16 day bouillon cultures. p_H had little effect. The no. of organisms is important. Toxicity and virulence are not always parallel. JOHN T. MYERS

A method of selective enrichment for paratyphoid in water and feces. FRIEDRICH HODER. Univ. Prague. *Centr. Bakt. Parasitenk. I Abt.* **102,** 313-9(1927).—The addn. of malachite green (between 1:5000 and 1:10,000) to a medium consisting of 10% bile in bouillon favors the growth of paratyphoid bacilli. JOHN T. MYERS

Coagulation of egg yolk by cholera and cholera-like organisms, and consideration of the resulting products. V. S. DERKACH AND B. BRECHER. Bact. Inst., zu Charkow. *Centr. Bakt. Parasitenk. I Abt.* **102,** 319-26(1927); cf. *C. A.* **22,** 1173.—Sp. cholera always coagulates egg yolk, but many of the cholera-like organisms do not. Egg yolk and milk coagulation are not always parallel. JOHN T. MYERS

Lytic enzymes in the pseudobacteriophagy of anthrax. GYULA DE DARÁNYI. Tierärtzlichen Hochschule Budapest *Centr. Bakt. Parasitenk. I Abt.* **102,** 326-9(1927). JOHN T. MYERS

Studies on the biological properties of Besredka filtrates. I. Inhibiting factors in filtrates of bouillon bacterial cultures. G. S. BARG. Bact. Inst., Kiew. *Centr. Bakt. Parasitenk. I Abt.* **102,** 398-406(1927).—Staphylococcus filtrates had an equally bad effect on homologous and heterologous strains of staphylococci. Streptcoccus filtrates inhibited heterologous as well as homologous strains of streptococci. Staphylococci will grow in streptococcus filtrates but streptococci will not grow in staphylococcus filtrates. JOHN T. MYERS

The action of fatty acids and their products on the morphology and staining reactions of bacteria. DEMETRIOS PETROCHILOS. Univ. Heidelberg. *Centr. Bakt. Parasitenk. I Abt.* 102, 471-7(1927).—Fatty acids exert an inhibiting action on various bacteria. This effect gradually decreases from the lower to the higher members of the series. Fatty acid products with a moderate no. of C atoms have a still greater inhibiting action. JOHN T. MYERS

The decolorizing properties of Chinese India ink in bacteriological technic. GUSTAV HOCHMILLER. Tierärtzlichen Hochschule, Wien. *Centr. Bakt. Parasitenk. I Abt.* **102,** 478-84(1927).—India ink has a definite decolorizing action on bacteria stained

with basic aniline dyes. When stained with aq. dyes, decolorization is complete. Tubercle bacilli are only slightly decolorized by the following technic, but non-pathogenic acid-fast bacteria are completely decolorized. Stain by the Ziehl-Neelsen method, omitting the acid alc. · Place a drop of ink at the edge of the smear and draw it over with a slide exerting some pressure and dry after 20 sec.: or cover with ink and heat for a few sec. over a flame: or shake in a container of ink for several seconds. Gram-negative organisms are much more readily decolorized than Gram-positive ones.
JOHN T. MYERS

The cultivation of the tubercle bacillus in negative sputum. IGNAZ SCHILLER. Reichslaboratorium Chem. Bact. and Laboratorium des Roten Kreutzes. Odessa. *Centr. Bakt. Parasitenk. I Abt.* **108**, 1-7(1928).—The following medium is used for the treatment of sputum which is neg. for tubercle bacilli on direct examn.: glycerol 75 cc., distd. water 25 cc., and glucose 2 to 5 g. It need not be sterilized. Equal vols. of sputum and the medium are mixed and incubated for 24 hrs. at 37°. Smears prepd. as usual must be washed with boiling water after flame fixation, to remove all traces of glycerol which interfere with the Ziehl-Neelsen staining technic. In sterile tissue bacteriolysis of tubercle bacilli occurs quickly. When pieces of sterile guinea pig tissue finely minced are added to this medium (2 lungs or 1 liver to 100 cc.), growth occurs rapidly, reaching a max. in 9 days. Ordinary media contg. the percentage of glycerol in this medium will not permit growth. In hydrolyzed sputum, the tubercle bacilli often disappear. If placed in the glycerol reagent for 24 hrs. rods again appear. They may have gone into the filterable state which some investigators have reported. Such hydrolyzed sputum will not infect animals. JOHN T MYERS

A study of the virus of poliomyelitis, encephalitis and herpes. M. GERBASIS AND M. GUIFFRÈ. Universitätskinderklinik zu Palermo. *Centr. Bakt. Parasitenk. I Abt.* **108**, 58-87(1928).—It is possible to cultivate the virus of herpes simplex, of encephalitis, and of poliomyelitis in the anaerobic medium of Noguchi or of Di Cristina. Growth appears in about 1 month at 37°. In freshly isolated cultures a diffuse cloudiness appeared, but in later generations, granular material appeared along the walls of the tube, consisting of very small cocci. Complement-fixing bodies were present in the blood serum cases of herpes and of animals inoculated with an antigen made by drying herpes cultures at 40° and extg. with alc. for 7 days at 37°, the filtrate then being titrated. Blood from cases of encephalitis and of poliomyelitis after recovery contained antibodies for encephalitis but not for herpes cultures. The virus of herpes differs from that of poliomyelitis and encephalitis, the latter being closely related.
JOHN T. MYERS

Capsule substance from Bacillus avisepticus. F. HOFFENREICH. Univ. Budapest. *Centr. Bakt. Parasitenk. I Abt.* **108**, 87-9(1928).—A polysaccharide was isolated as follows. Make a heavy suspension of *B. avisepticus* in isotonic NaCl soln. from 24 hr. horse-muscle infusion agar cultures. Add sufficient KOH and KOAc to make the concn. of each 2%. Heat for 2 hrs. on the water bath. Centrifugalize and neutralize the liquid with HOAc. Add 1 third vol. of satd. U acetate and filter to remove protein. Add KOH and filter to remove U. Dissolve in HOAc. Add Na phosphate and remove the U phosphate ppt. with the centrifuge. The yellowish liquid obtained gives the brown color reaction of glycogen with Lugol's soln. It reduces Fehling's and Benedict's soln. It contains only a trace of N. To some of the liquid an equal vol. of abs. alc. was added. After 24 hrs it was filtered and the residue washed with a mixt. of 2 parts abs. alc. and 1 part ether and dried in a desiccator. With a serum which agglutinated *B. avisepticus* at 1:640, a 1% aq. soln. of this substance gave a ppt. at 1:640,000. The reaction was sp. Rabbits could not be immunized with this substance.
JOHN T. MYERS

A simple plate method for cultivating obligate anaerobes (anaerobic bacilli, filterable anaerobic, bacteria, Treponema pallidum). JOSEPH FORTNER. Robert Koch Inst., Berlin. *Centr. Bakt. Parasitenk. I Abt.* **108**, 155-9(1928).—*Treponema pallidum* will produce surface colonies on rabbit blood agar without glucose in ordinary Petri dishes, if $^1/_3$ of the plate is inoculated with *B. prodigiosus* to remove O and the dish sealed with "plastilin." *Bact. pneumosintes, B. tetani, botulinus, histolyticus, putrificus verrucosus, sporogenes* and *Amylobacter* were grown in a similar manner on sheep blood agar with glucose. *B. coli* could be used instead of *B. prodigiosus*, but *B. proteus* was not so good.
JOHN T. MYERS

The conservation of bacterial cultures with paraffin. GYULA DE DARÁNYI. Univ. Budapest. *Centr. Bakt. Parasitenk. I Abt.* **108**, 160-2(1928).—The surface of a slanted medium is dried at 45° and inoculated. When growth appears, the tube is filled with paraffin about 1 cm. above the top of the slope. Fragile organisms like streptococci

remain viable several months. More resistant ones like *B. pyocyaneus* live for 1.5 years.
JOHN T. MYERS

The differentiation of virulent and avirulent strains of B. mallei by means of methylene blue reduction. B. M. GURNIVITSCH. Mil. Veterinar-Bact. Lab. Nr. 1 Uvo. *Centr. Bakt. Parasitenk. I Abt.* **108**, 177-85(1928).—The rate of reduction of methylene blue by *B mallei* is in direct proportion to the no. of bacilli. Avirulent strains grow more luxuriantly; hence they reduce the blue more rapidly. The difference is more marked with 1% concn. of methylene blue in the medium than with 0.25%. Avirulent strains remain decolorized as long as a month, while virulent strains begin to show reoxidation by the air within 48 hrs. The culture medium used was 3% beef infusion broth. The addn. of 2.5% formalin to the incubated culture inhibits reduction, but toluene facilitates it. JOHN T. MYERS

The influence of carbohydrates and of hydrogen-ion concentration on the sporulation of saccharomycetes. FELIX WAGNER. Tech. Hochschule in Wien. *Centr. Bakt. Parasitenk. II Abt.* **75**, 4-24(1928).—Carbohydrates have a marked and sp. influence on sporulation of yeasts. The effect of the same carbohydrate may differ with different species. In general fermentable carbohydrates stimulate sporulation more than do non-fermentable ones. Previous growth in a medium contg. one sugar may prevent another sugar from stimulating sporulation when it is added. Glucose and beer wort have the greatest augmenting effect. The opt. percent of sugar is 10, but even traces will cause sporulation. The age of the culture when the sugar is added, up to 7 days, has no significance except in the schizosaccharomycetes, which are very sensitive. H-ion concn. limits are narrower for sporulation than for vegetable growth. Of the organisms, Tries saccharomycetes Johannesberg had the widest range, p_H 2.4 to 9.07. The percentage sporulation does not vary much within these limits. The acid range is always longer than the alk. range. Growth may continue at somewhat higher or lower p_H values. Wood blocks are a satisfactory means of preventing increase in alky., free OH ions being bound by lignin. Gypsum acts in the same way but even more rapidly. Sticks of Al_2O_3 are unsatisfactory because partly hydrolyzed. J. T. M.

Comparative studies on acid formation by Bacillus Delbrücki and the cold lactic acid bacilli (Bacterium acidi lactici and Bact. cucumeris fermentati Henneberg). STAIGER AND M. GLAUBITZ. *Centr. Bakt. Parasitenk. II Abt.* **75**, 25-8(1928).—The acid was detd. in cultures of *Bact. Delbrücki* and in mixed cultures of *B. acidi lactici* and *B. cucumeris* in the following media using 250 cc. amts. *Cucumeris* was incubated for 18 days at 45° and the others were incubated for 18 days at room temp. The results are given as cc. of *N* lactic acid. (1) represents Delbrücki and (2) the others. Saccharose 5%, yeast ext. (as a source of N); (1) 17.5, (2) 26.25%: Saccharose 10%, yeast ext. 3%; (1) 21.25%, (2) 36.25%: Dextrose 5%, yeast ext. 1.5%; (1) 8.75, (2) 23.75: Dextrose 10%, yeast ext. 3%; (1) 10.0, (2) 33.75: Maltose 5%, yeast ext. 1.5%; (1) 12.25, (2) 28.75: Maltose 10%, yeast ext. 3%; (1) 12.25, (2) 35.0: Molasses 10% (50% cane sugar with other substances which act as a source of N), yeast ext. 1.5%; (1) 28.75, (2) 45.0: Molasses 20%, yeast ext. 3%; (1) 35.75, (2) 57.5: Molasses 10%, (1) 11.25, (2) 18.75: Molasses, 20%, (1) 12.5, (2) 20.0. JOHN T. MYERS

The precipitation of iron compounds from salts of organic acids by some species of Eubacteriales. I. M. LEWIS. Univ. of Texas. *Centr. Bakt. Parasitenk. II Abt.* **75**, 45-52(1928).—The pptn. of Fe by a large no. of common species of the Eubacteriales group was studied. Standard agar was compared with the following synthetic medium: KH_2PO_4, $MgSO_4$, $NaNO_3$, NH_4NO_3, each 0.05%; $CaCl_2$, 0.02%; in distd. water 0.1% of the Fe salt was added. Various species from widely sepd. families can deposit Fe while closely related species may differ. Strains which ppt. Fe are distinguished from those which do not by their ability to use the org. radical as food. Natural waters and displaced soil solns. do not contain the opt. amt. of phosphates for bacterial pptn. of Fe from org. Fe compds. If phosphate is added pptn. becomes much more rapid. Pptn. of Fe occurs in the presence of other C comps., thus showing simultaneous utilization. The citrates, tartrates and albuminates of Fe are best for use in culture media. Because of their wide distribution in soil and water, the colon group and the green fluorescent bacteria are probably the most important forms of the true bacteria in natural Fe pptn. Fe deposition may be used as a differential test to det. either the utilization of certain org. acids, or N requirements. It affords a convenient method for differentiation in the colon of *Salmonella* and *Eberthella* groups. J. T. M.

The decomposition of fatty acid salts and carbohydrates by thermophile bacteria. C. COOLHAAS. Landwirtschaftlichen Hochschule zu Wageningen, Holland. *Centr. Bakt. Parasitenk. II Abt.* **75**, 161-70(1928).—The medium used contained NH_4Cl 1 g., KH_2PO_4 1 g., and $MgSO_4$ 0.5 g. The incubation period varied from 5 to 14 days.

Slime from stagnant water was the inoculating material. At 60° a long list of fatty acid salts were changed to methane and CO_2. The minimal temp. was 45° and the max. 69°. The organisms concerned were spore-forming slender rods different from the bacteria which cause a similar fermentation at lower temps. They cause a quant. fermentation of KOAc and KHCHO to methane, CO_2 and K_2CO_3. Saccharose goes completely to methane and CO_2, but this occurs only after the organisms in a culture increase greatly in no. Cellulose incubated with the same slime goes largely to methane and CO_2, but the compn. of the resulting gases is variable. Fallen cabbage leaves (dry matter 19 to 20%) when inoculated with slime yield much more methane at 60° than at 26°, and at 37° there is very little. At 60°, 100 g. of cabbage yields about 5.3 l. of methane in 20 days. JOHN T. MYERS

Biochemical properties of lactic acid microörganisms. II. Morphological and biochemical characteristics of Bact. caucasicum. I. A. MAKRINOV AND X. STROHBIDER. Inst. zu exper. Medizin, Leningrad. *Centr. Bakt. Parasitenk. II Abt.* **75,** 171–8(1928); cf. *C. A.* **22,** 3427.—*Bact. caucasicum* is a true lactic organism since it can ferment the mono- and disaccharides among the hexoses and mannitol among the alcs. and does not ferment starch, inulin, xylose, arabinose and gum arabic. It hydrolyzes protein, producing much lactic acid and only minimal quantities of other substances. It does not attack fats. JOHN T. MYERS

Cellulose as a source of energy for the non-symbiotic nitrogen-fixing organisms. PAULI TUORILA. Fidgen. Tech. Hochschule, Zurich. *Centr. Bakt. Parasitenk. II Abt.* **75,** 178–82(1928).—*Azotobacter* cannot use cellulose as a source of energy when in pure culture, but it may if mixed with other organisms. Probably other species assimilate cellulose, producing products which act as a source of energy for *Azotobacter.* The process is greatly facilitated by the addn. of small quantities (about 0.1%) of mannitol or glucose. JOHN T. MYERS

Observations on the physical and biological characteristics of Leptospira. I. J. KLIGLER AND M. ASHNER. Hebrew University, Jerusalem. *J. Bact.* **16,** 79–96(1928).—Spirochetes carry a pos. charge whereas the bacterial charge is neg. At p_H 9.2 they become negatively charged. In the absence of colloids (serum, peptone, etc.) the leptospiras are exceedingly sensitive to reaction and salinity. Without a serum buffer they die promptly at a p_H of 6.6 but are much less sensitive to alky. The opt. is between p_H 7.2 and 8.2. There are slight differences in the sensitiveness of different strains, due probably to differences in vigor, but the general behavior is the same. Salts are decidedly harmful. Even isotonic NaCl injures them. H_2O_2 solns. of 1:9000 kill them in a few sec. They are readily cultivable on artificial media. The best procedure for primary culture from animals is to cover the blood-free fibrin clot or sedimented red cells with Noguchi *Leptospira* medium to a depth of 1.5 to 2.0 cm. They are obligatory aerobes. Only a small proportion of the organisms will pass through a Berkefeld or Seitz filter. Centrifugation for 4 or 5 hrs. will practically free a suspension of organisms. JOHN T. MYERS

The action of iron and citrate in synthetic media for tubercle bacilli. GUILFORD B. REED AND E. RICE. Queen's Univ., Kingston, Toronto. *J. Bact.* **16,** 97–107(1928).—The addn. of about 0.056 g. of Fe per cc. in the form of chloride or sulfate to a synthetic medium (asparagin 4 g., NaCl 5 g., NaH_2PO_4 2 g., glycerol 30 g. and water 1000 cc.) over the ordinary p_H growth range of tubercle bacilli results in almost complete pptn. of the Fe. The addn. of 0.2 g. of Na citrate per cc. of medium, probably through the formation of complex ions, inhibits the pptn. of Fe. In the above synthetic medium adjusted to p_H 7.4, the addn. of the Fe produces approx. 20% more growth, and the addn. of both the Fe and the citrate about 100% more growth. In more acid and more alk. media the advantages are less conspicuous. Similar results are obtained with *B. phlei* and *B. leprae* in these media. JOHN T. MYERS

Variations of streptococci with a note on hemolysis production. M. FROBISHER, JR., AND E. R. DENNY. Johns Hopkins Univ. *J. Bact.* **16,** 109–16(1928).—Differentiation of streptococci should be based on low-power microscopic observation of deep and not of surface colonies in blood agar plates, and the use of tube hemolysin tests. The tube tests should be made by mixing 1 cc. of an 8 to 12 hr. 20% horse serum broth culture to 1 cc. of a 5% suspension of washed rabbit erythrocytes and incubating for 1 to 2 hrs. at 37° in a water bath. Genuine alpha (viridans) streptococcus surface colonies frequently produce hemolytic zones 2 to 4 mm. wide which appear to the naked eye to be beta (hemolytic) colonies. When the deep colonies of such streptococci are viewed with the low power of the microscope, they are seen to have about them within the hemolyzed zone the zone of methemoglobinized cells characteristic of the alpha type. These strains never caused hemolysis in the tube tests. A no. of such

strains have been found to lose a large part of their hemolytic powers when kept for some time under various artificial conditions. This may be due to a change in the organisms or to some obscure variation in technic. This may explain some of the reported changes of a beta to an alpha type. JOHN T. MYERS

Streptococcus studies. I. Streptococcus viridans derived from single cell strains of Streptococcus hemolyticus. FRANCIS B. GRINNELL. Harvard Univ. Medical School. *J. Bact.* **16**, 117-21(1928).—Single-cell strains of hemolytic streptococci gave rise in 2 instances to daughter strains having all the characteristics of the α-type. One such variant appeared as a few colonies on blood agar plates from the 14th subculture in normal horse-serum broth, and another in a similar way from the 21st subculture of a strain cultivated on blood agar at 40°. Such a change appeared only with certain strains, and the whole culture does not change. The α- variants remained true to type under ordinary conditions of cultivation. They showed a slight loss of virulence, and usually gave the same fermentation reactions as the β- types from which they were derived. JOHN T. MYERS

Hemolytic reactions of a pathogenic bovine strain of B. coli. MARION L. ORCUTT. Rockefeller Inst. for Medical Research, Dept. of Animal Path., Princeton, N. J. *J. Bact.* **16**, 123-34(1928).—Of 14 bovine strains of *B. coli*, one was hemolytic. One of these was studied in detail on solid and liquid media. The hemolytic agent is a product of the living culture, not an end product of growth, since both filtrates and killed cultures were non-hemolytic. The hemolytic action is greater in 4 than in 24 hour bouillon cultures, also in bouillon cultures than in agar growths suspended in isotonic NaCl soln In general the hemolytic power is proportional to the no. of living organisms, but this may be obscured by inhibiting factors, as too much peptone or unknown substances in the veal infusion, or both. Cholesterol and certain N sera are also inhibitory. Either aerobic or anaerobic incubation will produce hemolysin. p_H affected hemolytic activity only when it checked growth. The hemolytic agent is active at refrigerator temps. The low titer of cultures kept in the refrigerator is apparently due to decreased production rather than loss of activity. No hemolysin is formed in a culture fluid of NaCl soln. and glucose. The hemolytic substance seems to possess slight antigenic power, since immunization will increase or originate inhibitory power. In media which allowed the culture to form acid, an acid type of hemolysis occurred, but it differed from the other in being more diffuse on blood agar plates, by changing the color of the blood to a brownish shade, and by not being inhibited by serum. A non-hemolytic variant was obtained after long cultivation. **Effect of sera on the hemolytic reactions of a pathogenic bovine strain of B. coli.** *Ibid* 135-43.—Normal horse, cow and human sera prevented hemolysis by this strain of *B. coli*. Rabbit, guinea pig and calf sera caused little or no inhibition. This is probably due partly but not entirely to the cholesterol content of the serum, since inhibiting power is not always parallel to cholesterol content. Apparently the protein of horse and cow serum has inhibiting powers. Rabbit and horse serum have a different protein compn. which may explain differences in inhibition. The same is true for calf and cow serum. Milk will not prevent hemolysis The albumin-globulin ratio in serum may be a factor. In immune serum antibodies seem to play a part in inhibition of hemolysis. JOHN T. MYERS

Studies in the physico-chemical behavior of bacteria. ALLEN E. STEARN AND ESTHER WAGNER STEARN. *Univ. of Missouri Studies* [2], **3**, 1-84(1928).—Much of the physiol. as well as the physico-chem. behavior of bacteria can be ascribed to their amphoteric character, and the deviations from the behavior of solns. of single pure ampholytes shown by organisms are what one would expect from a system composed of more than 1 amphoteric component. Exptl. results are presented showing: (1) bacteria possess individual characteristic isoelec points and isoelec. ranges; (2) the organisms with isoelec. points at lowest p_H values retain cations most strongly, and vice versa for anions; (3) the higher the p_H of reaction the more strongly are cations retained and vice versa for anions; (4) any change affecting the isoelec. point affects also the retention of cations and anions; (5) organisms with isoelec. points at lowest p_H values are most sensitive to the toxic effect of cations; (6) any organism becomes more sensitive to the toxic action of cations as the p_H is increased; (7) any process which causes a shift in the isoelec. point of an organism alters its sensitivity to anions and cations; (8) the toxic action of many bacteriostats, notably dyes, seems to partake of the nature of an ionic equil.; this equil. can be easily shifted without altering relative quantities of bacteria and bacteriostat but upon so shifting the effect of the bacteriostat is markedly altered. Data obtained from a study of simple synthetic systems of more than 1 amphoeric component show analogous behavior to bacterial systems so far as

the analogy is experimentally carried. Expts. on flocculation by dyes, in which it is shown that basic dyes are increasingly effective as flocculating agents as the p_H is increased and acid dyes are increasingly effective as the p_H is decreased, indicate that the same fundamental mechanism is effective here as in staining and in growth inhibition. A discussion of the Gram reaction and of bacteriostasis is given. A. E. S.

D—BOTANY

THOMAS G. PHILLIPS

Dependence of the chemical composition of oil-containing plants on the climate. S. Ivanov. *Oil and Fat Industry* (Russia) **1927**, No. 5, 29–31, No. 6, 26–30; *Chem. Zentr.* **1928**, II, 1971.—The I no. is higher in northern climates than in southern. When plants are transplanted from one climate to another the oil content changes to correspond with the climate. A. A. Boehtlingk

The chemical nature of the poison in nettles. Ferdinand Flury. Univ. Würzburg. *Z. ges. exptl. Med.* **56**, 402–9(1927).—The hair of the stinging nettle contains an acid juice comprising small quantities of formic, acetic, butyric and other aromatic fatty acids in which the nettle poison is dissolved. The nettle poison is a resinous, non-aromatic, unsatd. N-free, acid substance. 0.0001 mg. will give the characteristic action on the skin. F. L. Dunn

Composition and structure of the cell wall of wood. Geo. J. Ritter. U. S. Forest Products Lab., Madison, Wis. *Ind. Eng. Chem.* **20**, 941–5(1928).—Continuing previous studies (*C. A.* **20**, 221) it is shown that lignin in woods examd. is of 2 kinds, one in the middle lamella and the other in the cell wall. Samples of sufficiently small dimensions were prepd. from pine, basswood and red alder; the 2 varieties of lignin were present in them in approx. equal amts., and the middle lamella lignin is more sol. in 95% EtOH than the cell wall lignin. When bordered pits are observed between Nicol prisms the optical effects produced are explained on the basis of the chain-like arrangement of the cellulosic material of the cell walls. When lignified and delignified wood fibers are treated with swelling agents, the fiber walls thicken both outwardly and inwardly, the general angular cross section area of lignified fibers remaining unaltered, but that of delignified fibers changing to a circular form. The cell walls are composed of several layers which can be sepd. by chem. means, *e. g.*, as by treatment with 68% H_3PO_4. Seventeen illustrations (photomicrographs) are appended. W. C. Ebaugh

Sweet corn seed studies. A. T. Erwin and E. S. Haber. Ia. Agr. Expt. Sta., *Bull.* **250**, 252–78(1928).—Sweet corn seed matures slowly and, because of its high sugar and H_2O content, is readily subject to mold invasion and damage in handling. Kiln drying at 100° F. is effective in drying seed corn of excessive H_2O content without impairment of germinating vigor. Immature sweet corn when kiln dried gave equally good germination as mature seed, though the seedlings were not as vigorous. C. R. Fellers

The relation of Bacterium vignae to the tissues of the lima bean. W. S. Beach. Penn. Agr Expt. Sta., *Bull.* **226**, 1–15(1928).—The migration of *Bacterium vignae* through the tissue of the lima bean is in the form of zoogloea. The matrix material in which the bacteria are embedded stains faintly in early stages but more deeply in later stages of growth which is mostly intercellular. The first reaction resembles plasmolysis, followed by disintegration of the plasma, the plastids and the nuclei. C. R. Fellers

Physical and chemical characteristics of expressed citrus-leaf sap and their significance. A. R. C. Haas and F. F. Halma. Univ. California. *Bot. Gaz.* **85**, 457–61 (1928).—The sap of normal mature lemon leaves is less active osmotically and contains less ash and Ca, but more Mg, than the sap of orange leaves. Benjamin Harrow

Plant coloring matters. VII. Lycopin. P. Karrer and Rose Widmer. Univ. Zürich. *Helv. Chim. Acta* **11**, 751–2(1928); cf. *C. A.* **22**, 394.—Lycopin, m. 173°, is easily reduced with a Pt oxide catalyst in ether soln. The amt. of H absorbed indicates that the formula for lycopin is $C_{40}H_{56}$. "Perhydrolycopin" [the reduction product] $b_{0.03}$ 238–40° without decompn.; it could not be crystallized. Its mol. weight 845 in $CHBr_3$, 837 in camphor and 525 in C_6H_6 indicates also the presence of 40 C atoms in the mol. A. L. Henne

Crystallized carotinoids from buttercup blossoms and hawthorns. H. H. Escher. Univ. Zürich. *Helv. Chim. Acta* **11**, 752–4(1928).—Description of two orientation essays. A minute quantity of xanthophyll has been obtained by a petroleum-ether

extraction of the blossoms of *Ranunculus*. Lycopin was obtained by extn. of hawthorn with petroleum-ether and pptn. with an EtOH-CS_2 mixt. A. L. HENNE

The solubility of phosphorus compounds contained in seeds. ZYGMUNT KOEHLER. *Roczniki Chem.* **7,** 692–706(1927); Abstr. of paper by Koehler, Minkowska and Lindenbaum, *Bull. Acad. Polon. Sci. Lettres Cl. Sci. Mathem. Nat. Ser. B,* **1926,** 707–848, 1007-39, 1041–98.—HCl, 0.1–1%, is most suitable for the extn. of P compds. from seeds. The extd. P increases rapidly with the acid concn. and somewhat with the quantity as long as the acid concn. is low, less rapidly as soon as higher concns. are reached. The inorg. P shows for very low acid concns. an increase followed by a decrease. This is attributed to the activation by lower and inhibition by higher concns. of an enzyme which splits org. P compds. Complete inhibition is effected by 0.1–0.2% HCl but not by 1% AcOH. The sol. org. P (phytin fraction) is extd. completely only by 1% HCl. At this concn. the proportion between extd. material and acid has little effect on the soly. One % AcOH does not completely extract the phytin P, since the extn. depends on the p_H of the soln. The inorg., org., total and phytin P of a no. of seeds is given in tables. For details see the numerous curves in the original. M. J.

Growing reactions produced by the change of hydrogen-ion concentration in germinating roots of Pharbitis hispida Choisy. FERD. HERČÍK. *Spisy vydancane Prirodovedeckour Fakultou Masarykovy Univ.* **1925,** No. 49, 3–20.—The rate of growth of roots of *Pharbitis hispida* Choisy when placed in solns. of different H-ion concn. was detd. When transferred from acid medium to an alk. medium the rate is always decreased except when transferred from p_H 4 to p_H 8. When transferred from alk. medium to acid medium the rate of growth is always increased except when transferred from p_H 10 to p_H 4. Within the acid range lowering the H-ion concn. increases the rate of growth until near p_H 7 where the rate decreases Within the alk. range raising the H-ion concn. decreases the rate of growth until near p_H 7 where the rate increases. H. R. KRAYBILL

Application of the Wood light in the study of plant pathology. L. PETRI. *Boll. staz. sper. ind. mat conrianti* **5,** 201–3(1927); *Chimie et industrie* **20,** 36(1928).—Comparative examn. with Wood's light of decoctions of dried leaves of a given plant can show whether the withering of these leaves was due to a natural cause or to the action of toxic gases, such as SO_2 (cf. following abstr.). A. PAPINEAU-COUTURE

Method of using the Wood light in the study of plant pathology. L. PETRI. *Boll. staz. sper. ind. mat. concianti* **5,** 283–5(1927); *Chimie et industrie* **20,** 38(1928).—The method consists in soaking very pure filter paper by capillary action with water in which the vegetable tissues were crushed, drying and examg. by Wood's light. In order to obtain equal fields so as to have comparable photograms the dilns. of the solns. and the rate of evapn. must be the same in all cases. The fields obtained with tissues killed by SO_2 and with tissues killed by boiling H_2O are not the same. The light-giving substance is probably contained in all living vegetable tissues and is not destroyed by SO_2 or by heating to 100°. If luminescence is absent, or if it is different in different prepns., it is an indication that certain tissue constituents which absorb the rays have also diffused. The photograms of green tissues are the most luminescent, but if the chlorophyll has been extd. with alc. the luminescence is greatly reduced. Dil. H_2SO_4 is apparently without action. The investigations are being continued with a view to detg. a fluoroscopic diagnosis for a few phytopathological cases. A. P.-C.

Biochemical and biophysical investigations of the effect of several important biological factors of the forest on the life and growth of forest trees. DÁNIEL FEHÉR AND ISTVAN VÁGI. *Matematik. Természettudományi Ertesitö* **43,** 539–51(Hung.), 552–60(Ger.) (1926).—A study of the biological factors which control the mass growth of a forest, including the CO_2 content of the air as related to the intensity of light and the bacterial content of the soil, the acidity of the soil and its effect on the growth of individual species, the humus and lime content of the soil, the abs. capacity of the soil for air and moisture, the soil flora with relation to its acidity, etc. The CO_2 concn. is lower near the ground than in normal air and increases up to 2 m. The light intensity in well-covered tracts is very low under the tree crowns, in general 2–15% of the normal intensity in unobstructed light. The effect of increasing the CO_2 concn. is problematical. The question of soil acidity is not so important in forestry as in agriculture. The bacterial content of the soil decreases as the acidity increases and p_H values less than 4 retard the decompn. processes which occur in the humus and consequently retard the growth of the trees. The lowest p_H values were found in well-closed middle-aged coniferous and deciduous forests, and the highest p_H values were found with poorly closed deciduous forests, particularly acacia. No immediate relationship was apparent between acidity and geological soil structure. The acidity is affected by the light

intensity as influenced by tree closure. The air and water capacity of the soil attain the minimum value with complete closure. The best results are obtained with a mixed growth of deciduous and coniferous trees. J. S. REICHERT

Potassium and sodium in marine algae. GABRIEL BERTRAND AND (MME.) M. ROSENBLATT. *Compt. rend.* **187**, 266–70(1928).—K and Na were detd. in 11 species of the more common marine algae. The ratio K/Na ranged from 0.60 to 1.22 in 4 species as collected. Washing the algae in distd. water generally increased the K/Na ratio. Of the washed samples of 11 species only 4 species contained more Na than K. It is, therefore, a mistaken tradition that *Fucus* and other marine algae contain little or no K. L. W. RIGGS

Genesis of starch in the bean. H. COLIN AND R. FRANQUET. *Compt. rend.* **187**, 309–11(1928).—In the following table $[\alpha_1]$ and $[\alpha_2]$ indicate the rotatory power of the total sugars before and after inversion, *T* the percentage of total sugar calcd. to fresh tissue, *R* reducing sugar, *S* sucrose, *St* stachyose (cf. Tanret, *C. A.* **7**, 1739) and *A* starch:

L. W. RIGGS

Excess soluble salts as the cause of vegetable diseases in greenhouses. S. D. CONNER AND C. T. GREGORY. *Proc. Indiana Acad. Sci.* **37**, 385–90(1927).—The percentages of sol. salts under thrifty lettuce in 7 greenhouses ranged from 0.10 to 0.25 at 3 in. below the surface. At 6 in. below the surface in 2 of these greenhouses the figures were 0.25 and 0.29%. Under stunted lettuce, but with no pathogenic disturbances, the percentages of sol. salts for 3 in. below the surface ranged from 0.26 to 0.97, and at 6 in. below the surface from 0.36 to 0.70. L. W. RIGGS

Hydrogen-ion studies of water, peat and soil, in relation to ecological problems at Bacon's swamp, Marion Co., Indiana. STANLEY A. CAIN. *Proc. Indiana Acad. Sci.* **37**, 395–401(1927).—In lowland forest alky. increased with the depth. Peat samples were all acid, those from the northern end being slightly acid and those from the southwest end reaching a p_H of 4.4. Soils can best be tested in the lab. because of the necessity of filtering, or better centrifuging, to give clear solns. for colorimetric readings. A series of 44 checks of the colorimetric method with the electrometric method gave an av. deviation of 0.061 p_H, showing the standard colorimetric method to be sufficiently accurate for this work. Water samples should be tested for p_H in the field, as they rapidly change in p_H because of the respiratory-photosynthetic relations of the microorganisms present in the water. Peat samples, even when extd., show very little change in p_H although allowed to stand for several days. This is evidently correlated with the relative absence of microörganisms. Different soils vary in this respect. In the hydrophytic assocns. there is a diurnal trend in p_H. The habitats are most acid in the morning and are less acid after the photosynthetic period. This trend is directly correlated with the respiratory-photosynthetic ratio. In both soil and aquatic habitats there seem to be certain p_H ranges within which the various assocns. are found. In most instances the different assocns. overlap so that little emphasis can be placed on acidity as a limiting factor in the vegetation present. L. W. RIGGS

Relation of lime to the absorption of iron by plants. WM. P. ALLYN. *Proc. Indiana Acad. Sci.* **37**, 405–9(1927).—Stalk tests indicate that the excessive use of $CaCO_3$ on soils does not render Fe unavailable for corn plant absorption. The application of lime increased the deposition of Fe at the nodes, especially where the soil had become neutral or slightly alk. The heavy deposits of Fe at the nodes of plants grown on heavily limed plots did not necessarily indicate that the total absorption of Fe was greater. The application of manure or potash decreases materially the amt. of Fe deposited at the nodes. The results of this study indicate that lime-induced chlorosis

is not a result of Fe becoming locked up in the soil, but rather the result of a disturbance in the metabolism of Fe after it had been absorbed by the plant. L. W. Riggs

Cell sap of Valonia and Halicystis. W. C. Cooper, Jr., and L. R. Blinks. Rockefeller Inst. *Science* 68, 164-5(1928).—Comparison between the saps of *Valonia ventricosa* of Florida and the Bermuda *Halicystis*, formerly known as *V. ventricosa*, showed a higher percentage of K in *V. ventricosa* than in *V. macrophysa*, while *Halicystis* contained less than $^1/_{30}$ of the K of *V. macrophysa*. L. W. Riggs

Mutations in barley induced by x-rays and radium. L. J. Stadler. *Science* 68, 186-7(1928).—Irradiation by x-rays or Ra of barley plants resulted in 48 mutations, out of 2817 head progenies, causing distinct seedling characters. These include nearly all of the seedling characters of barley already reported and several not previously described. No mutations were found in 1500 head progenies of untreated plants. L. W. Riggs

High and low frequency measurements with laminaria. L. R. Blinks. Rockefeller Inst. *Science* 68, 235(1928).—There is no change in the sp. cond. of either the inter- or intracellular material during treatment with $CaCl_2$ or NaCl, since the high frequency value remained const. The changes in impedance are not due to changes of capacitance since the latter would not affect the d. c. readings, which agree entirely with the 1000 cycle values. What capacitance there is has little effect on the impedance except at much higher frequencies. Changes in cross section may occur but are not sufficient to explain the results. The results of this study support the interpretation advanced by Osterhout that the observed resistance change is really a change in the permeability of protoplasm to ions. L. W. Riggs

Composition of the cell juices of Valonia macrophysa. Rudolf Höber and Josephine Höber. Zoöl. Station, Naples. *Arch. ges. Physiol.* (Pflüger's) 219, 260-72(1928).—Analyses of the cell juices of *Valonia macrophysa* show that *Valonia* is permeable for Cl, and probably for K also. Permeability is increased by caffeine, Ca and SO_4 entering less readily than K, the anion CN less readily than SO_4. A membrane may be impermeable to an electrolyte and still permeable to its ions. Sometimes the selective anion- and cation-permeable surface areas are both present. G. H. S.

The electrical conductivity of protoplasm. Samuel Gelfan. Univ. Calif. *Protoplasma* 4, 192-200(1928).—The sp. conductance of the protoplasm, apart from the cell membrane of *Amoeba proteus, Euplotes, Spirostomum teres, Frontonia*, of the plant cell *Nitella* and the starfish oögonia, has been detd. by means of nonpolarizable microelectrodes. The points of the electrodes were minute enough to penetrate the cells without greatly injuring them. The conds. of all these forms except the starfish eggs vary from one that is equiv. to a 0.01 *N* KCl soln. to one that is equiv. to a 0.06 *N* KCl soln. The av. is equiv. to about a 0.05 *N* KCl soln. The cond. of the starfish eggs is very high, equiv. to a 0.25 *N* KCl soln. It is pointed out that the conductance of the protoplasm is not affected by the viscosity. This and other evidence is advanced, pointing to a micellar structure of protoplasm. M. H. Soule

The effect of hydrogen-ion concentration upon the fixation image of various salts of chromium. Conway Zirkle. Bussey Inst., Harvard Univ. *Protoplasma* 4, 201-27 (1928).—The root tips of *Zea mays* were left in the fixatives from 36 to 40 hrs. and were then stained in Haidenhain's iron-alum hematoxylin. *Conclusions*.—The fixation image of a dichromate depends upon the p_H at which it is used. If the soln. is more acid than a given crit. point, the image will be practically that of chromic acid, *i. e.*, in resting cells the nucleolus will be a darkly staining globule in the center of a hollow nucleus whose periphery is formed by a chromatin reticulum. No mitochondria will be preserved and the cytoplasm will be disorganized. In dividing cells, the chromosomes and spindle fibers will be well fixed. If the soln. is on the alk. side of the crit. point, the fixation image will be quite different. In the resting stage the nucleolus is fixed as in the acid fixative, but here it appears in a solid nucleus composed of fixed nuclear lymph. The chromatin and spindle fibers will be dissolved so the tissue will show no mitotic figures. The mitochondria and cytoplasm will be well fixed. The change from one fixation image to the other is as a rule sudden and complete, the point of change depending upon the dichromate used and ranging among those investigated from p_H 4.2 in the case of ammonium to about p_H 5.2 in the case of Zn. After the change has taken place, a further change in p_H has little effect upon the fixation image. With an excess of the cation present as an oxide, hydroxide or carbonate, however, certain dichromates buffer at points where the 2 fixation images overlap. Thus Cu (p_H 4.6), Be (p_H 4.6) and Ce (p_H 4.8) dichromate fix nucleoli, nuclear lymph, dividing chromatin, spindle fibers, mitochondria and cytoplasm. The dichromates of Ba, Bi, Fe, Pb, Al and Hg are too acid to give any but the acid fixation image. Hg prevents the nucleolus

from staining with Haidenhain's hematoxylin. Ammonium (p_H 4.2), Na (p_H 4.4) and K (p_H 4.4) dichromate, in the absence of free chromic acid, give only the basic fixation image. Sr (p_H 5.6), Ca (p_H 5.6), Mg (p_H 6.2) and Cd (p_H 5.6) dichromate buffer at points where their fixation image is basic. Zn (p_H 5.2) gives a basic fixation image except that greatly swollen chromosomes are fixed at metaphase. A mixt. of $Ag_2Cr_2O_7$ and $(NH_4)_2Cr_2O_7$ (p_H 3.0) gives the usual acid fixation image and in addn. mitochondria in badly disorganized cytoplasm. $Li_2Cr_2O_7$ (p_H 4.6) gives the basic fixation image in the epidermal cells and somewhat disorganizes the interior layers; and in more basic soln. gives a fixation image which is as yet unique. Chromic sulfate buffered with CuO at p_H 4.6 gives an acid fixation image; with formalin added the p_H is not changed but the image becomes basic. Slight traces of the acetate ion will shift a basic fixation image to an acid one even if the p_H is held const. Such substances as acetates, NH_4 salts and formalin, which greatly alter the fixation image when mixed with Cr compds., probably do not participate directly in chrome fixation but, because of their ability to penetrate very rapidly, actually fix the tissue before the Cr reaches the scene of action, the Cr constituents serving merely for a post-chromatization. The form of the mitochondria depends upon the cation of the dichromate fixatives as well as that of the p_H. Fixed with $(NH_4)_2Cr_2O_7$ they are long slender threads occasionally forming a reticulum. $NaCr_2O_7$ and $K_2Cr_2O_7$ fix them as coarser threads and slender rods; Cu, Be and Ce as shorter, stouter rods; while with Li they fix as prolate spheroids. Zn, Cd and the alk. earths as cations tend to fix the mitochondria, especially in the region of elongation, as rods and chains of granules. $Cr_2(SO_4)_3$ and formalin fix them as slender threads. The findings are best explained by assuming that chrome fixation consists, first, of a double decompn in which the cation of the fixative unites with certain elements of the cell and the anion with others; second, followed by a reduction of part of the chromate to a chromic salt, the Cr then being combined with the tissue both as anion and cation. Chrome fixation can be considered a form of chrome tanning.

M. H. Soule

Studies in the biology of metals. I. The localization of lead by growing roots. Frederick S. Hammett. Lankenau Hosp., Philadelphia. *Protoplasma* **4**, 183–6 (1928).—White onion sets (*Allium cepa*), marrowfat beans (*Phaseolus vulgaris*) and field corn (*Zea mays*) were germinated in sterilized sphagnum moss to give rootlets of the desired length (*e g.*, 15–20 mm.). The plants were then transferred to perforated paraffin disks suspended in 250-cc. beakers of H_2O contg. approx. 0.05 g. of $Pb(NO_3)_2$. The Pb was absorbed by the actively growing roots and localized by deposition in the regions of growth by cell division. The deposit was some compd. of Pb. **II. The retardative influence of lead on root growth.** *Ibid* 187–91.—The Pb ion in concns. from 10^{-6} to 5×10^{-4} retards the root growth of seedlings. M. H. Soule

Electrical potential of plant tissue and single cells. J. Gicklhorn and Karl Umrath. German Univ., Prague. *Protoplasma* **4**, 228–58(1928).—A potentiometer system with microelectrodes is described. The app. was used to det. the potentials of the various tissues of *Hedira helix* and *Primula obconica*. The single cell *Amoeba terricola* was also investigated. M. H. Soule

Factors affecting the composition of dates. M. T. Fattah and W. V. Cruess. Fruit Products Lab., Univ. of California. *Plant Physiology* **2**, 349–55(1927); cf. *C. A.* 6, 519.—Analyses were made of Mesopotamia and California grown dates to ascertain the effect upon their compn. due to differences in variety and of the locality where grown, and also to det. chem. changes taking place during the ripening process. Owing probably to more favorable temps. during ripening, dates from Mesopotamia were higher in total sugars and lower in moisture than the same varieties grown in California. Different varieties exhibited marked differences in total sugar content, which in many cases could be attributed to arrested ripening by drying on the tree ("mummification"). The Deglet Noor variety was consistently high in sucrose; but most other varieties were low in this constituent when ripe. All unripe samples of all varieties examd. contained considerable sucrose; this decreased greatly during ripening except in the Deglet Noor variety. Sol. tannin decreased markedly during ripening under various exptl. conditions, such as incubation, dehydration, and during storage in various gases and vapors. Dehydration at 120° F. was the most satisfactory means of artificial ripening. Walter Thomas

The effect of ethylene on the respiration of bananas during ripening. L. O. Regeimbal, G. A. Vacha and R. B. Harvey. Univ. of Minn. *Plant Physiology* **2**, 357–9 (1927).—The fruit was placed in sealed glass vessels provided with inlet and exit tubes. Suitable wash bottles were inserted to free the incoming air from CO_2 and to keep the air satd. with vapor. The rate of CO_2 production was measured by means of a cond.

cell (*C. A.* 21, 3642) and the whole train of app. was kept in a const. temp. bath at 25°. The ethylene supplied in doses of 1:1000 of air by vol. was allowed to act for 15–20 min. and then aspiration was resumed. Cond. readings were taken every 15–30 min. for a period of 2 hrs. In all cases the rate of respiration trebled within a few min. and then fell off to a value lower than normal. This is attributed either to the increase of oxidation or to increase in the permeability of membranes, which would permit of the diffusion of the CO_2 already present in the cells. The stimulation wears off in less than 1 hr. The treated bananas have $^1/_5$ to $^1/_4$ more sugar than the untreated bananas, the starch content being proportionally decreased. The activity of the diastatic enzymes as well as the respiratory enzymes is increased by the treatments. W. T.

Pectin substances (SMOLENSKI, WLOSTOWSKA) 10.

HAAS, P., AND HILL, T. G.: **An Introduction to the Chemistry of Plant Products. Vol. I. On the Nature and Significance of the Commoner Organic Compounds of Plants.** 4th ed. London: Longmans, Green & Co. 530 pp. 18s.

E—NUTRITION

PHILIP B. HAWK

Vitamin-A deficiency and calcification of kidney epithelium. E. C. VAN LEERSUM. Nederlandsch Inst., Volksvoeding, Amsterdam. *Nederland. Tijdschr. Geneeskunde* 72, I, 3027–9(1928); cf. *C. A.* 22, 2187.—Rats fed on a diet deficient in vitamin A show a calcification of kidney epithelium. R. BEUTNER

The treatment of rickets with irradiated ergosterol (vitamin D.) J. C. SCHIPPERS. *Nederland. Tijdschr. Geneeskunde* 72, I, 3898–903(1928).—Favorable case reports in 16 cases. R. BEUTNER

Food value of the potato for white rats. A. GALAMINI. *Atti accad. Lincei* [6], 7, 684–9(1928).—The highly discordant results in the literature on the food value of the potato led to the present expts., in which white rats were fed only raw and cooked potatoes with NaCl added. The results show that even when eaten in large quantities potato is not a sufficient food either for the growth or for the maintenance of life of white rats. Growing rats died after having lost 27–9% of their wt. The loss of wt. was more rapid with raw potato than with cooked potato. A diet of raw or cooked potato for a long period resulted in alk. urine and other physiol. changes. Cooked potato increased the resistance to broncho-pulmonary diseases less than an adequate diet. C. C. DAVIS

Method of assay of the antirachitic vitamin D. KATHARINE H. COWARD. *Quart. J. Pharm.* 1, 27–33(1928).—A prepn. of irradiated ergosterol has been adopted by the Pharm. Soc. as a standard for the assay of the antirachitic vitamin. Its potency is such that a daily dose of not more than 0.0001 mg. will produce complete healing of rickets induced in rats under conditions described. It is proposed to define the unit of antirachitic potency as the amt. of activity contained in 0.0001 mg. of the standard. Details of a method of assay of any substance in terms of this standard are given. W. O. E.

The importance of vitamin A and vitamin C in the ration of swine concerning especially their effect on growth and reproduction. J. S. HUGHES, C. E. AUBEL AND H. F. LEINHARDT. Kan. Agr. Expt. Sta., *Tech. Bull.* 23, 1–48(1928).—The lack of vitamin A in the diet of pigs resulted in a degeneration of the nervous system, characterized in the advanced stages by striking nervous symptoms such as impaired vision, extreme incoördination and spasms. Histological examn. of the nerves so affected showed definite degeneration of the nerve bundles in the spinal cord, optic, sciatic and femoral nerves. Eye lesions are of minor importance in extreme avitaminosis A in swine. Gilts with avitaminosis A showed irregularity in the estrus cycle; it was usually more frequent and was of longer duration. Gilts bred prior to the onset of the nervous symptoms either aborted or farrowed dead pigs. Swine do not need vitamin C in their feed for growth or reproduction. The bibliography consists of 15 references. There are 20 carefully selected photographs and figures. C. R. F.

Antirachitic values of cod-liver oil, cod-liver meal and fish meal. H. O. STUART. N. H. Agr. Expt. Sta., *Circ.* 28 (1928).—With chickens as exptl. animals, vitamin D potency was detd. in these materials. In conjunction with the ration used 5% of fish meal prevented the development of rickets. Cod-liver oil and meal were approx. equal in relation to growth. The group having the highest feed consumption per individual produced the greatest gain. C. R. FELLERS

Polyneuritis in rats following shortage of vitamin B. ARTHUR SCHEUNERT AND

WOLFGANG LINDNER. *Krankheitsforsch.* **4**, 389–96(1927).—Observations upon white rats show that with very small quantities of vitamin B in the diet, just sufficient to provide for life, symptoms analogous to polyneuritis gallinarium are produced. This occurs only after long continued lack of vitamin B. P. Y. JACKSON

New pellagra-like deficiency symptoms in rats kept upon a vitamin-B-poor diet. ARTHUR SCHEUNERT AND WOLFGANG LINDNER. *Krankheitsforsch.* **5**, 268–72(1927).—The addn. of less than 30% wheat flour (60% milled) to a diet otherwise free of vitamin B caused after 50 days severe pellagra-like symptoms in white rats, especially in the extremities. With 40%, or 2 g., of wheat flour daily the animals remained normal. When fed upon a 94% milled flour the animals showed no symptoms of the disease. Less tendency to the disease was noted when increasing amts. of the outer part of the grain were fed. The addn. of 0.5 g. dry oats to the diet on two successive days was sufficient to halt the severest symptoms; and after a short time the addn. of this amt. of oats led to complete recovery. P. Y. JACKSON

Vitamin-B content of avocados. LEROY S. WEATHERBY AND EUGENE W. WATERMAN. Univ. So. Cal. *Ind. Eng. Chem.* **20**, 968–70(1928).—The vitamin B content was detd. through feeding expts. with albino rats. The pulp of fresh food was compared with Fleischmann's dry yeast as standard. The fresh pulp contained approx. $^1/_{12}$ the vitamin value of the dry yeast and apparently ranks high as a source of vitamin B. Both the antineuritic and growth-promoting factors are present. J. A. KENNEDY

Nutritive value of alba blood as a source of protein. SIGFRED M. HAUGE. Purdue Univ., Lafayette, Ind. *J. Assocn. Official Agr. Chem* **11**, 398–403(1928).—Alba blood is prepd. from spent printers' rolls (which are made from glycerol and gelatin) by eliminating as much glycerol as possible, dissolving the residue in H_2O and then drying. The product, which is used to increase the protein (N × 6.25) content of tankages, was tested for its biological value. It was found to be inadequate, both as the sole source of protein in the diet and as a supplement to corn. The addn. of a non-supplementing protein to the diet appears to have a repressing effect on growth, and the results indicate that alba blood should not be used to increase the protein content of tankage and meat by-products. A. PAPINEAU-COUTURE

Gelatin added to the diet of artificially fed infants. J. H. HESS AND I. MCK. CHAMBERLAIN. *J. Am. Med. Assocn.* **89**, 1423–6(1927); *Expt. Sta. Record* **58**, 292.—All feedings were made with fresh cow milk, approx. 2 oz. per lb. of body wt. per day, boiled water to make the total fluid intake 2.5 to 3.0 oz. and sucrose in amts. about 0.1 oz. per lb. of body wt. The mixts. were boiled 3 min. and given in 5 or 6 feedings daily. Cod-liver oil and orange juice were given daily. After a period of adjustment to this ration, the following changes were made: (1) Gelatin was added in amt. equiv. to 1% of the milk. (2) Raw egg yolk was added in amt. equiv. to the caloric value of the gelatin. Three of the infants received the gelatin-milk mixt. and 3 the egg yolk-milk mixt. during an exptl. period of 11 to 16 weeks; the 28 remaining infants received the 2 diets in alternating periods of 3 or 4 weeks each. No conclusions are drawn concerning the relative merits of the 2 types of feeding, but the figures appear to favor the egg yolk-milk mixt. L. W. RIGGS

The antirachitic activation of materials by ultra-violet rays. KÁROLY WALTNER. *Magyar Orvosi Arch.* **29**, 151–4(1928).—The results obtained with tyrosine are attributed to the presence of ergosterol as an impurity. Synthetic tyrosine cannot be activated. Vigantol (activated ergosterol) has a pronounced growth-producing influence on animals kept on diets low in Ca, and increases the serum Ca of the animals. L. W. RIGGS

Vitamin B terminology. R. ADAMS DUTCHER, *et al.* *Science* **68**, 206–9(1928).—The proposals for vitamin-B nomenclature, which have been received by the committee of the Am. Soc. Biol. Chem., are discussed in this paper. The final report of the committee awaits further study. L. W. RIGGS

Regulating the storage of vitamin A in animals that are to be used for the determination of this vitamin. E. M. NELSON. U. S. Dept. Agr. *Science* **68**, 212(1928).—Stock rats were bred when kept on a diet rich in vitamin A. Pregnant females were segregated. Litters of 6 animals were used and the no. of rats in a litter was reduced when necessary. Mothers were put on a diet free from vitamin A, some the day the young were born and others when the young were 5, 10, 15, 16, 17, 18, 19 and 20 days old. When the young had attained a wt. of 40 to 45 g. they were weaned and put on a diet lacking vitamin A. If the mother is deprived of vitamin A when the young are 16 to 18 days of age and weigh not less than 27 nor more than 30 g., and the young are weaned when they weigh from 40 to 45 g., the onset of symptoms of vitamin-A deficiency in the young seems to be independent of the amt. of vitamin A given the mother during the entire period of lactation, provided a certain min. level is not reached.

On such a ration, the exptl. animals have shown symptoms of vitamin-A starvation between the 5th and 6th week after weaning. Ophthalmia from vitamin-A deficiency seems to occur with the greatest degree of regularity in rapidly growing animals, and animals do not grow rapidly if the mother is put on a diet without vitamin A before the young are 15 days old. Onset of ophthalmia in rats deprived of vitamin A at the age of 19 days was slower than at an earlier age. Rats that weighed much more than 30 g. would eat the stock diet. L. W. RIGGS

Effect of ethylene upon the vitamin B content of celery. M. F. BABB. Univ. of Maine. *Science* **68**, 231(1928).—Expts. in feeding young rats with ethylene-blanched celery proved that the treatment of celery by C_2H_4 did not affect its vitamin B content. L. W. RIGGS

Tissue respiration of the liver during avitaminosis B. EISHICHIRO TSUKAMOTO. *Tohoku J. Exptl. Med.* **11**, 142–5(1928); cf. *C. A.* **20**, 2699.—Pigeons fed a diet of polished rice showed a decided fall in the O consumption of the liver. In the case of fasting pigeons the O consumption of the liver in cc. per g. per hr. was the same as in normal pigeons. L. W. RIGGS

The nutritive value of bread, with special reference to its content in vitamin B. W. CRAMER AND J. C. MOTTRAM. *Lancet* **1927**, II, 1090–4.—Confirming other observers, it was found that wheat germ is very rich in vitamin B and at least equal in potency to yeast. The various milling products of the wheat grain contain vitamin B in the following proportions: germ 100, middlings 50, bran 33, patent flour 0. The vitamin B content of different kinds of bread depends upon the milling products used in the making of the bread. Thus whole-meal bread and germ bread are very rich, while white bread made with yeast is poor in vitamin B. F. B. SEIBERT

Regulation of metabolism. X. Glycogen in fatty tissues and the possible transformation of fat into carbohydrate. ERNST WERTHEIMER. Univ. Halle a. S. *Arch. ges. Physiol.* (Pflüger's) **219**, 190–201(1928); cf. *C. A.* **21**, 2298.—With rats, first deprived of food and then abundantly fed, glycogen in considerable amts. (up to 2%) appears in the fatty tissues. Glycogen is also present in the fat of frogs in Oct. and Nov., and it persists even though they are starved or subjected to strychnine poisoning. There are many reasons for holding the view that fat can be transformed into carbohydrate. G. H. SMITH

Avitaminosis and the digestive organs. HENRY E. NEVER. Univ. Hamburg. *Arch. ges. Physiol.* (Pflüger's) **219**, 554–63(1928).—The secretory activity and acidity of the gastric juice are not abnormal in avitaminosis, but as the avitaminosis progresses the activity of the pepsin increases and the digestive glands tend to accumulate pepsin and trypsin or their precursors. There is a disturbance in absorption, and secretion, motility and appetite are but secondarily disturbed. G. H. SMITH

Exclusive milk and gelatinated milk diets. ANDREW NEFF. *Med. J. Record.* **128**, 67–8(1928).—The majority of 9 subjects drank milk, plain or gelatinated, for 1 month. This constituted their whole diet except for 0.5 g. fruit, which was taken daily. Each subject drank about 4 qts. milk per day. No definite advantage of either milk was observed, although the gelatinated milk was less constipating and had a higher food value because of the added protein. A positive N balance was found in all subjects following this routine, and their wts. increased or remained const. R. C. W.

Dietetic investigations of edible pure cellulose. J. W. FREY, E. R. HARDING AND T. R. HELMBOLD. Mellon Inst. *Med. J. Record* **127**, 585–9(1928).—Rats were selected as the exptl. animals because, being omnivorous, their diet is closer to that of man than other animals, as rabbits and guinea pigs, which normally live on a high-roughage diet. A basal diet of rolled oats 42, cracked corn 25, meat scrap 16, whole milk powder 12 and oil mixt. (salad oil 95%, cod-liver oil 5%) 5, was used. Small portions of liver and cabbage were given regularly to insure an adequate vitamin supply. The basal diet was decreased and cellulose prepns. were supplied to replace it. These preparations included, rice cellulose, cotton linters cellulose, diabetic flour, cellulosic rice flakes, bran cereal and agar-agar. The test was continued for three months, during which time all the animals showed splendid growth curves, in some cases better than the controls (100% basal diet). The amts. of cellulose substituted in the basal diet varied from 0.25 to 25%. The best results were obtained in the group in which 0.25% was used. Pathological examns. of the gastrointestinal tracts of the animals at the end of the test showed that pure cellulose in its preferred form is nonirritating and entirely harmless. R. C. WILSON

Decrease of resistance as a result of vitamin-D deficiency. W. EICHOLZ AND H. KREITMAIR. Chem. Lab. Fabrik E. Merck, Darmstadt, Germany. *Münch. med. Wochschr.* **75**, 79–81(1928).—Healthy full-grown rats (48) were placed on the Pappen-

heimer and Zucker rachitogenic diet consisting of meal 80.9, egg albumin 10.0, butter 5.0 and a salt mixt. which was low in P and high in Ca. The vitamin A content was enriched to prevent xerophthalmia. A daily dose of 0.0002 mg. irradiated ergosterol was given to 24 rats in addn. to the rachitogenic diet. Four weeks later 22 of the 24 rats were living, while only 4 of those on the basal diet remained. In another expt. 5 series of rats were fed on the following diets, resp.: normal diet (1), rachitogenic diet (2), this diet (2) and irradiated ergosterol (3), 2 plus yeast (4), and 2 plus ergosterol and yeast (5). The resistance, determined by the number of deaths in each series, decreased according to the diet in the following order: 5, 1 and 4 (same result), 3 and 2. It is concluded that dietetic deficiency in vitamin D effects a reduction in the natural immunity. Vitamin D plays a role as important in the maintenance or reproduction of the normal condition as that of vitamins A, B and C. Vitamin D is necessary to the growing organism for an undisturbed growth. R. C. Willson

Retention of the antiscorbutic vitamin after sterilization (Remy) 12. Oxidation of carbohydrates, fats and nitrogenous products by air in presence of sunlight (Palit, Dhar) 10.

Sansum, W. D.: **The Normal Diet.** 2nd ed., revised. St. Louis: C. V. Mosby Co. 136 pp. $1.50. Reviewed in *J. Chem. Education* **5**, 1200(1928).

F—PHYSIOLOGY

E. K. MARSHALL, JR.

The examination of the liver function by means of tetrachlorophenolphthalein injections and the influence of this substance on the liver. L. S. Hannema. Ziekenhuis aan den Coolsingel, Rotterdam. *Nederland. Tijdschr. Geneeskunde* **72**, I, 1059–70 (1928).—A criticism of Rosenthal's liver-function test (*C. A.* **17**, 588) and a comparison of this method with the bilirubin retention. A positive result of the diazo reaction, which indicates bilirubin retention, is invariably associated with a positive Rosenthal test. Slight deviations from the normal figures in the Rosenthal test are without importance because tetrachlorophenolphthalein damages also a normal liver, as found by H. R. Beutner

On the female sexual hormone, menformone, especially on menformone as the hormone causing the growth of the mammae. E. Borchardt, E. Dingemanse, S. E. de Jongh and E. Laqueur. Pharmaco-Therap. Inst., Amsterdam. *Nederland. Tijdschr. Geneeskunde* **72**, I, 2443–57(1928).—Menformone injections in rabbits and guinea pigs (80 and 400 mice units, resp., within 15 days) stimulate the growth of all sex organs. They also stimulate the growth of mammary glands in male guinea pigs and other animals. No other substance produces such actions. Menformone, present in the blood, is the cause of proliferation of the mammae, not only in adult women, but also, *e. g.*, in newborn children, and also in pathol. cases, as *e. g.*, trophoblast. The internal parts of the mammary gland are just as well over-developed under the influence of menformone. *By continuous injections of menformone, the authors have been able to produce a regular abundant milk production from a male guinea pig.* R. B.

The female sexual hormone (menformone), especially its anti-masculine action. E. Borchardt, E. Dingemanse, S. E. de Jongh and E. Laqueur. Pharmaco-Therap. Labor. Univ. Amsterdam. *Nederland. Tijdschr. Geneeskunde* **72**, I, 2866–82(1928).—Injections of menformone check the development of the male sexual organs and also the primary and secondary sexual characteristics. This arresting disappears entirely after discontinuing the menformone injections. Even in adult animals (rats, rabbits and guinea pigs were used), a considerable decrease of the sexual organs can be obtained by injecting high doses of menformone, *viz.*, 20 to 60 mice units daily. The lowest dose which has any effect is 1 unit daily. The "all or nothing" law does not hold in this case, even low doses showing some action; the action increases with the dose. Mammae and adrenals increase in size following menformone injections. R. Beutner

The oxygen capacity of human blood and its relation to the hemoglobin content by colorimetric and spectrophotometric methods. Masataka Ohno. *Z. ges. exptl. Med.* **53**, 82–90(1926).—The O capacity of Barcroft's micro method for capillary blood in 10 healthy individuals varied between 18.19 and 21.96 cc. vol. %, the av. being 19.81%. The O capacity was proportional to the hemoglobin content, the factor being 1.324 cc. O per g. hemoglobin. The av. values for hemoglobin content per 100 cc. blood were 14.79 g. by Barcroft's O-capacity method, 15.08 by Burker's colorimetric method (*C. A.* **18**, 2354), and 14.83 by the use of the Hüfner spectrophotometer (*Z. physiol. Chem.* **1**, 317(1877)). Bibliography. F. L. Dunn

Metabolism in dogs following liver extirpation. V. M. Vesselkina. Lesshaft Institut, Leningrad. *Z. ges. exptl. Med.* **55**, 198–213(1927).—The Eck fistula was formed and the extirpation was made at one operation. The urinary excretion following the operation until the death of the animal was studied. There was a diminution in secretion of urine, which was not associated with an albuminura. The urine was more acid, the ammonia, amino acid N, uric acid and purines were increased. There was an increase in the purine metabolism though the mechanism for this increase was not clear. F. L. Dunn

Influence of the thyroid hormone on protein metabolism. L. Lichtwitz and L. Conitzer. Krankenhause Altona a. Elbe. *Z. ges. exptl. Med.* **56**, 527–34(1927).—L. and C. studied the effect of thyroidin on the protein metabolism of a case of myxedema. Thyroidin produced a negative N balance and the ratio of protein loss to weight loss was 2.3:100 for the entire period though this ratio was variable for shorter periods (cf. Boothby, Sandiford, Sandiford and Slosse, *C. A.* **20**, 447). The negative nitrogen balance paralleled the lowering of plasma protein. F. L. Dunn

Experimental studies with the parathyroid hormone in white mice. Heinrich Süssmann. Univ. zu Kiel. *Z. ges. exptl. Med.* **56**, 817–30(1927).—No relationship was found between the toxicity of guanidine and the injection of parathyroid hormone. The blood Ca was not raised in rats on injecting parathyroid hormone. The action of strychnine and picrotoxin was not affected. F. L. Dunn

Phosphates in blood and the urinary excretion of phosphates. R. T. Brain, H. D. Kay and P. G. Marshall. London Hospital. *Biochem. J.* **22**, 628–48(1928).—In normal plasma the P is present in two forms: (*a*) the major portion, inorg., largely dialyzable, (*b*) about 10% as organically combined P. Taking phosphoric esters by mouth does not increase the concn. of ester P in the plasma; but the latter can be raised temporarily by intravenous injection of phosphoric esters. In the human subject and rabbit the source of inorg. phosphate in the urine is not the org. but the inorg. P of the plasma. There appears to be a renal threshhold for phosphate excretion. There is no relationship between the amt. of urinary phosphate and the urinary vol. Benjamin Harrow

Work on the basophilic substance in youthful red corpuscles. II. The physicochemical properties of the basophilic substances in the new erythrocytes. H. Brückner. *Arch. Hyg.* **98**, 95–107(1927).—In a moist smear of the blood of a lead-poisoned guinea pig the action of the usual fixing media, such as alcs., is to dehydrate and deform the erythrocytes; those erythrocytes which contain the basophilic substance show a polychromatic flocculation with the alcs.; and a regular granular form when they are treated with the vapor of osmic acid or with powdered dyes. Temps. of 60–100° cause the basophilic substance in the moist smear to assume the polychromatic flocculated form. With lower temps. a larger proportion of the granulated form appears. The ratio of the polychromatic to the basophile-dotted erythrocytes is a function of the temp. and of the rate of evapn of the water from the cells. Air-drying is only one method for the coagulation of the basophilic substance. The polychromatic, basophile-dotted, and vital-granulated forms all consist of the same chem. substance. In the circulating blood or in the bone marrow the basophilic substance is apparently in a solvated form. The substance can be observed microscopically only as the result of changes artificially produced. P. Y. Jackson

Respiratory metabolism in infancy and in childhood. VII. Elimination of water through the skin and respiratory passages of infants. Samuel Z. Levine and James R. Wilson. Cornell Univ. Med. College and N. Y. Nursery and Child's Hospital. *Am. J. Diseases Children* **35**, 54–60(1928).—Infants, as well as children and adults, lose approx. 75% of the heat produced by their metabolic processes by radiation and conduction, and the remaining 25% by means of vaporization of water from the skin and lungs. E. R. Main

Escape of hydrocyanic acid from the blood. E. Kohn-Abrest and Lupu. *Compt. rend.* **187**, 362–4(1928).—The escape of HCN and cyanides from the organism remains imperfectly understood. Transformation of HCN to HCO_2NH_4 and to thiocyanate may account in part for the disappearance of HCN. In order to det. the part played by the normal glucose of the blood in the disappearance of HCN from the organism, hog blood which initially contained no reducing sugar was studied as follows: Four prepns. of the blood were made and each was treated with 24 mg. of HCN. Prepn. (*A*) consisted of 200 cc. of serum without glucose, (*B*) 200 cc. of serum with the addn. of 0.3 g. of glucose, (*C*) 200 cc. of blood contg. 2% of borate without glucose, and (*D*) 200 cc. of blood with 2% borate and 0.3 g. of glucose. Each of the four 200-cc. portions was divided into 25-cc. portions in stoppered tubes. Half of these tubes were allowed

to stand at 20° and the other half at 37° for several days. The HCN was detd. by distn. in the presence of H_3PO_4 and titration with $AgNO_3$. At 20° there was no loss of HCN in 2 days from (*A*), 31.0% loss from (*B*), 7.3% from (*C*) and 14.4% from (*D*). At 37° the corresponding figures were 17.2, 68.3, 7.2 and 31.3. For 7 days at 20° the losses were 0.0, 70.1, 10.8 and 21.1%, and at 37° the corresponding figures were 17.1, 88.5, 26.2 and 82.7%. These results afford a partial explanation for the absence of HCN from the blood of victims of HCN poisoning. L. W. Riggs

Regulation of insulin production. II. Effect of carbohydrates other than glucose. E. Grafe and F. Meythaler. Univ. Würzburg. *Arch. exptl. Path. Pharm.* **131,** 80-91(1928); cf. *C. A.* **22,** 251.—The hormonal action of glucose is not to be ascribed to its distinctive chem. or physico-chem. properties, since it is exhibited by all carbohydrates independently of their optical activity, provided they are reducing or yield reducing substances in the tissues. G. H. S.

Clinical significance of cholesterol in the bile and in blood serum. IV. Experimentally induced changes in the cholesterol concentration and in the p_H of fistula bile. Rudolf Stern. Univ. Breslau. *Arch. exptl. Path. Pharm.* **131,** 221-32(1928); cf. *C. A.* **21,** 448.—There is no direct relationship between the blood cholesterol and the amt. excreted in the bile. There is no reason for thinking that by administration of acid or cholesterol a coagulation of cholesterol can be evidenced to a degree adequate to cause the formation of gall stones. G. H. S.

Respiratory function of the blood at high altitudes. Hans Winterstein and Klothilde Gollwitzer-Meier. *Arch. ges. Physiol.* (Pflüger's) **219,** 202-12(1928).—At high altitudes the alkali reserve of the venous blood from the brain is lower than that of the arterial blood. The difference in p_H of the bloods is also greater than normal. G. H. S.

Effect of the circulation and of the extramural autonomic nervous system upon absorption from the intestine. I. W. Borchardt. *Arch. ges. Physiol.* (Pflüger's) **219,** 213-26(1928). G. H. S.

Is the concentration of blood pigment in the blood corpuscles constant in all animals? L. Drastich. Masarykova Univ., Brno. *Arch. ges Physiol.* (Pflüger's) **219,** 227-32 (1928); cf *C. A.* **22,** 1617.—The hemoglobin concn. is the same for the blood cells of all species (mammals) examd., the value being about 31.7 g. of hemoglobin per 100 cc. of blood. G. H. S.

Glycogen content of the stimulus-conducting system of the heart. S. Buadze and E. Wertheimer. Univ. Halle a. S. *Arch. ges. Physiol.* (Pflüger's) **219,** 233-37 (1928).—There is some 7 times as much glycogen in heart muscle as in the conduction system. The O_2 utilization is also lower than that of the muscle. G. H. S.

Point of formation and fate of urea in dogs, and the relation between urea formation and the retention of amino acid substances and of ammonia in the liver, determined by the method of angiostomy. E. S. London, N. Kochneva, A. Cholopov, T. S. Abaschidze and A. K. Alexandry. Inst. Exptl. Med., Leningrad. *Arch. ges. Physiol.* (Pflüger's) **219,** 238-45(1928).—The liver elaborates urea continuously, although during digestive periods the output is about 2$^1/_2$ times that of the intervals between gastric activity. In addn. to the removal by the kidney, the intestinal wall withdraws urea from the blood. In most of the other organs there is somewhat more urea in the venous than in the arterial blood, but with spleen and muscle this difference is extremely small. The formation of urea in the liver is not a simple transformation of definite substances into urea, but should be considered rather as a process of internal secretion. Certain of the amino acids, such as arginine and tyrosine, seem to inhibit urea formation, cystine increases it little, if any, and alanine and cysteine are stimulating. Peptone exerts no influence. G. H. S.

Hormone of heart activity. IX. Extracts of mammalian heart. L. Haberlandt. Univ. Innsbruck. *Arch. ges. Physiol.* (Pflüger's) **219,** 279-85(1928); cf. *C. A.* **22,** 1787-8.—Exts. of beef heart, in dilns. of 1:1000, exert an inciting, strengthening, and regulating action on both the isolated ventricle and the intact frog heart. Such exts. will lead to a weak pulsation in hearts completely arrested 2-4 days after their removal from the body. They cause vasodilatation and sensitize the ventricle to adrenaline. G. H. S.

Mechanism of the second phase of gastric secretion. I. P. Rasenkov. Inst. Exp. Med., Leningrad. *Arch. ges. Physiol.* (Pflüger's) **219,** 391-401(1928).—Blood withdrawn from an animal at the moment of max. gastric secretion (induced by various chem. stimulants) causes a gastric secretion when intravenously injected into other animals. Chem. stimulants, such as Liebig's ext., cause a more marked secretory activity in the stomach when injected into the circulation than when introduced into

the stomach. Subcutaneous injections are even more effective than intravenous. The mechanism of the second phase of gastric secretion is purely chem. G. H. S.

Origin and fate of uric acid and the absorption of nucleic acid in dogs, as determined by the method of angiostomy. S. I. RABINOVICH. Inst. Exp. Med., Lenigrad. *Arch. ges. Physiol.* (Pflüger's) **219**, 402–6(1928).—Nuclein substances enter the portal vein from the intestine as soon as the simple nucleotide complex is formed, and during the second hr. of digestion they reach a concn. of 1.3 mg % in the portal vein. This concn. gradually falls; after 3 hrs. it is 0.6 mg. %; after 4.5 hrs., 0.1 mg. %. Purines are also absorbed. The absorbed derivs. of nucleic acid become distributed to the organs, without being retained by the liver, and transformed to uric acid. During digestion the blood of all veins, both peripheral and deep, with the exception of those of the liver and kidney, contains more uric acid than does the arterial blood. The portal vein shows the greatest increase in uric acid (0.33 mg. %), while the greatest loss occurs in the veins of the liver. G. H. S.

Structure of the membrane of red blood cells. Relation between permeability and molecular volume. RUDOLF MOND AND FRIEDRICH HOFFMANN. Univ. Kiel. *Arch. ges. Physiol.* (Pflüger's) **219**, 467–80(1928).—The degree of permeability of red blood cells for non-lipoid-sol. substances parallels their mol. vol. The facts observed lead to the assumption that in the cell, protein and lipoid phases are resident on the surface in a stroma network, the protein phase possessing pores of definite size through which ions and non-lipoid-sol. substances, if not of too large a mol. vol., may pass. Probably the lipoid phase contains no pores. G. H. S.

Connection between blood-sugar content and blood-coagulation time. II. ALEXANDER PARTOS AND FRANC SVEC. *Arch. ges. Physiol.* (Pflüger's) **219**, 481–4(1928); cf. *C. A.* **22**, 2606.—The power of organ exts. to hasten coagulation persists after the protein and peptone have been removed, and is due to the creatine, creatinine, and lactic acid present. G. H. S.

Relation between the secretory and motor activity of the stomach. E. I. SINELNIKOV AND M. E. GREDIG. *Arch. ges. Physiol.* (Pflüger's) **219**, 485–99(1928).—When an intensive secretion of gastric juice is induced by false feeding the motility of the stomach is inhibited, the duration of the inhibition (av. 1$^1/_2$ hrs.) depending upon the degree of secretory activity. When the secretion of juice diminishes "acid motility" develops, and as secretion stops the "acid motility" gives place either to "hunger motility" or to a complete loss of both glandular and muscular activity. Teasing the animal with meat leads to a similar sequence of events, although the period of inhibition of gastric motility is shorter (20–30 sec.). During the periodic activity of the stomach hunger motility parallels mucous secretion An antagonism is exhibited between secretion of gastric juice and hunger motility, and "psychic" secretion of juice is also inhibitory. G. H. S.

Heat production of skeletal muscle under direct and indirect stimulation, as well as in reflex contraction. ERNST FISCHER. *Arch. ges. Physiol.* (Pflüger's) **219**, 514–53 (1928).—Thermoelec. detns. are made in frogs. G. H. S.

Effect of vagal stimulation upon the coagulation time of the blood. F. PLATTNER AND Y. KODERA. Univ. Innsbruck. *Arch. ges. Physiol.* (Pflüger's) **219**, 564–71(1928). —The coagulation time of the blood of dogs, cats and rabbits was definitely lengthened following stimulation of the vagus. Stimulation of the splanchnic shortens coagulation time. G. H. S.

Can a formation of vagus or accelerans substance of non-nervous origin be observed in the frog heart? HERMANN STEFAN. Univ. Innsbruck. *Arch. ges. Physiol.* (Pflüger's) **219**, 572–6(1928).—If the action of the vagus substance on the heart is abolished by atropine, or the effect of the accelerans substance is removed by ergotamine, the application of heat stimulates the rate just as in normal hearts. G. H. S.

Does blood and serum contain a substance protecting against the results of parathyroidectomy? Reply to Isidor Greenwald. F. BLUM. *Arch. ges. Physiol.* (Pflüger's) **219**, 577–8(1928); cf. *C. A.* **22**, 1800.—It does not. G. H. S.

Effect of thyroxine on the body and particularly upon heat regulation of mammals. EMIL ABDERHALDEN AND ERNST WERTHEIMER. Univ. Halle a. S. *Arch. ges. Physiol.* (Pflüger's) **219**, 588–608(1928).—Although dogs, rabbits, and guinea pigs promptly suffer a loss in wt. when given thyroxine, and die if repeatedly injected, rats and mice are decidedly more resistant. In all species the glycogen, particularly that of the liver, is reduced. Thyroxine is more active than 3,5-diiodotyrosine. Tadpoles and the water form of axolotl are much more susceptible to thyroxine than are frogs and the land form of axolotl. Thyroxine and 3,5-diiodotyrosine modify the effect of adrenaline

on heart muscle in exactly opposite ways, thyroxine being inhibitory. In concns. between 1:6000 and 1:10,000 thyroxine reduces for a time the amplitude of contraction of the heart without changing its rate. Rats treated with thyroxine are more sensitive than are normal rats to increased external temp., their body temp. responding promptly. With the development of a high temp. death quickly takes place and the carbohydrate reserves of the liver become exhausted. The blood sugar falls and CO_2 production is increased. Thyroxine-treated mice did not bear young as did the controls. G. H. S.

Increase in the capillary active substances of the blood after stimulation of the vagus. F. PLATTNER AND O. GALEHR. Univ. Innsbruck. *Arch. ges. Physiol.* (Pflüger's) **219,** 609–12(1928).—Stimulation of the vagus causes a reduction in the surface tension of the serum, according to Brinkman, but this could not be confirmed; hence the conclusion that the vagus substance and acetylcholine (which does not alter surface tension) are different is not necessarily valid. G. H. S.

Behavior of different organs with regard to cholesterol, fat and the lecithins, as determined by the angiostomy method in dogs. S. V. NEDSVEDSKII AND A. K. ALEXANDRII. Inst. Exp. Med. Leningrad. *Arch. ges. Physiol.* (Pflüger's) **219,** 619–25 (1928).—With the majority of organs the blood entering and leaving the organ contains the same amt. of cholesterol and fatty acids, but in the fasting animal the adrenal shows a distinctive behavior as regards cholesterol, as does the spleen for fatty acids. The adrenal excretes 8 mg. of cholesterol per 100 cc. of blood; the spleen retains about 7 mg. of fatty acids per 100 cc. of blood. During digestion the situation in both organs becomes changed, the adrenal retaining cholesterol. The kidney does not absorb fat, and while the other organs retain some fat the pancreas is most active in this respect. The arterial blood contains the same quantity of lecithin in both the fasting condition and during digestion, about 2.6 mg. per 100 cc. The venous blood of the liver contains the greatest quantity of lecithin, indicating the liver as the point of formation. The organs retain lecithin to various degrees, the intestinal wall being most active in this respect. G. H. S.

The estrum in rats and the effect upon it of ovarian extracts and bile. M. A. GSELL-BUSSE. *Arch. ges. Physiol.* (Pflüger's) **219,** 626–46(1928).—The active hormone of ovarian ext. is both lipoid- and water-sol. Na taurocholate contains an active principle which acts like an ovarian hormone. G. H. S.

Fate of acetylcholine in the blood. IV. Dependence of acetylcholine destruction upon the hydrogen-ion concentration. F. PLATTNER, O. GALEHR AND Y. KODERA. Univ. Innsbruck. *Arch. ges. Physiol.* (Pflüger's) **219,** 678–85(1928); cf. *C. A.* **22,** 3896.—As serum or blood cell suspensions become more acid the breaking down of acetylcholine becomes less rapid. **V. Influence of gum arabic and starch upon the splitting.** Y. KODERA. *Ibid* 686–93.—In human serum gum arabic and sol. starch reduce the breaking down of acetylcholine. At a given viscosity the inhibitory influence of both substances is about the same. The interference exercised by gum arabic when the acetylcholine is in a blood corpuscle suspension is less than in serum, and in cell suspensions starch fails to inhibit. G. H. S.

Formation of urine in the frog kidney. XIV. Relation of amino acids to the activity of the kidney. GIORGY WATZADSE. Univ. Kiel. *Arch. ges. Physiol.* (Pflüger's) **219,** 694–705(1928).—In the artificially perfused frog kidney the addn. of glycocoll favors perfusion and urine secretion. A lack of glycocoll is more outspoken on the arterial than on the venous system. Substances with an amino group act as does glycocoll, while other N-contg. compds. such as creatine, creatinine, lactamid, ethylamine hydrochloride, hippuric acid, etc., fail to stimulate. The vessels of the intestine, and the vessels of the liver to a less degree, are susceptible to glycocoll as are those of the kidney. G. H. S.

Biometry of calcium, inorganic phosphorus, cholesterol and lipoid phosphorus in the blood of rabbits. I. Normal rabbits from recently acquired stock. ALVIN R. HARNES. Rockefeller Inst. for Medical Research. *J. Exptl. Med.* **48,** 549–65(1928). —Detns. of Ca, inorg. P, cholesterol and lipoid P were made on a series of animals recently received from the dealer for the purpose of detg. the trends of these 4 blood constituents throughout the year with the degree of their respective variations and math. correlation. For the 80 animals examd., Ca varied from 14.5 ± 0.10 to 18.5 ± 0.39 mg. and inorg. P from 4.960 ± 0.20 to 6.820 ± 0.20 mg. per 100 cc. of blood serum. Cholesterol varied from 51.1 ± 1.18 to 83.3 ± 1.34 mg. and lecithin from 94.8 ± 1.397 to 108.3 ± 10.18 mg. per 100 cc. of whole blood. Of the 6 possible combinations in calcg. the coeff. of correlation for the trend throughout the expt., 3 stand out as of math. significance: between inorg. P and lecithin the coeff. of correlation was —0.794 ±

0.088; between Ca and cholesterol —0.887 ± 0.051 and between cholesterol and lecithin 0.560 ± 0.164. C. J. West

The effect of calcium on fertility and pregnancy. Oscar Loew. *Med. J. and Record* **127,** 35–6(1928).—White mice in the proportion of 1 male to 7 females, none of the animals having reached sexual maturity, were fed on crushed Indian corn, oats and bread which had been soaked in a Ca salt soln. in a proportion of about 0.1 g. $CaCl_2$ per kg. of animal's weight. Control animals received distd. H_2O in the same proportion on their bread. In 7 months those which had received $CaCl_2$ produced 43 litters with 262 young; those which received NaCl had 33 litters with 179 young, while the controls had 23 litters and 115 young. In another series (1 male to 8 females) those receiving $CaCl_2$ had 51 litters and 297 young while those to which KCl had been fed had only 19 litters and 93 young. This depressing effect of KCl was checked in another series. In 147 days guinea pigs (6 females to 1 male) dropped 11 litters and 33 young when fed with $CaCl_2$, 8 litters and 19 young on NaCl, 6 litters and 15 young on KCl and 6 litters and 16 young on distd. H_2O (controls). Rabbits (2:1) at the end of 163 days when fed with $CaCl_2$ had 14 litters and 66 young, while the controls dropped 10 litters with 41 young. Ca lactate has been found to be the more suitable form in which to administer Ca to man. Ca retention can be secured only by a favorable degree of blood alkalinity which Na lactate produces, so the double salt Ca-Na-lactate is the best form. R. C. Willson

Latest conception of the functions of the liver and some of the most important tests. Julius Schneyer. *Med. J. & Record* **127,** 302–6(1928).—Technic of the following tests is given in full: galactose test, Ehrlich's aldehyde test, quantitative analysis for urobilinogen and water test in liver diseases. It is concluded that the liver does not produce, but secretes bile. Bilirubin and biliverdin are produced by the Kupfer cells of the reticuloendothelial system. They are produced by the elimination of globulin and hemosiderin from hemoglobin. Urobilinogen is produced from bilirubin by the loss of 1 mol. O and gaining 1 mol. H. R. C. Willson

G—PATHOLOGY

H. GIDEON WELLS

Concentration ratio of aromatic substances between serum and urine in renal health and disease. E. Becher, S. Litzner and F. Doenecke. *Münch. med. Wochschr.* **74,** 1656–7(1927).—Normally the concn. ratio for phenols and indican between the urine and serum is greater than that for N. The ratio falls in renal insufficiency to a greater extent than does that of urea. For indican the serum value may be higher than the urine value. B. C. A.

Variation of protein in blood serum in acute infection. A. Schoch. *Schweiz. med. Wochschr.* **56,** 1017–22(1926).—In pneumonia the serum-protein at first diminishes, and is later increased. The methods of Reiss, Robertson, Nägeli and Rohrer and Kjeldahl are compared. B. C. A.

Pathogenesis of edema following acute poisoning with uranium. Paul Govaerts. *Bull. acad. roy. med. Belg.* [5], **8,** 33–45(1928); cf. *C. A.* **22,** 1386.—Rabbits are poisoned by U(1 cc. of a 0.7% soln. injected daily) and receive by mouth 100 cc. H_2O or saline soln. Serous effusions appear, particularly in those animals which have ingested saline. The serous fluid is rich in proteins, contg. even fibrinogen. The accumulation of fluid is due to diminished osmotic pressure of the blood proteins, and an increased permeability of the capillary membranes, moreover to the arresting of diuresis. R. B.

Determining the prognosis of tuberculosis by means of a physicochemical examination of the blood serum. F. L. Oudendal. Amsterdamsch Sanatorium Hoog-Laren. *Nederland. Tijdschr. Geneeskunde* **72,** I, 3429–57, 3549–63(1928).—O. disproves Naegeli's statement that the quotient of the refractory index : viscosity is detd. by the relative concn. of albumin and globulin (*Deut. Arch. klin. Med* **120**). The detn. of albumin and globulin is most accurately made by a micro-Kjeldahl app. or by the nephelometer. However, serum globulin is not increased in active tuberculosis and the detn. of the sp. viscosity according to Spiro (*Arch. exptl. path. Pharm.* **100**(1923); cf. *C. A.* **17,** 1506) affords the best method of estg. the degree of activity of the tuberculous process. R. Beutner

Serum protein picture as a guiding principle in therapeutic investigations of epilepsy. Felix Frisch. *Wiener klin. Wochschr.* **41,** 838–43(1928).—In epilepsy serum protein is about 1/5 higher than normal. The increase is usually entirely in serum albumin. Observations were made on the albumin-globulin ratio in starvation and following immunization. D. B. Dill

Swelling pressure in the blood. F. Högler, A. Thomann and K. Überrack. Kaiserin Elisabethspital, Wien. *Wiener klin. Wochschr.* **41,** 949–51(1928).—The swelling of erythrocytes in NaCl and in glucose solns. is not a function of osmotic pressure alone. Normal erythrocytes remained unchanged in vol. in 8 to 9% glucose while in many pathol. cases the so-called isotonic range was 6 to 8% and in animals, 4 to 5.5%. Yet the concn. of NaCl which produced no swelling was approx. 1.0 to 1.1% for all these bloods examd., excepting that of the fish. D. B. Dill

Physicochemical studies of pathologic blood serum. I. M. Goldberg. Univ. Baku. *Z. ges. exptl. Med.* **53,** 867–77(1927).—G. added 1 cc. of serum diluted 1:10 to 1:100 to a series of lactic acid buffers made up by adding 0.1 to 1.0 cc. of a 0.01 *N* lactic acid soln. and adding water to 1 cc. After 18 hrs. the pptn. zone was detd. With a 1:20 diln. of serum a max. pptn. was obtained between 0.3 and 0.4 cc. 0.01 *N* lactic acid. 116 pathologic cases were studied and showed deviation in max. pptn. in both directions. Immunization in rabbits did not change the zone of max. pptn. In anaphylactic shock the zone of pptn. was widened. F. L. Dunn

Experimental hyperglucemia in fever. Hans Cohn. Stadt Krankenhaus Berlin-Neukölln. *Z. ges. exptl. Med.* **53,** 878–82(1927).—In rabbits with fever produced by the injection of a killed *B. coli* culture and with β-tetrahydronaphthylamine, the peroral administration of glucose did not produce hyperglucemia. The same was observed in febrile humans beings. C. suggests that the elevated metabolism and the rapid utilization of carbohydrate prevented the hyperglucemia. F. L. Dunn

Anaphylaxis studies in man and animals. VI. The protein metabolism during anaphylaxis in rabbits and dogs. A. Schittenhelm and W. Erhardt. Medizinischen Klinik, Kiel. *Z. ges. exptl. Med.* **56,** 511–7(1927); cf. *C. A.* **20,** 3034; **22,** 2782.—No significant changes in total nitrogen, rest N, and sol. N were found in the liver, lung, spleen and intestine, of dogs and rabbits following anaphylaxis. Sensitized rabbits showed a small increase in the total N of the blood. Following anaphylaxis this decreased but the rest N increased. A study of the enzymes in the organs showed no definite changes. F. L. Dunn

Investigations with alcohol-precipitable horse-flesh albumin as precipitinogen. Ch. Schweizer. Bern Board of Health. *Mitt. Lebensm. Hyg* **17,** 263–7(1926); *Chem. Zentr.* **1928,** I, 1303.—The author produces an antiserum of a relatively low activity, but which makes the animal peculiarly sensitive to the production of a highly potent antiserum, if the animal is previously treated by injecting normal horse blood serum. Russell C. Erb

An investigation of metabolism in dystrophia adiposo-genitalis. W. Nonnenbruch. *Deut. Arch. klin. Med.* **156,** 312–20(1927).—A case of dystrophia adiposogenitalis with tumor of the hypophysis showed basal metabolism lowered by 24%. After ingestion of 200 g. meat, the metabolic rate was increased after 1–2 hrs. by only 10–12% but the max. increase, 32%, was reached only after 4 hrs. A single detn. is not sufficient to det. the true sp. dynamic effect. This observation conflicts with the assumption that the sp. dynamic action of protein is a function of the anterior lobe of the hypophysis. P. Y. Jackson

The influence of suggestion upon heat regulation in hypnosis. H. Gessler and K. Hansen. *Deut. Arch. klin. Med.* **156,** 352–9(1927).—Without hypnosis the exptl. person was first exposed to a temp. of 16–18°; an increase in O_2 consumption was noted which amounted to 10–23% above that observed at room temp. With hypnosis but with no further suggestion, a decrease in external temp. caused a somewhat smaller increase in the rate of O_2 consumption; the effect here is analogous to that of sleep. Exposure to reduced temps. and simultaneous hypnotic suggestion of warmth produced no increase in the rate of O_2 consumption, or else a very slight increase. Exposure to a temp. of 13.2°, accompanied by the hypnotic suggestion of cold, caused the rate of O_2 consumption to be increased as much as 41%; suggestion of cold, while the person was warmly covered, increased the rate 29%; the hypnotic suggestion of cold produced gooseflesh and shivering. P. Y. Jackson

Changes in human blood serum which accompany the treatment of cardiac edema. Karl Recknagel. *Deut. Arch. klin. Med.* **156,** 360–71(1927).—In all observed cases of cardiac edema normal concns. of serum protein, detd. refractometrically, and by the methods of Kjeldahl and of Robertson, were found at the beginning of the treatment. Administration of strophanthin was followed by diuresis and a decrease in protein concn. After a few days the protein concn. increased rapidly and sometimes exceeded 9.6 g. %; and then fell off again to normal values. At the same time the albumin-globulin ratio was almost const., except where there were complicating infections; and the viscosity curve in these cases resembled the curve for globulin concn. The

NaCl concn., which was normal at first, had a tendency to decrease at the beginning of the treatment; after most of the edema-liquid had been expelled through the kidneys there was in all cases a rise in NaCl concn. to abnormally high values. Apparently much NaCl was removed from the tissues by the diuresis, with the production of a hyperchloremia. P. Y. Jackson

The recognition of chylothorax. R. Schaefer. *Deut. Arch. klin. Med.* **157**, 69–75(1927).—Chem. analysis of the liquid obtained by puncture of the thorax distinguishes true chylosis, in which chyle is found, from conditions in which the liquid is milky (from fat) or opalescent (from protein). A case is described in which true chylothorax resulted from a severe fall. P. Y. Jackson

The course of variations produced in the urine by disturbance of the gastric secretions. L. Hermanns and J. Salachow. *Deut. Arch. klin. Med.* **157**, 98–107(1927).—The p_H and NH_3 of the urine were detd. in hyper-, iso-, and hypoacidity of the gastric juice; and the effect of a test meal consisting of meat, vegetables, carbohydrates, or fats. Two distinct types of variations were observed. In hyperacidity a max. p_H in the urine accompanied a min. NH_3 in 1–3 hrs. In isoacidity on the other hand a rise in NH_3 was observed with a corresponding fall in p_H. P. Y. Jackson

The lactic acid content of the blood in disease of the liver. A. Adler and H. Lange. *Deut. Arch. klin. Med.* **157**, 129–42(1927).—In acute atrophy of the liver the lactic acid content of the blood varied between 40 and 90 mg. % as compared with a normal 7–13 mg. %; the concn. of lactic acid is higher with increasing severity of the condition. In cirrhosis of the liver and in hemolytic icterus there was a smaller increase in the concn. of lactic acid. Usually the higher concn. of lactic acid was accompanied by a decrease in the cholesterol of the blood. For the differential diagnosis of mech. and nonmech. icterus, an increase in lactic acid indicates the decompn. of liver cells. Following the injection into the blood of Na lactate, the concn. of lactic acid falls more slowly in those cases where the liver is diseased. P. Y. Jackson

The detection of homogentisinic acid in the serum of an alcaptonuric subject. G. Katsch and E. Metz. *Deut. Arch. klin. Med.* **157**, 143–57(1927).—The usual tests for homogentisinic acid in the urine are not delicate enough to detect certainly the smaller concn. in the serum. The following colorimetric method is recommended: 10 cc. clear serum is acidified with 1 cc. 25% H_2SO_4. The homogentisinic acid is thus liberated from its salts or other forms of combination, and is repeatedly extd. with ether. After evapn. of the ether the residue is taken up with water and filtered. The clear filtrate is brought to exactly 4 cc.; this soln. and a standard soln. of homogentisinic acid are both treated with 0.2 cc. arsenophosphotungstic acid and 0.8 cc. cold satd. borax; and after 5 min. the solns. are compared in a colorimeter. The test can be used for concns. of homogentisinic acid as small as 0.1 mg. %. It gave negative results with the serum of 16 non-alcaptonuric persons. In these patients the intravenous injection of 0.5 g. homogentisinic acid was followed by the disappearance of the acid within 30–60 min.; 3–30% of the acid was found in the urine. A similar injection into the blood of an alcaptonuric patient was followed within 40 min. by the quant. elimination of the acid in the urine. P. Y. Jackson

Metabolic investigations during the incubation period in febrile and afebrile infections. Fr. Strieck and H. E. Ch Wilson-Glasgow. *Deut. Arch. klin. Med.* **157**, 173–85(1927).—In artificial malarial infection there is observed during the afebrile preliminary period an increase in protein and in total metabolism. This effect is apparently brought about by the stimulation of sp. centers of the central nervous system. In erysipelas and in angina without fever the increase in the basal metabolic rate was from 22.1 to 24%. P. Y. Jackson

Hypoglucemic reaction following a glucose-function test. Thor Stenström. *Deut. Arch. klin. Med.* **157**, 216–23(1927).—A subnormal concn. of blood sugar is frequently observed after the first rise following the injection of glucose upon an empty stomach. The hypoglucemia may be accompanied by unpleasant subjective symptoms. P. Y. Jackson

The question of iodine in the investigation of goiter. W. H. Jansen and F. Robert. *Deut. Arch. klin. Med.* **157**, 224–46(1927).—The concn. of I in the blood is usually found to be lower in subjects with goiter, with or without thyreotoxic symptoms. The av. concn. was 4–5 γ % (γ = 0.000001g.), as compared with the normal 12–14 γ %. The org.-inorg. I in the blood was in the ratio 75:25. The abs. I content of the thyroid gland in goiter was raised from an av. of 3.34 mg. to 6.75 mg., though the value is lower than that for normal thyroid if expressed in percent (4.87 mg. %: 9.39 mg. %). The hypoiodemia, together with the lowered concn. of I in the thyroid, supports the idea that lack of I in the diet stimulates the abnormal growth of the thyroid gland. Where

thyreotoxic symptoms are present the relative I content of the thyroid is low, averaging about 5.4 mg. %, and is close to the value found in euthyroid goiter. In genuine Basedow's disease the abs. I content is also lower than normal, while the blood and tissue juices show sometimes a hyperiodemia (12–40 γ %). Following the administration of I the relative amt. of I in the thyroid is increased to approx. 30 mg. %; and the abs. I content to about 9 mg. At the same time the I content of the blood is increased to several times its normal value. A comparison of the concn. in the thyroid and in the blood is not alone a sufficient measure of the extent of abnormal thyroid function. The I plays an important role in the elaboration of the thyroid hormone and in its physiol. action, but its total quantity is of less importance than the type of compd. in which it occurs. P. Y. JACKSON

Changes in the blood plasma in tertiary syphilis with positive complement test. K. RECKNAGEL AND V. GAUPP. *Deut. Arch. klin. Med.* **158**, 9–15(1928).—The total protein, the albumin-globulin concns., the NaCl content and the viscosity were detd. in 45 cases, all of which gave a positive Wassermann test. The total protein varied from 6.32 to 8.86 g. %, with an av. 7.81 g. %; the albumin from 2.88 to 6.61 g. %, av. 5.15; globulin 1.41 to 4.88 g. %, av. 2.22. In 20% of the cases the globulin comprised more than 40% of the total protein. In the plasma the highest value observed was 0.54 g. %, the lowest 0.23. In more than 70% of the cases the concn. of globulin was higher than the normal av. 0.18 g. %. P. Y. JACKSON

The pathological physiology of gastric juice secretion. P. BONEM AND K. EGGERT. *Deut. Arch. klin. Med.* **158**, 136–41(1928).—There is always more Cl ion than HCl in the gastric juice, and the secretion of Cl ion does not cease in achylia of whatever origin. The concn. of Cl ion in the gastric juice is constantly about 0.35% higher than in the blood. Expts. are under way to det. whether the formation of HCl from chlorides is a catalytic action. Clinical observations are given of the total acid, free acid, N and Cl in the gastric juice in various pathological conditions of the stomach, when secretion is excited by a test meal contg. no Cl or N. P. Y. JACKSON

Investigation of the significance of the reticulo-endothelial system in water retention. OTTO DEICKE. *Deut. Arch. klin. Med.* **158**, 142–8(1928).—Intravenous injection of electrolytic collargol, after a preliminary period in which much or little water was taken, led to increased diuresis, and a typical di-phase curve for blood diln. The vol. of water excreted depended upon the amt. taken during the preliminary period. The effect of the collargol was not merely upon the kidneys, but the entire mechanism for water equil. was set into action. Alterations were observed in the rate of exchange between the blood and the tissues. P. Y. JACKSON

Disturbance in the water equilibrium in affections of the hypophysis. HELLMUT MARX. *Deut. Arch. klin. Med.* **158**, 149–72(1928).—Since affections of the hypophysis, such as tumors, affect neighboring parts of the brain, the disturbances noted in the water equil. cannot be definitely ascribed to hypo- or hyperfunction, or to cerebral changes. In tumor of the hypophysis, a strong water retention was noted, while the hemoglobin curve showed only slight and irregular dilutions of the blood. After the ingestion of water clinical observations showed not only irregularities in the water equil., but usually also in the sugar equil. P. Y. JACKSON

The more accurate diagnosis of diseases of the liver. I. Cholesterol and cholesterol esters in the blood of subjects with affections of the liver. A. ADLER AND H. LEMMEL. *Deut. Arch. klin. Med.* **158**, 173–213(1928).—In acute yellow atrophy of the liver there is usually found a subnormal concn. of cholesterol and its esters in the blood. Improvement of the condition is followed by a rise to super-normal values. In sub-chronic atrophy a high concn. of cholesterol was noted, but the concn. decreased to subnormal values as the condition became progressively worse. A decrease in cholesterol noted in acute atrophy and in hepatopathia corresponds to a degenerative decompn. of the liver tissues; and an increase then marks a regenerative stage. The change from hypo- to hyper-cholesterolemia takes place with the change from bilirubin to urobilin in the urine. In toxic icterus increased concn. of cholesterol is observed to accompany a strong bilirubinuria. In cirrhosis of the liver, normal or slightly subnormal concns. of cholesterol are found; a sharp fall in concn. accompanies an itensification of the disease. Splenomegalia did not affect the amt. of cholesterol in the blood. Hemolytic icterus showed in some cases a lower concn. of cholesterol, but normal concns. of the esters. The blood of a new-born contains normally 90–100 mg. % cholesterol; but with icterus of the new-born the cholesterol content is higher and the ester content relatively lower. In Weils' disease or septic icterus both cholesterol and its esters are found in sub-normal amts. in the serum. In all infectious conditions with icterus the cholesterol content is low. Syphilis usually increases the amt. of blood

cholesterol; but if accompanied by icterus the increase is not so great as otherwise.
P. Y. JACKSON

Comparative clinical, histological, chemical and biological studies on goiter at Munich. HANS SPATZ. *Deut. Arch. klin. Med.* **158,** 257–335(1928).—Usually a goiter contains more I than a normal thyroid; therapeutic use of I sharply increases the amt. in the goiter. In the same goiter, the biologically active parts contain a higher concn. of I than the less active. P. Y. JACKSON

Further investigation of disturbed carbohydrate metabolism in diphtheria. III. ARTHUR ELKELES AND FRANZ HEIMANN. *Deut. Arch. klin. Med.* **158,** 238–48(1928); cf. *C. A.* **22,** 3210.—In diphtheria the peroral administration of 10 or 20 g. glucose produced a sharp rise in blood sugar; as high as 300 mg. % or higher was observed. When 50 g. glucose was given the blood sugar concn. rose no higher than with smaller quantities but glucosuria set in. The post-diphtherial stage gave similar blood sugar curves. A resistance to the effect of insulin was observed in these cases; 20 units of insulin did not lower the blood sugar concn., nor affect the glucosuria. Ergotamine was not effective in all cases in decreasing the hyperglucemia. P. Y. JACKSON

Investigation of metabolism in tuberculosis. IV. Tuberculosis and chlorine metabolism. P. MÜLLER AND H. QUINCKE. *Deut. Arch. klin. Med.* **160,** 24–39(1928).—The Cl content of the skeletal muscles is 100–200% higher in tuberculosis than in the normal state. Such an increase in Cl is not found in pneumonia or in uremia. The water content of the muscles is also higher in tuberculosis but the increase is not so great as for Cl, nor is the increase in water sufficient to bring about an isotonic concn of the extra Cl. The retention of NaCl in the muscles cannot be attributed to any affection of the kidneys. In the other organs no regular variation in Cl was observed.
P. Y. JACKSON

Tuberculosis of guinea pigs and metallic poisoning. W. PAGEL. *Krankheitsforsch.* **3,** 372–98(1926).—A guinea pig infected with tuberculosis can withstand an injection of Na aurothiosulfate which would be more than sufficient to kill normal animals; histochem. and analytical detns. showed that the poison is retained in the tuberculous organism more than in the normal. After treatment with the Au, degenerative changes in the kidneys and spleen were checked. P. Y. JACKSON

Individual variations in oxygen respiration in surviving normal and inflamed tissues. G. BORGER AND H. GROLL. *Krankheitsforsch.* **3,** 443–67(1926); cf. *C. A.* **20,** 1667.—Observations were made upon the amt. of O_2 consumed by surviving ears of mice; both normal ears and ears which had been injected with various irritants, such as cantharides, pilocarpine, casein and thyroxine. Usually but not always an increased consumption of O_2 was observed after the treatment. P. Y. JACKSON

Changes in the sensitiveness of the skin after intravenous injection of definite chemical irritants, and after intravenous blood injection. E. LEHNER AND F. URBÁN. *Krankheitsforsch.* **4,** 375–80(1927).—Intracutaneous injection of various irritants produced a swollen area of skin usually of less extent than if the subject had been previously given an intravenous injection of the same or some other irritant. There were used morphine, caffeine, Na salicylate, Na silicate, Na thiosulfate, adrenaline, Na bromate, Na iodate, atophanil, krysolgan, neoarsphenamine, the subject's own blood, physiol. salt soln., and Ca chlorate soln. **Changes in the reaction of the skin after repeated action of light upon the same spot.** E. LEHNER AND F. URBÁN. *Ibid* 381–8.—Repeated exposure of a definite area of normal skin at a distance of 30 cm. for mm. to the rays of a quartz lamp produced after the first few treatments a more prompt and more intense reaction; but after about 3 treatments there was little itching and scarcely any hyperemia. At the same time the spot so treated became less sensitive to other irritants, such as the injection of morphine into the skin. Ten mins. after the exposure of the entire back of the subject to the quartz lamp the skin of the breast or the upper arm was more sensitive to the intracutaneous injection of morphine soln. This hypersensitivity persisted for only 30 min. P. Y. JACKSON

The study of inflammation. I. Gas exchange in the initial stage of inflammation. F. BRICKER AND A. TSCHARNY. *Krankheitsforsch.* **4,** 397–403(1927).—Comparisons were made between the ears of rabbits when one ear had been treated with water heated to 53°. Twenty min. after the treatment about 100 cc. less O_2 was found in the venous blood of the inflamed ear than in the other, indicating that this amt. had been taken up by the tissues. This difference was observed in spite of the more rapid flow of blood through the inflamed ear. During 4–5 hrs. the difference gradually decreased. The dry residue left by the blood was found to be the same for each ear. The CO_2 concn. in the inflamed ear was in some cases higher and in some lower than in the other ear at the same time. **II. Gas exchange in inflamed tissues in the intermediate and final**

Ibid 403–09.—Irregular results were obtained when comparison was made of O_2 consumption in the normal ears of rabbits and ears subjected for several days to irritation. As a rule a higher concn. of CO_2 was found in the venous blood of the inflamed ears. P. Y. JACKSON

Variations in the inflammatory reaction of the skin after repeated injections of various substances in the same spot. The artificial sensitization of the skin. E. LEHNER AND E. RAJKA. *Krankheitsforsch.* **5**, 57–77(1927).—Repeated intracutaneous injection of an irritating substance in the same spot produced a characteristic reaction. After 2 or 3 injections the immediate inflammation increased in intensity; but after further injections decreased. With certain irritants a secondary (later) reaction was observed in the skin after the disappearance of the primary inflammation. Tuberculin, gonavaccine, leutin, trichophyton ext., etc., were used. The intracutaneous injection of 0.05 cc. luetin into syphilitics and nonsyphilitics led in most cases to a sensitization of the skin at some distance from the point of injection; and the sensitivity was still present after several months. A general sensitization of the skin is regularly produced by extracts of microörganisms and by proteins; except for mustard oil and cignolin these irritants are of unknown constitution, but belong to the class of antigens. P. Y. JACKSON

Transmission of a mouse sarcoma by inoculation of untreated mice and of mice injected with trypan blue. G. O. E. LIGNAC AND G. A. KREUZWENDEDICH VON DEM BORNE. *Krankheitsforsch.* **5**, 113–25(1927).—Transmission of sarcoma occurred more readily into mice which had been injected with trypan blue and which retained the dye in the tissues; the tendency to infection is greatly increased by the retention of the dye. A rapidly growing sarcoma in a treated mouse could not be transmitted by the inoculation of a mouse which had not been treated with the dye; but it was easily transmitted to a treated mouse. P. Y. JACKSON

Investigations of cloudy swelling. H. GROLL. *Krankheitsforsch.* **5**, 126–49 (1927).—The extirpation of one kidney of a rabbit produced at once an increased rate of respiration in the other. After 48 hrs. hypertrophy set in, as was shown by an increase in weight, and especially by a gain in protein (residual N). Histological investigation shows that cloudy swelling always occurs in such a hypertrophied kidney or in a kidney poisoned with $HgCl_2$. Chem. analysis shows, however, that the swollen kidney does not necessarily differ from the normal in percentage content of water, solids, total N and coagulable protein. The water content may be much higher than normal, especially after $HgCl_2$ poison; the protein content may be lower than normal but the contrary is usually true in the hypertrophied kidney. Cloudy swelling was not necessarily accompanied by increased O_2 consumption; in some cases the rate was normal and in others subnormal. A cloudiness of the cells, unaccompanied by any increase in water, solid or protein content, was sometimes observed. This was noted not only in retrogressive changes, as in mercury poisoning, but sometimes in progressive changes as when a single kidney shows increased (compensatory) activity after the removal of the other. Cloudy swelling is by no means a definite term but includes many heterogeneous processes. P. Y. JACKSON

An investigation of the production in the skin of substances which increase or decrease the inflammation resulting from exposure to light, from irritation by light, and from urticaria factitia. L. TÖRÖK, E. LEHNER AND F. URBÁN. *Krankheitsforsch.* **5**, 293–307(1927).—With one arm of the subject tightly ligatured the skin of the back was exposed to a quartz lamp at a distance of 30 cm. for 10 min. One min. after the exposure 0.05 cc. of 1% morphine soln. was injected intracutaneously in corresponding spots on each arm. The resulting swelling and hyperemic area were approx. equal. After 10 min. a similar injection caused a more pronounced swelling and a larger hyperemic area in the unligatured arm. In a similar expt. blood was taken from the cubital vein of each arm 10 min. after exposure of the back to the quartz lamp. A part of the blood was treated with Na fluoride and a part centrifuged. Injection of 0.05 cc. of the serum or of the fluoride-blood from the arm with unhindered circulation caused in a spot of skin not exposed to the illumination a much more pronounced swelling and a larger hyperemic area than did the corresponding injection of blood from the ligatured arm. The increased effect was more noticeable with the blood than with the serum; though the blood itself, and especially the oxyhemoglobin, under other conditions diminishes the swelling. After the ligatured arm was exposed to the quartz light the intracutaneous injection in the back of a sample of blood from this arm had a more pronounced effect than the injection of blood taken from the other arm. Corresponding expts. are described with urticaria factitia instead of illumination with the quartz lamp; similar results were obtained. P. Y. JACKSON

Investigation of the influence upon local serum hypersensitiveness of action upon active mesenchyme (splenectomy and vital staining). I. F. Klinge. *Krankheitsforsch.* 5, 308–28(1928).—The local anaphylactic reaction in splenectomized dogs was not different from the reaction in normal animals. The same results were obtained by similar expts. upon rabbits and rats. The intravenous injection of $^1/_2$–1 cc. china ink in rabbits and dogs did not affect the anaphylactic reaction. However, when trypan blue was used in the same way a no. of rabbits and dogs so treated were protected from the anaphylactic reaction. II. *Ibid* 458–74.—The effect of trypan blue injected intravenously is to decrease the sensitivity of the skin if the dye is given less than 48 hrs. before injection of the serum; if 10 days elapse between the 2 injections an increased allergic reaction is observed, and necrosis may follow a single injection of 2 cc. serum. Where the protective effect was observed a quant. relation was noted between the amt. of dye necessary for protection and the vol. of serum injected; but some animals retained the dye in the tissues more readily than others. Intra- and subcutaneous injection of trypan blue in rabbits and guinea pigs protected against anaphylactic inflammation only the regions where the dye was retained. Apparently a pathological irritation of the tissue contg. the dye alters the chem. nature of the living tissue so that the antigen-antibody reaction cannot take place. P. Y. Jackson

The action of normal and of specific immunity serum upon paramecia. The immunity of paramecia to both sera. Matazo Masugi. *Krankheitsforsch.* 5, 375–402 (1928).—The normal serum of the rabbit or guinea pig has an almost immediate paralytic effect upon paramecia; the paralysis disappears after 2 to 24 hrs. The effect of the serum decreases when the serum is kept and disappears within a week. The effect does not appear if the serum has been heated to 56°, and the serum is not reactivated upon addn. of the complement. The immunization of rabbits and guinea pigs with paramecia results in the formation of a sp. thermostable antibody, which has a general paralytic or fatal effect upon the paramecia. Treatment of rabbits or guinea pigs with lipoid, extd. from paramecia with ether and alc.; or with the residue left after the extg. or with paramecia previously heated to 100° for 1 hr. brought about the formation of little, if any, of the antibody. Paramecia could not be immunized against the action of the normal serum; but treatment with a 400-fold diln. of the sp. serum, and gradual increasing of the concn., results after 4 days in immunization against a 1–20 concn. of the serum. Paramecia not so immunized were paralyzed and killed by treatment with the serum in this concn. The immunity persists for several generations. The immune paramecia lose the ability to combine with sp. antibodies. Morphologically they are more nearly spherical because of the storing up of fat in the protoplasm. P. Y. Jackson

Kidney function in diabetic coma. P. van Paassen. *Nederland. Maandschr. Geneeskunde* 15, 227–65(1928).—There is evidence of renal insufficiency in diabetic coma; high blood urea, sugar and ketone bodies with comparatively low values for the urine, lowered NH_3 and acid excretion and retarded phenolsulfonephthalein excretion Some authors attribute death in spite of insulin treatment to renal insufficiency. A study of 21 cases showed that fatalities (I) and survivors (II) did not essentially differ with regard to age (circulation), initial glucemia and ketonemia, CO_2 binding capacity and NH_3 excn. Kidney examn. revealed nothing significant beyond cloudy swelling and glycogen deposition. The *blood urea* was as a rule considerably higher in I, and ran parallel with the *nonprotein N.* Insulin improved the urea excretion in II. Frequently, however, insulin caused a transient rise of blood urea even in II, apparently because it induced oliguria. Death from coma is therefore not directly attributable to renal insufficiency. Nor does *insulin* reduce the permeability of kidney tissue as was shown by the phenolsulfonephthalein test in a group of normal and diabetic subjects. Insulin causes water retention, especially in severe acidotic cases, but only in coma does this retention lead to oliguria. There is, besides the renal factor, a disturbance of water excretion of extrarenal origin which fully develops under insulin treatment since the latter brings about a sudden change in the tissues deprived of alkali. M. J.

Sedimentation velocity of the chromocytes and serum protein determinations. W. H. Oeberius-Kapteyn. *Nederland. Maandschr. Geneeskunde* 15, 320–30(1928).—A study was made of 74 cases, 50 of which were inactive, subactive and active cases of tuberculosis, 8 normal adults and 18 children with various diseases. A *globulin* content over 3.6% (normal) was always assocd. with an increased sedimentation velocity, over 15 mm./hr. (Only the 1-hr. observation gives correct and uniform results.) There is, however, no parallelism. Both phenomena were assocd. with a shifting of the neutrophiles to the left and an increase in toxic granula. All active tuberculous cases showed an increased sedimentation velocity. The latter permits differentiation

between active and inactive cases, especially in tuberculosis of the bronchial lymph glands, where the temp. is frequently normal. The literature on sedimentation velocity in tuberculosis is reviewed. MARY JACOBSEN

Serum proteins and antibodies. G. KAPSENBERG. *Nederland. Tijdschr. Hyg. Microbiol. Serol.* **3,** 71–99(1928); cf. *C. A.* **15,** 2486; **16,** 748; **18,** 2380; **19,** 1894.—The reagins and agglutinins of the Wassermann, Sachs-Georgi and true agglutinin (typhoid and paratyphoid) reactions are contained quant. in the globulin fraction of the serum and uniformly distributed over all globulins regardless of the mode of their pptn. The intensity of the reaction is proportional to the quantity of globulin. The agglutinins seem to be attached to the globulins *in vivo,* since the latter give the full reaction in soln. after the albumins have been pptd. by the method of Freund and Sternberg. Conclusions: Albumin and globulin are chemically different proteins. Herzfeld and Klinger's view of the structure of proteins is adopted according to which the protein particles are cylinders of individual mols., each of which resembles a watch spring. The globulins as differentiated according to their soly. in salt solns. differ from each other only with regard to the no. of mols. to a cylinder. The reagins attach themselves to the individual mols. not to the cylinders. The albumin mols. have no affinity for antibodies. The Wassermann and Sachs-Georgi reagins may be considered as true antibodies, *viz.,* antilipoids: (1) They react with serum proteins like true antibodies. (2) It is known that a serum may give a pptn. reaction besides complement deviation and it is probable that the syphilitic antibody gives both the Wassermann and the Sachs-Georgi reactions. (3) Landsteiner and Klopstock have succeeded in producing antilipoids by immunological methods. In extending Ehrlich's side-chain theory, K. assumes that an antibody has a globulinophilic and an antigenophilic group. The latter is strictly sp. in those antibodies whose antigens are not related to others, and only relatively sp. in those whose antigens are related, *e. g.,* typhoid-paratyphoid. MARY JACOBSEN

Clinical contribution to the study of diabetes insipidus. ADRIANO BOCCHINI. *Pediatria Rivista* **36,** 697–707(1928).—Report of 3 cases all of which were characterized by incoercible polyuria and ready response to pituitary ext., and are therefore classified as the renal-extrarenal type. The blood NaCl was normal or subnormal while according to Veil this type is characterized by a high NaCl. It follows that the blood NaCl alone is insufficient for a differentiation. MARY JACOBSEN

Anaricin and its vaccinating properties. P. S. SDRODOVSKII AND H. BRENN. Bact. Reichsinst, Baku. *Centr. Bakt. Parasitenk. I Abt.* **102,** 412–6(1927).—"Anaricin" can be prepd. by the Ramon HCHO method as applied to diphtheria toxin. It will immunize against ricin. JOHN T. MYERS

The immunizing power of bacterial lipoids. IV. The increased toxicity of defatted bacterial bodies. R. KAWAI. Imperial Univ. of Kyoto. *Centr. Bakt. Parasitenk. I Abt.* **102,** 423–6(1927).—Ether exts. of bacteria are not antigenic, being taken up by parenchymal cells without stimulating antibody formation. Bacterial proteins are the true antigens but lipoids aid in the process by augmenting phagocytosis, defatted organisms not being readily phagocytosed. JOHN T. MYERS

The action of formalin on endotoxin (anatoxin formation). R. PFEIFFER AND H. LUBINSKI. *Centr. Bakt. Parasitenk. I Abt.* **102,** 459–70(1927).—Endotoxin is weakened from 3 to 7 fold by 4 weeks standing at 40°, or immediately by the addn. of 0.4% HCHO, in the case of *B. typhosus,* the paratyphoids, dysentery and cholera. JOHN T. MYERS

Fatty acids and mycoides lysins. JOHANN SCHUBERT. Allgemeinen Krankenhauses Hamburg-Eppendorf. *Centr. Bakt. Parasitenk. I Abt.* **108,** 151–4(1928).—Mycoides lysin can be inactivated by from 0.75 to 1.5% of the higher fatty acids beginning with myristic, especially those which are unsatd. Erucic acid will inhibit, at a concn. of 0.5%. Lipoids must play an important role in the action of antibodies. JOHN T. MYERS

The storage and binding of iodine by Trichinella in muscle. BERNARD EUG. KALWARYJSKI. Univ. Lwów. *Centr. Bakt. Parasitenk. I Abt.* **108,** 186–92(1928).—*Trichinella* in muscle have the power of combining with and storing I. The combining power depends on the glycogen content of the parasite, and the relative stability of the I complex depends on the impermeability of the cuticle to $Na_2S_2O_3$. If the I has once been completely removed by $Na_2S_2O_3$, the parasite cannot again form a firm complex. This impermeability is apparently due to the lipoid content of the *Trichinella* body. JOHN T. MYERS

Alleged acceleration of taurocholate hemolysis by normal serum. K. C. SEN AND NRIPENDRA KUMAR SEN. Allahabad Univ., Calcutta. *J. Indian Chem. Soc.* **5,** 261–8

(1928).—It was shown by Ponder (*C. A.* **18**, 2727) that taurocholate hemolysis is accelerated if serum protein is added to a mixt. of red cells and hemolyte. The authors have worked with sheep's corpuscles in saline and isotonic sucrose, using a taurocholate concn. of 5%. The time of hemolysis being observed under varying conditions it was shown conclusively that in no case was acceleration of hemolysis due to the addn. of normal serum, and they conclude that Ponder's results may be due to some particular conditions but are not generally true. Defibrinated human corpuscles were also used to check results. Sucrose appears to have an inhibiting effect on taurocholate hemolysis of sheeps corpuscles. Normal serum inhibits hemolysis of sheeps erythrocytes by sodium taurocholate both in sucrose as well as in saline, and by oleate in sucrose. It is suggested that hemolysis of red blood corpuscles by saponin, soap or bile salts is due to a peptizing influence on some of the membrane constituents and that there is no essential difference in the mechanism of hemolysis by saponin, etc. Normal serum on hemolysis makes the membrane constituents less easily peptizable by a sensitizing action and displaces the adsorbed hemolyte from the cell surface due to its great adsorption on the surface of the stroma. D. H. POWERS

Acclimatization and ionic antagonism with sheep serum and other colloids. SATYA PRAKASH, S GHOSH AND N. R. DHAR. Univ. of Allahabad. *J. Indian. Chem. Soc.* **5**, 313–28(1928).—The authors study the phenomenon of acclimatization with concd. and dil. solns. of As_2S_3, mastic and gamboge. In all cases when the addn. of acids is spread over several days, the quantitity of electrolyte to effect coagulation is *smaller* than that required when it is added all at once, *i. e.*, it shows neg. acclimatization. This phenomenon is more marked in dil. solns. The stability of dil. sheep serum toward coagulation by univalent ions of NaOAc, K_2F_2, $(CO_2K)_2$, etc., is greater than a concd. serum. Ionic antagonism is developed when serum is coagulated by mixt. of cations such as NaCl and $Ce(NO_3)_3$, NaCl and HCl, $BaCl_2$ and HCl, $CeNO_3$ and HCl, $(CO_2K)_2$ and HCl, K_2F_2 and HCl, NaCl and $(CO_2H)_2$, K_2F_2 and Cl_2CHCO_2H and Cl_3CCO_2H and NaOAc. Sheep serum behaves in certain respects like sols of mastic, gamboge, As_2S_3 and is capable of adsorbing similarly charged ions, but it is not hydrolyzed to the same extent as the gums, Prussian blue and $CuFe_2(CN)_6$. The neg. acclimatization of sols by acids originates from the checking of hydrolysis of the sols by acids. Ionic antagonism, decrease of viscosity of sols and positive acclimatization are due to the adsorption of similarly charged ions. The abnormal diln. effect of hydrolyzable sols is due to increase in degree of hydrolysis and increase in the ratio of the adsorption of the neg. to that of the positive ion on diln. The phenomenon of neg. acclimatization will only be observed in those cases where the adsorption of the oppositely charged ions is very high and that of similarly charged ions is negligible. D. H. POWERS

Spinal urea and chlorine in the retention of these substances. P. SAVY AND H. THIERS. *Compt. rend. soc. biol.* **99**, 516–8(1928).—Clinically considered, the detn. of urea and Cl in the spinal fluid does not give sufficient evidence to judge of the retention of these substances. It requires 53 hrs. for the spinal urea to come into equil. with the blood, and a longer period is necessary for the Cl. In the presence of uremia or in conditions of hyperchloremia and hyperchloration of the tissues the spinal Cl follows the blood Cl. L. W. RIGGS

Psoriasis: blood chemistry studies: treatment. B. THRONE AND C. N. MYERS. *New York State J. Med.* **28**, 914(1928); *J. Am. Med. Assoc.* **91**, 757.—In 35 cases of psoriasis studied there was no N retention The blood of untreated patients was normal in its sugar, chlorides, urea and uric acid content. $Na_2S_2O_3$ is of great value in the treatment of cases with a high sugar and low chloride content of the blood, but is of no value in the treatment of patients whose blood does not show the so-called metallic picture. Au therapy is useless and is contraindicated in cases of high blood sugar and low blood chlorides. L. W. RIGGS

Threshold of sugar elimination in diabetes. U. SPERANZA. *Policlinico* **35**, 288 (1928); *J. Am. Med. Assoc.* **91**, 683.—Conclusions: (1) The threshold of sugar elimination by the kidney undergoes important variations in the same individual, under the influence of diverse causes. (2) The variations in threshold value are, in general, in correspondence with the variations in glucemia, but they do not run exactly parallel. (3) Of the various factors capable of affecting the relations between the threshold and glucemia values, carbohydrate restriction and insulin medication act in a diametrically opposite manner to carbohydrate administration and adrenaline medication. L. W. RIGGS

Venesection hyperglucemia in dogs. HIRSOHI TACHI. *Tohoku J. Exptl. Med.* **11**, 14–32(1928); cf. *C. A.* **22**, 2623.—In this study with female dogs the blood was withdrawn from a previously deafferented region so that almost no pain occurred. For

the production of venesection hyperglucemia about 25 g. of blood per kg. of body wt., or $^1/_4$, or more, of the blood was removed. A removal of $^1/_8$ of the total blood results in a hyperglucemia of 0.2%. Double splanchnectomy causes the development of venesection hyperglucemia to disappear or to be much reduced, unless the loss of blood is large when a moderate hyperglucemia occurs. L. W. Riggs

Edema formation. I. Edema formation by perfusion of the isolated thigh preparation, in rabbits with impaired thyroid function. Chomatsu Sato. *Tohoku J. Exptl. Med.* **11**, 33–40(1928).—The literature is cited in 38 references. Perfusion of the surviving thigh prepn. of the hyperthyroidic rabbit with Ringer soln. increased the formation of edema over that in normal animals. With athyroidic rabbits the formation of edema was less than in normal animals. **II. Edema formation during the absence of vitamin B.** *Ibid* 41–6.—Rabbits with avitaminosis B and paralyzed extremeties when perfused with Ringer soln. showed less edema formation than normal animals. In rabbits without paralyzed extremities the edema was generally greater than in normal animals. L. W. Riggs

Influence of air pressure changes on the composition of the blood. I. Respiration under excess of oxygen pressure in man. Kokichi Izumiyama. *Tohoku J. Exptl. Med.* **11**, 47–55(1928).—The O pressure of the expired air was measured by the excess pressure app. according to Tiegel, and it varied from 8 to 20 cm. of water. With 7 subjects under excess of O pressure there was a diminution in the hemoglobin, red cell count, blood sugar, NaCl, serum albumin and serum viscosity Thirty or more min. after the removal of the excess of O pressure these factors of the blood had returned to their initial or more frequently above their initial values. L. W. Riggs

Effect of hemorrhage upon the rate of liberation of adrenaline from the suprarenal gland of dogs. Shizuka Saito. *Tohoku J. Exptl. Med.* **11**, 79–115(1928).—In cava-pocket expts. on dogs under ether, removal of 0.2 of the total blood caused a small increase in the rate of adrenaline secretion by the suprarenals. Removal of 0.1 of the blood was not certain to cause the hypersecretion of adrenaline. In the lumbar route expts. on the non-fastened non-anesthetized dogs the hemorrhage of $^1/_{15}$ of the total quantity of the blood was most effective in evoking an increase, though slight, of the adrenaline discharge. In general, the greater the hemorrhage, the greater and the longer the hypersecretion of adrenaline from the suprarenal capsule. The material difference between the 2 sets of expts. is attributed to the narcosis. L. W. Riggs

Tissue respiration and increase of erythrocytes in icterus. Ei-hichiro Tsukamoto. *Tohoku J. Exptl. Med.* **11**, 146–50(1928).—Obstructive icterus by ligation of the *Ductus choledochus* caused a diminution of O consumption of the blood and an increase in the production of erythrocytes. The cellular respiration of the kidneys and muscles is diminished and that of the liver is increased by obstructive icterus. L. W. Riggs

The abolition of stasis in inflamed blood vessels by alkali. J. H. Regenbogen. *Frankfurter Z. Path.* **36**, 280–315(1928).—The stasis of inflamed vessels can be removed by means of 3 $NaHCO_3$ soln. injections, given during $1^1/_2$ hrs., but the abolition is effected even better within 10 min. by means of a single injection of blood serum dialyzate, obtained from frogs which had been immersed in distd. H_2O. The effect is brought about by the diffusing OH ion. F. B. Seibert

The bromosulfalein test of liver function. Ernest Bulmer. *Lancet* **1928**, II, 325–6; cf. *C. A.* **21**, 1843.—It is safe for intravenous injection in a concd. soln., is non-irritant and in ordinary doses, absolutely non-toxic. Normal patients showed a retention in the blood of 5%, less or even none at all. In cases of liver disease there was a retention corresponding to the amt. of liver damage. The test is not one of biliary permeability, since many cases of complete obstructive jaundice did not give a 100% retention. F. B. Seibert

Relation of diabetes insipidus to the posterior lobe of hypophysis and to the tuber cinereum. Ginichi Sato. Pharmacol. Inst., Freiburg i. Br. *Arch. exptl. Path. Pharm.* **131**, 45–69(1928).—After removal of the hypophysis the tuber cinereum contains an active substance, resembling that of the posterior lobe, exerting an effect upon the uterus and on the production of urine. This substance is present in the tuber cinereum of the normal dog but in only a fraction of the amt. to appear after removal of the hypophysis. Its hormone action is evidenced by its effect in preventing diabetes following removal of the hypophysis and because if both hypophysis and tuber are destroyed diabetes develops. G. H. S.

Phosphate excretion by surviving section of tumor. Hermann Lange and Norbert Henning. Univ. Leipzig. *Arch. exptl. Path. Pharm.* **131**, 70–4(1928).—Shortly after removal from the body surviving tumor cells give up to the surrounding fluid considerable amts. of phosphoric acid; later less is given off. G. H. S.

Effect of potassium cyanide on the phosphate excretion of surviving tumors. HERMANN LANGE AND NORBERT HENNING. *Arch. exptl. Path. Pharm.* **131**, 75–9(1928).—Intoxication of surviving tumor tissue with KCN markedly increases the excretion of phosphate, an effect assocd. with death of the tumor cells. Exposure to low concns. of KCN cause a like, but less marked, effect, the reaction being reversible.
G. H. S.

Effect of narcotics on phosphate excretion by surviving tumor. HERMANN LANGE AND NORBERT HENNING. Univ. Leipzig. *Arch. exptl. Path. Pharm.* **131**, 115–8(1928).—Exposure of surviving tumor for a brief period to narcotizing concns. of phenylurethan cause a slight and reversible increase in phosphoric acid excretion, while longer exposure has a greater effect.
G. H. S.

Further studies on surviving tumor. HERMANN LANGE AND NORBERT HENNING. Univ. Leipzig. *Arch. exptl. Path. Pharm.* **131**, 119–26(1928).—Even after a few days tumor tissue retains its capacity to give up phosphate when exposed to narcotics.
G. H. S.

Nitrogen metabolism of normal and sarcomatous fibroblasts in pure cultures. LILLIAN E. BAKER AND ALEXIS CARREL. Rockefeller Inst. for Medical Research. *J. Exptl. Med.* **48**, 533–47(1928).—Both normal and sarcomatous fibroblasts of the rat utilize many different fragments of the protein mol. for their growth *in vitro*. α- and β-Proteoses have approx. equal growth-promoting power. A mixt. of peptones, peptides and NH_2 acids, contg. a negligible quantity of proteose, produces a temporary proliferation of normal fibroblasts, and an unlimited multiplication of sarcomatous fibroblasts, provided these substances are derived from liver which contains products of unknown nature that complete the nutritive effect of the protein degradation products. NH_2 acids contribute to the nutrition of the cells but are unable without the addn. of peptides or polypeptides to support their life. The proteolytic products are more toxic to normal than to sarcomatous fibroblasts. The hypothesis is suggested that the greater acidity produced by the large glucolysis of the sarcomatous cells may account for this difference through altering the speed of action of protein synthesizing enzymes.
C. J. WEST

Metabolism in epilepsy. IV. The bicarbonate content of the blood. WILLIAM G. LENNOX, assisted by MARGARET B ALLEN. *Arch. Neurol. and Psychiat.* **20**, 155–61(1928); cf. *C. A.* **22**, 111.—Blood was centrifugalized and the bicarbonate content of the plasma determined by the Van Slyke method in 100 epileptics. The normal plasma bicarbonate ranges between 55 and 70% by vol. In this series, 3 showed values below 55% and 9, values above 70%, but 49 were above 65%. Thus a tendency toward high normal values is shown, indicating that while the majority of patients show a normal acid-base equil in the body fluids, there is a slight tendency toward increased alky.
R. C. WILLSON

The results of the introduction of urine into the blood vessels. ENDERLEN, ZUKSCHWERDT AND FEUCHT. *Munch. med. Wochschr.* **75**, 30–1(1928).—A round piece contg. the ureter was cut from the bladder of a dog and implanted end-to-end into the vena iliaca. The toxic condition produced differs in several points from true uremia. It is assumed that the liver function is so disturbed during protein metabolism by the toxins which arise in the liver, that toxic products of decompn. are formed. No detoxifying action of the liver against the nephrogenic toxins was observed while an anastomosis between the ureter and the portal vein existed. These exptl. animals lived for a shorter time, but did not show the icterus which always appears after the introduction of urine into the cava. It was proved that the intoxication after the entrance of the icterus and the increase in the residual N can be reversible.
R. C. WILLSON

PONDER, ERIC: **The Erythrocyte and the Action of Simple Hemolysins.** London: Oliver and Boyd. 192 pp. Reviewed in *J. Lab. Clin. Med.* **13**, 1169(1928).

H—PHARMACOLOGY

A. N. RICHARDS

Asthma, adrenaline and blood pressure. W. KREMER. *Nederland. Tijdschr. Geneeskunde* **72**, I, 1795–1808(1928).—*Adrenaline injections (0.2 mg.) lower the blood pressure of asthmatics.* During an asthmatic attack the blood pressure is temporarily increased owing to an abnormally great filling of the lung capillaries, leading also to engorgement of the air passages, increased mucous secretion and Leyden Charcot's crystals. Adrenaline relieves the asthmatic attack by contracting the lung

capillaries back to normal size, thus lowering blood pressure. Spasmodic contraction of bronchial muscles is *not* held to be the cause of asthma, according to K. R. B.

Deposition of gold following intravenous treatment with sanocrysine. R. Korteweg, N. Waterman and C. Winkler Prins, Jr. *Nederland. Tijdschr. Geneeskunde* **72**, I, 2063–5(1928).—Rabbits, treated with sanocrysine doses larger than the clinical doses, exhibit a deposition of Au_2S_3 and metallic Au in the kidneys, the cornea and other organs. R. Beutner

The influence of heat and of quinine on the hemolysis of red blood cells in healthy and in sick individuals and after the use of various drugs. N. P. van Spanje. Onze Lieve Vrouwe Gasthuis, Amsterdam. *Nederland. Tijdschr. Geneeskunde* **72**, I, 2984–3001(1928).—A physiol. NaCl soln., with 0.15% quinine-HCl added, partially hemolyzes normal human blood if heated to 56.5°. At ordinary temp., a much higher quinine concn. is required for hemolysis; without quinine no hemolysis occurs at 56.5°. Blood of patients suffering from diabetes, pneumonia, blood or kidney diseases hemolyzes more readily in a quinine-contg. soln.; the same is true after taking drugs like arsphenamine insulin, quinine, salicylic derivatives, etc. R. Beutner

Remarks concerning the pharmacology of cinchophen D. Klinkert. *Nederland. Tijdschr. Geneeskunde*, **72**, I, 3663–9(1928).—A review. R. Beutner

The treatment of maniacal and depressive conditions by means of somniphen. W. Beyerman. *Nederland. Tijdschr. Geneeskunde* **72**, I, 3998–4003(1928).—Favorable reports are made on 10 cases. R. Beutner

Treatment of atrophic cirrhosis of the liver by means of calcium chloride. Jac. J. de Jong and A. Polak Daniels. *Nederland. Tijdschr. Geneeskunde* **72**, I, 4111–6 (1928). R. Beutner

Solutions of quinine in ethylurethan. Mario Giordani. Lab. Chim. della Sanità Pubblica, Roma. *Ann. chim. applicata* **18**, 239–44(1928).—Ethylurethan increases the soly. of quinine-HCl in water and renders the injection less painful (cf. Gaglio, Un nuovo preparato per l'iniezione ipodermica ed endovenosa della chinina, *Riforma medica*, May **1898**), but it makes the quinine salt unstable and toxic, particularly on exposure to light. Since, moreover, expts. by various investigators have shown that quinotoxine is readily formed from quinine-HCl, an investigation was undertaken by G. to det. whether there are substances which accelerate this *formation of quinotoxine*. Since ethylurethan renders quinine salts toxic, this was chosen as one of the substances to be tested. The method of Miller and Rhode (*Ber.* **27**, 1187, 1279 (1894); **28**, 1056(1895)) for forming quinotoxine and the expts. of Ganassini (cf. *C. A.* **16**, 2008) suggested testing various acids. The following data give the % quinine-HCl transformed to quinotoxine by the various reagents at the b. p. of the aq. or other soln. used: HCl none, H_2SO_4 8, AcOH 100, tartaric acid 100, citric acid 100, malic acid 100, lactic acid 100, HCl + AcOH 100, EtOH trace, $CHCl_3$ none, ethylurethan soln. 20. Quinotoxine is also formed when certain quinine salts are exposed to ultra-violet radiation. The accelerating action of the org. acids makes it probable that even when administered orally, quinine salts are transformed into quinotoxine provided that foods contg. org. acids have been taken. This may explain the *abnormal effects of quinine derivs.* so frequently encountered. In conjunction with expts. by Howard (*J. Chem. Soc.* **25**, 102(1872)) the results also show that prepns. for injection made with glycerol, ethylurethan, etc., become toxic because of the formation of quinotoxine. C. C. D.

Clinic on lead poisoning. I. S. Matussevich. Leningrade Inst. for the Study of Occupational Diseases. *Wiener klin. Wochschr.* **41**, 849–52(1928).—A positive correlation was found between lead poisoning and alcoholism, and between lead poisoning and low gastric acidity. Cases were more numerous in fall and winter months. D. B. Dill

The action of lecithin on the animal organism. M. T. Friedmann. State Med. Inst., Kharkov. *Z. ges. exptl. Med.* **53**, 17–43(1926).—Lecithin increases the development and activity of tadpoles and changes them to a lighter color. It increases the resistance of frogs to CO_2 in doses from 0.22 to 1.0 g. per kg. It increases the resistance to chloroform anesthesia, O lack and to warming. Similar results were obtained for warm-blooded animals in doses of 0.19 to 1.1 g. per kg. Lecithin increased the resistance of warm-blooded animals to CO and Br. F. E. Dunn

Effect of lecithin on the surviving heart of the frog. S. V. Ziganov. State Med. Inst., Odessa. *Z. ges. exptl. Med.* **53**, 72–81(1926).—Lecithin apparently acted upon the heart muscle direct and not through the sympathetic nor the parasympathetic systems. The efficiency of the heart was increased as shown by the systolic contraction and the tonus. The optimum concn. in the perfusion fluid of lecithin was 1:10,000. The beneficial action of lecithin on the heart explains its value in poisoning due to

chloroform, muscarine and other substances. Z. suggests that the beneficial action of certain endocrine products may be due to their lecithin content. Bibliography.
F. L. Dunn

Effect of thyroxine on the human organism. II. Hanns Löhr. Univ. Kiel. *Z. ges. exptl. Med.* **53**, 599–632(1927).—Clinical. Bibliography of 97 references.
F. L. Dunn

Chemical and pharmacologic properties of rhizoma Curcuma magna (Curry). A. Guttenberg. Univ. Wurzburg. *Z. ges. exptl. Med.* **54**, 642–52(1927).—From the alc. ether exts. a dye, curcuma yellow, a glucoside, an ethereal oil and a resin were isolated. The dye was pharmacologically indifferent. The osazone, m. 179–80°, and was inactive when injected into rabbits. The resin was fatal to rabbits in doses of 2.5 g. The ethereal oil was a terpene curcumen with the formula $C_{15}H_{24}$, levorotatory, and b_{12} 140–2°. 0.1–0.2% solns. in nutrient broth were bactericidal to *Staphylococcus aureus*. Cholesterol was 10% sol. in curcumen. It is excreted in the bile and appears in the urine in a glucuronic acid combination. It has a definite cholagog action and G. suggests that its bactericidal properties, its soly. for cholesterol and cholagog action suggest its value in hepatic and biliary disease.
F. L. Dunn

Chemical changes in the blood during asphyxia. I. Variations in calcium, potassium, residual nitrogen, fibrinogen, albumin and globulin content and blood cells. Rudolph Rittman. Univ. Innsbruck. *Z. ges. exptl Med.* **56**, 262–70(1927).—Mixts. of air low in oxygen were given to rabbits. The blood Ca rose. The residual N, fibrinogen, globulin and albumin showed no marked changes. The blood K was lowered.
F. L. Dunn

A case of poisoning by mercury vapor 150 years ago. R. Winderlich. *Chem.-Ztg.* **52**, 629(1928).—Supporting the contention of Stock (cf. following abstract) that many scientists have suffered from Hg poisoning, whether they realized it or not, an article of Achard (1778) is quoted in which irrefutable evidence is given that he himself contracted Hg poisoning by keeping a dish of Hg on the stove, although the room temp. was usually between 14° and 18° R. at the time.
W. C. Ebaugh

Danger of mercury and amalgam dental fillings. A. Stock. *Z. angew. Chem.* **41**, 663–72(1928).—The use of Hg in dental fillings (Cu or Ag amalgam) is especially deprecated as dangerous both to dentists and patients, as air containing 0.001 mg. of Hg per cu. m. is injurious to health.
B. C. A.

The toxicity of ethyl hypochlorite. V. Koelsch. *Zentr. Gewerbehyg. unfallverhütung.* **14**, 312–6(1927); *Bull. Hyg.* **1**, 234(1928).—It was not previously considered toxic. With animals a concn. of 0.004 g. per l. killed in 1–2 hrs.
George R. Greenbank

The action of arsphenamine preparations including stovarsol and tryparsol in experimental anthrax. N. Stolygvo. Lettlandischen Univ., Riga. *Centr. Bakt. Parasitenk. I Abt.* **102**, 364–7(1927).—Neoarsphenamine in large doses had considerable value, but stovarsol and treparsol have very little.
John T. Myers

Insulin, folliculin and glucemia in the normal dog. F. Rathery, R. Kourilsky and (Mlle.) Yv. Laurent. *Compt. rend.* **187**, 255–7(1928).—Folliculin restrains the action of insulin in the fasting animal. In the dog with alimentary hyperglucemia, folliculin prevents the usual reduction of the glucemia by insulin.
L. W. Riggs

Stovarsol, a specific in contagious agalactia in the sheep and in the goat. J. Bridré, A. Donatien and D. Hilbert. *Compt. rend.* **187**, 262–3(1928).—The precise nature of the organism which causes contagious agalactia is unknown. Subcutaneous injections of the Na compd. of stovarsol in doses not exceeding 0.03 g. per kg. acted as a true specific on the lesions of this malady which has hitherto resisted all medicinal treatment.
L. W. Riggs

Spirocheticide properties of the element vanadium. Asterogenesis around the particles of vanadium. C. Levaditi, P. Lépine and (Mlle.) R. Schoen. *Compt. rend.* **187**, 434–6(1928).—V should be included among the therapeutic substances active in spirochetosis. The element is efficient in inorg. and org. derivs., and especially in the elementary form and separate from other metals. V in powder with a fineness of 10 to 30 or 40μ is placed in suspension in 9 times its wt. of olive oil, and is administered by intramuscular injection in doses contg. 0.1 g. of V per kg. Sections of muscular tissue in treated animals show an asterogenic accumulation of microörganisms around the particles of V.
L. W. Riggs

Efficiency and safety of the prevention of goiter. O. P. Kimball. *J. Am. Med. Assocn.* **91**, 454–9(1928).—An extensive expt. in the prevention of goiter in Michigan by the addn. of 1 part KI to 5000 parts of common salt proved that this treatment was efficient and safe.
L. W. Riggs

Effects of ethylene-oxygen anesthesia on the normal human being. John D.

BRUMBAUGH. *J. Am. Med. Assocn.* **91**, 462-5(1928); cf. *C. A.* **22**, 3697.—The following conclusions were drawn from a study of 15 normal subjects under ethylene-O anesthesia for 1 hr., without preanesthetic medication and without operative or other complicating factors: There was no change in the hemoglobin, icterus index, coagulation time of the blood, character of the blood clot, urine or pulse rate. There was an increase in the blood sugar and in the systolic blood pressure. There was no change in the blood urea immediately following the anesthesia, but there was a definite increase averaging 18.7% in the blood urea 24 hrs. after anesthesia. There was a moderate but temporary decrease in the CO_2 combining power of the blood. L. W. RIGGS

Sulfur waters of Helouan-des-Bains, their composition and therapeutic value. S. NARKIRIER. *J. Egyptian Med. Assocn.* **11**, 57-72, 114-28(1928). (In French.)—The Helouan (Egypt) springs are classed as mineral waters, and are among the richest in the world in H_2S. Eight outcrops of the water are known. Five of these sources, which are located near the Thermal Establishment, have a combined output of 785,000 l. per day of water of identical compn. at 32° and contg. 54 to 59 mg. of H_2S per l., 4.8 g. of NaCl and 0.57 of bicarbonates calcd. as $NaHCO_3$. It is stated that H_2S is readily absorbed into the circulation when taken by drinking the water, bathing in the water, or by inhalation of the H_2S gas. It is claimed that the absorbed H_2S has an antiseptic action, that it facilitates respiratory exchanges between the blood and the tissues by activating the combustions, that it increases the general metabolism, and that it corrects the metabolism of S by bringing this element to the cells in an easily assimilable form. The treatment of various diseases by baths in the Helouan springs is described at length. L. W. RIGGS

Accidents and complications occurring during the treatment of bilharziasis by antimony compounds. M. KHALIL. *J. Egyptian Med. Assocn.* **11**, 97-106(1928); cf. *C. A.* **21**, 135.—The precise routine for the prepn. and administration of tartar emetic in bilharziasis is described. When this technic is followed rigidly, accidents and complications are of rare occurrence. L. W. RIGGS

Milk in therapeutics. TH. DOMEC. *Rev. gen. sci* **39**, 427-30(1928); cf. Barkan and Nelson, *C. A.* **18**, 1138; Högler, *C. A.* **18**, 2386.—A review of the action of milk when administered by subcutaneous or intramuscular injection L. W. RIGGS

Influence of narcosis on the immune bodies. KEN IINO. *Sei i-Kwai Med. J.* **47**, 14 44(1928).—During ether anesthesia in rabbits there was a slight decrease of agglutinins 30 to 60 min. after narcosis, with recovery in 2 hrs. Hemolysin, bacteriolysin and Forssman's antibody and complement were not affected except that they disappeared more readily than in control rabbits. With $CHCl_3$ anesthesia, agglutinins showed a decrease in 30 to 120 min. after narcosis, followed by recovery in 3 hrs. Hemolysin, bacteriolysin and Forssman's antibody and complement were affected the same as in ether narcosis. Injection of pantopon-scopolamine in rabbits did not affect the immune bodies or complement. L. W. RIGGS

Pharmacologic study of the absolute pressure of the heart. I. Study of the frog heart. ITARO KIKUCHI. *Tôhoku J. Exptl. Med.* **11**, 116-41(1928).—Ca, adrenaline, digitalis and veratrine increase the abs. pressure of the frog heart. Caffeine, quinine, physostigmine, atropine and histamine in small doses increase the abs. pressure and in large doses decrease it. K, Ba, pilocarpine, sparteine, apomorphine, alc., camphor and morphine in both small and large doses cause a reduction in the abs. pressure of the frog heart. Mg generally causes a reduction of the pressure. No definite connection appears to exist between the changes of abs. pressure of the heart under the influence of the above-named drugs and the heart rate and min. vol. L. W. RIGGS

Toxic stimulation of the vasomotor center. I. KARL JUNKMANN AND WILHELM STROSS. Univ. Prag. *Arch. exptl. Path. Pharmakol.* **131**, 1-17(1928).—**II.** WILHELM STROSS. *Ibid* 18-44.—Of all substances tested CO_2 exerts the strongest pressor effect. Caffeine, strychnine and camphor have but little influence upon the blood pressure as compared with cardiazole, coramine, hexetone, the ammonium salts and pyramidone. When the vasomotor center is under marked paralysis, caffeine and strychnine at times cause a slight increase in blood pressure when injected into an artery for transport directly to the brain. Caffeine, strychnine and picrotoxin do not noticeably increase the irritability of the vasomotor center for CO_2 or its reflex irritability. Curare appears to act in contributing to increased blood pressure in much the same way. G. H. S.

Effect of urea on the skeletal muscle of frogs. E. GABBE AND R. HOFER. Univ. Würzburg. *Arch. exptl. Path. Pharmakol.* **131**, 92-114(1928).—In frogs which have received 2.5-10 g. of urea per kg. the mech. irritability is considerably increased. The muscle intoxicated with urea responds to slight mech. stimulation with a prolonged

contraction. Sensitivity to direct elec. stimulation is not modified, but when applied through the nerve the irritability of the muscle is increased. After urea administration a max. elec. stimulation causes a contraction curve of increased height and duration. Urea diminishes the extensibility of the muscle and increases its max. performance of work. Isolated muscles suspended in physiol. NaCl are stimulated by the addn. of 0.5–1% urea. Curarization abolishes the action of urea, which acts through the nerves and their endings. G. H. S.

Influence of thyroid substance on the effect of splanchnic stimulation upon the blood pressure. E. FLATOW AND M. MORIMOTO. Univ. Berlin. *Arch. exptl. Path. Pharmakol.* **131,** 127–37(1928); cf. *C. A.* **22,** 1408.—Thyroid substance as well as non-sp. protein modifies the effect of splanchnic stimulation upon blood pressure, an effect apparently referable to the influence of the adrenaline secreted. G. H. S.

The "all-or-none law" of narcosis and the criticism of Hans Winterstein. G. MANSFELD. Univ. Pécs. *Arch. exptl. Path. Pharmakol.* **131,** 268–78(1928). G. H. S.

Validity of the "all-or-none law of narcosis" with the vegetative nervous system. KATHERINA HECHT. Univ. Pécs. *Arch. exptl. Path. Pharmakol.* **131,** 289–96(1928).—The all-or-none law of narcosis is valid for the behavior of the heart vagus. G. H. S.

Effect of adrenaline and of some other internal secretions on the contraction of mammalian skeletal muscle. HELENE WASTL. Univ. Wien. *Arch. ges. Physiol.* (Pflüger's) **219,** 337–90(1928).—Following the intravenous injection, in cats, of adrenaline muscular contraction consequent to elec. stimulation of nerves was detd., showing that one of 4 effects may be exhibited: (*a*) a simple reduction in the height of contraction (occurring in 25% of the ♂, in 37.2% of the ♀ animals tested), (*b*) an increase in the height of contraction (♂ 37 [illegible] ♀ 19.3%), (*c*) an initial transitory increase followed by a fall (♂ 25.8%, ♀ 19.3%), and (*d*) no change (♂ 11.6%, ♀ 24.2%). In all 836 animals were tested. The distribution of results with reference to sex is influenced by adrenaline dosage. The effect of adrenaline upon blood pressure is also influenced by sex, for although within physiol. limits adrenaline induces the same effect in both ♂ and ♀ cats, to higher concns. the ♀ animals are found to be the more sensitive. In all respects exts. of fresh adrenals act as do adrenaline prepns. Thyroid substances had no direct effect upon the muscle, although after thyroid treatment, as after injections of hypophysis, adrenaline is less effective. In high concns. hypophysin inhibits muscular contraction, apparently because of vasoconstriction and asphyxia of the muscle. Aside from its effect on the peripheral circulation histamine apparently exerts a direct toxic action in the muscle. Although reacting upon the vasoconstrictors, ergotamine causes no direct damage to the muscle. G. H. S.

Influence of cholesterol on experimental tuberculosis. RICHARD E. SHOPE. Rockefeller Inst. Med. Research. *J. Exptl. Med.* **48,** 321–37(1928).—Cholesterol, administered intraperitoneally, in these expts. definitely prolonged the lives of tuberculous guinea pigs when the infection was of an acute type produced by inoculation with a small dose of very virulent human type organism, but did not definitely prolong the lives when the infection was of the chronic type produced by the injection of a small dose of human type tubercle bacilli of relatively low virulence, or when the infection was more acute owing to the injection of a large dose of organisms of low virulence. It had no beneficial effect on an acute type of infection produced by the bovine type organism. Cholesteryl chloride, toluide, anilide, Na cholesterol sulfate and quinine cholesterylate did not significantly prolong the lives of tuberculous guinea pigs. Na cholesterylate, in optimal dosage, definitely prolonged life. There was a significant shortening in the duration of life of tuberculous guinea pigs subjected to the trauma of intraperitoneal injection and repeated handling as compared with tuberculous guinea pigs that were not handled or traumatized by intraperitoneal injections. C. J. W.

The cerebral circulation. IV. The action of hypertonic solutions. H. G. WOLFF AND H. S. FORBES. *Arch. Neurol. and Psychiat.* **20,** 73–83(1928).—After cats had been anesthetized with 1% solns. of isoamylethylbarbituric acid, solns. of NaCl, dextrose and urea were injected. Such hypertonic solns., intravenously or intraperitoneally, effect a constriction of the pial blood vessels, demonstrable microscopically and photographically. Increased osmotic tension of the blood seems to be the chief factor in causing this vasoconstriction. The pial artery diam. changes independently of the blood and intracranial pressures. R. C. WILLSON

Symposium on alcohol. Alcohol in its biological aspects. CHAS. R. STOCKARD. *Med. J. and Record* **127,** 195–7(1928). **The medicinal use of alcohol in the acute infectious diseases.** SAMUEL W. LAMBERT. *Ibid* 197–99. **The use of alcohol in the circulatory defects of old age.** HARLOW BROOKS. *Ibid* 199–206. **The alcohols: their**

practical utility. WM. H. PORTER. *Ibid* 206–9. **Alcohol and prohibition.** GREGORY STRAGNELL. *Ibid* 210.—Symposium with some discussion. R. C. WILLSON

The effect of kalzan on the blood calcium. BERNARD S. KAHN. *Med. J. and Record* **127,** 600(1928).—Nine g. of kalzan, a commercial Ca prepn., was dissolved in 250 cc. H_2O and given to the test subjects after a 12-hr. fast. The circulating blood Ca was raised in each instance. A typical protocol follows: Ca value before kalzan ingestion, 10.40 mg. per 100 cc. blood. Ca value 4 hrs. after kalzan ingestion, 12.60; 5 hrs., 14.32; 6 hrs., 1754; 12 hrs., 10.80. The peak of increase comes at the 6th hr., but hypernormal values exist for about 12 hrs. These results are very comparable with those following the use of Ca lactate. R. C. WILLSON

The activity of iron and its practical importance. K. KÖTSCHAU AND A. SIMON. *Münch. med. Wochschr.* **75,** 122–4(1928); cf. *C. A.* **22,** 3731.—The authors' investigations show that ferro-hydrocarbonate reacts catalytically with benzidine, guaiac, etc., in the presence of H_2O_2. This catalytic activity is always present as long as ionized bivalent Fe can be detected by means of the specific Kröhnke's isonitroacetophenone reagent. Mineral water shows the same activity under the same conditions. The aging process depends upon the oxidation of Fe^{++} to Fe^{+++} with the formation of brown $Fe(OH)_3$. Aging is impossible without the oxidizing agent. In the presence of O_2 the aging process is sharply accelerated by the action of light. In the Stuttgart-Canstatt iron mineral baths, opportunity is given for the internal and external use of catalytically active ferrous Fe. R. C. WILLSON

Recent work in the field of chemotherapy. GIEMSMA. *Z. angew. Chem.* **41,** 731–7 (1928). E. H.

Progress in chemotherapy in the field of veterinary medicine. A. WOLLERSHEIM. *Z. angew. Chem.* **41,** 145–7(1928). E. H.

R. A. GORTNER

The action of extremely dilute solutions of metallic salts on the growth and development of tadpoles. KARL KÖNIG. Univ. Wien. *Z. ges. exptl. Med.* **56,** 581–93 (1927).—A rhythmic variation in growth and development was observed for Pb and Ag nitrate with increasing diln. F. L. DUNN

Hydrogen-ion concentration of fish muscle. C. C. BENSON. Univ. Toronto. *J. Biol. Chem.* **78,** 583–90(1928).—The p_H of fish muscle was detd. by covering a freshly cut surface with powd. quinhydrone, inserting a bare Pt electrode, and reading the voltage of this combination against a calomel electrode. Fatigued muscle of the haddock was acidic at the time of death and varied only slightly during the changes of rigidity. Rested muscle showed an alk. reaction which gradually changed to the acidic values of fatigued muscle. The muscle of the hake fish was alk. 5 hrs. postmortem and never gave an acid reaction. Cod muscle remained neutral and varied only slightly. ARTHUR GROLLMAN

The question of the specificity of the intracellular dehydrogenases. I. The dehydrogenase of cunner muscle. MARY E. COLLETT. Western Reserve Univ. and Marine Biol. Lab., Woods Hole. *J. Biol. Chem.* **78,** 685–9(1928).—In the muscle of the cunner fish, a single dehydrogenase is present. It is capable of oxidizing anaerobically several donators, *viz.*, succinic, citric, glycerophosphoric, lactic, *l*-malic, acetic and butyric acids. ARTHUR GROLLMAN

Study of the blood meal of the anophelines in the Dutch East Indies, with the aid of the precipitin reaction. I. E. W. WALCH AND M. SARDJITO. *Geneeskund. Tijdschr. Nederland. Indië* **68,** 247–68(1928).—The study of the blood contained in the stomach of several species of anophelines showed that the preference for human blood runs parallel to the frequency with which a mosquito acts as a malaria carrier. M. J.

Effect of salt desequilibration on some marine organisms. E. KREPS. *Russkij fisiol. zhurnal* **9,** 118–9(1926); *Ber. ges. Physiol. exptl. Pharmakol.* **44,** 633–4.—*Balanus* (*Crustacea, Cirrhipedia*) is resistant to considerable variations of osmotic pressure. While in the normal medium systole and diastole are equally strong, the former is increased and the latter is weakened by the addn. of Na or K. Mg and Ca have the reverse effect. Loeb's law of salt antagonism is thereby confirmed. The relation Na + K/Ca + Mg which characterizes each stage of activity remains largely const. even if the salt content of the water varies considerably. MARY JACOBSEN

The influence of temperature on the photosensory latent period. S. HECHT. Columbia Univ. and Zoöl. Station, Naples, Italy. *J. Gen. Physiol.* **11,** 649–56(1928).

The relation of time, intensity and wave length in the photosensory system of Pholas. *Ibid* 657–72.—Largely physiol. but of interest to students of photochemistry. C. H. R.

The influence of oxygen tension upon the respiration of unicellular organisms. WM. R. AMBERSON. *Biol. Bull. Marine Biol. Lab.* **55**, 79–91(1928).—The respiratory exchanges of *Paramecium* and of fertilized *Arbacia* eggs were practically const. over a wide range of O tensions. In the fertilized *Arbacia* egg the O consumption was practically const. between 228 and 20 mm. Hg partial pressure of O. Between 80 and 20 mm. Hg there was a slight diminution of O intake. At 20 mm. Hg the consumption of O was about 90% of that at atm. pressure. Below 20 mm. Hg the O consumption was sharply reduced. The cleavage of *Arbacia* eggs proceeds at a normal rate down to very low tensions of O. Below 11 mm. Hg the rate became slower and cleavage ceased at 4 mm. Hg. L. W. RIGGS

Comparison of the oxygen consumption of unfertilized and fertilized eggs of Fundulus heteroclitus. MARJORIE BOYD. *Biol. Bull. Marine Biol. Lab.* **55**, 92–9(1928).—By 3 methods it was shown that the O consumption of the eggs of *Fundulus heteroclitus* was greatly increased after fertilization. This increased rate of O consumption was at its max. from 60 to 90 min. after the addn. of the sperm in a period immediately preceding the first cleavage. The O consumption then fell to a level practically identical with that of unfertilized eggs. L. W. RIGGS

The bacteriological sterilization of Paramecium. ARTHUR K. PARPART. Amherst Coll. *Biol. Bull. Marine Biol. Lab.* **55**, 113–20(1928). L. W. RIGGS

Oxygen consumption of insect eggs. ROY MELVIN. Iowa State Coll. *Biol. Bull. Marine Biol. Lab.* **55**, 135–42(1928).—Factors accompanying and influencing metabolism as detd. by O consumption during embryonic development of *Anasa tristis* DeG., *Tropoea luna* L., *Samia cecropia* L and *Pyrausta ainsliei* Heim show that the wt. of the shell is an important factor and that the effects of temp. are not as pronounced during the formative period as during the period of late incubation. The variation in the length of the formative period appears to depend on the length of the incubation period and not on the place where the eggs chance to be laid as has been suggested. L. W. RIGGS

Chemical constitution and metabolism of fat bodies in insects. JEAN TIMON-DAVID. *Bull. soc. chim. biol.* **10**, 784–95(1928); cf. *C. A.* **21**, 2741.—The subject is reviewed historically with 26 references to the literature. The tissues were ground and dried with precautions to avoid oxidation, and the fats were extd. with Et_2O or $CHCl_3$. The usual analytical figures were detd. for 7 fats and the results are classified as follows: (1) semi-drying oils from *Thaumetopaea Pityocampa* S., *Sericaria Mori* L., (2) non-drying oils from *Tenebrio molitor* L., *Pyrausta nubilalis* Hubn, *Cossus ligniperda* F., *Ergates faber* L., (3) semi-drying fats from chrysalides of *Pieris brassicae* L., (4) non-drying fats from *Oryctes nasicornis* L., *Myelobia smerintha* Hubn, (5) fats with very high indices of sapon. and very low indices of I (butters) from *Pemphigus utricularius* Pass., and *P. cornicularius* Pass. The second of the above classes includes the majority of insects studied. The diversity of fats in insects is remarkable. L. W. RIGGS

Toxic action of acids of the formic series in relation to the adaptation of the organism. J. BĚLEHRÁDEK AND F. SCHWARZ. *Bull. soc. chim. biol.* **10**, 909–19(1928).—The time of survival (T) of tadpoles of *Rana fusca*, *Tubifex* (*rivulorum*), *Daphnia* and the vinegar eel *Anguillula aceti*, placed in aq. solns. of formic, acetic, propionic, butyric and valeric acids, resp., of different concns. (C) is expressed by the formula $T = A/C^b$, in which A and b are consts. Notwithstanding the similarity of this formula to the equation for adsorption, the toxic action of these acids is not detd. by adsorption alone, the exponent b in the majority of cases being greater than 1. There appears no relation between the toxicity of these acids and their surface tension. The order of toxicity of the acids is not the same at different concns. The vinegar eel presents the greatest resistance to the acids of this series, in particular to acetic and propionic acids. L. W. RIGGS

Specific dynamic action in beetles. A. GOURÉVITCH. *Compt. rend.* **187**, 65–7 (1928).—The ingestion of sugar in the beetle, *Periplaneta orientalis*, increased the consumption of O but slightly or not at all. Beetles fed casein or albumin increased their gaseous exchange an av. of 40%. This increase is attributed to sp. dyanmic action. L. W. RIGGS

Lipase of the larvae of Galleria mellonella. V. PERTZOFF. *Compt. rend.* **187**, 253–5(1928).—The fat was extd. from the ground larvae with acetone and the residue of the larvae was dried over H_2SO_4. The lipase was extd. from the dried powder by glycerol, $N/1$ NaCl or dil. NH_4OH. A soln. in $N/1$ NaCl, preserved with toluene, hydrolyzed emulsions of olive oil and beeswax. At 45° the lipase had a hydrolyzing

action on the bacilli of tuberculosis. In general the results previously reported by S. Metalnikov are confirmed. L. W. Riggs

Does radium act on insects during their metamorphosis? (Mme.) Hufnagel and deNabias. *Compt. rend.* **187**, 431–3(1928).—Both pupae of *Calliphora* and caterpillars of *Hyponomenta* subjected to strong irradiation by γ-rays showed no appreciable modifications of their constituent elements. L. W. Riggs

Rufine, a tegumentary pigment of Arion rufus. Ch. Dhéré and Chr. Baumeler. *Compt. rend. soc. biol.* **99**, 492–6(1928).—The process of extn. of rufine from *A. rufus* is described. The ext. presents many color changes under different conditions of acidity, concn. and oxidation. Further work is in progress. L. W. Riggs

Influence of sodium fluoride on frog sperm. Jean Rostand. *Compt. rend. soc. biol.* **99**, 502–3(1928).—Toad eggs fertilized with frog sperm which had been treated for several min. with a 1 to 150 soln. of NaF gave embryos some of which lived 10 days. L. W. Riggs

The effect of chemicals on viscosity of protoplasm of ameba as indicated by Brownian movement. Floyd J. Brinley. Univ. of Pennsylvania. *Protoplasma* **4**, 177–86 (1928).—The culture medium contg. *Amoebae proteus* was placed on a thin slide under a cover glass. A drop of the chemical to be tested was placed on the edge of the cover glass and allowed to diffuse under it. The organisms were observed microscopically with dark field illumination. HCN ($M/300$) produces an initial increase in viscosity which is immediately followed by a liquefaction of the protoplasm. HCl ($M/36$) causes a solidification of the entire organism and NaOH produces a liquefaction. CO_2 (satd. aq. soln.) produces a gelation of the ectoplasm and a soln. of the endoplasm. NaCl ($M/16$) and KCl ($M/7.5$) produce a liquefaction. $CaCl_2$ ($M/11$) and $MgCl_2$ ($M/20$) cause a solidification of the protoplasm. Alc. $CHCl_3$ (satd. aq. soln.), and ether (4%) produce a final soln. of the protoplasm. M. H. Soule

Function of the inter-renal organs of selachians. Bruno Kisch. Zoöl. Sta., Naples. *Arch. ges. Physiol.* (Pflüger's) **219**, 426–61(1928).—Removal of the organs leads to condensation of the pigment in the chromatophores of the skin, retardation of respiration and an inverse motor respiratory reaction, muscular weakness and inertia, contraction of the body muscles, hypersensitiveness to lack of O, and finally death. These facts, taken in conjunction with the known effects of adrenalectomy in mammals, suggest that these organs deliver to the blood stream a substance which favors the oxidative decompn. of certain metabolic products that are toxic. Injections of acid exts. of inter-renal tissue cause, in animals which have been operated upon, the symptoms to diminish or to disappear, while injections of sea-water, adrenaline or liver exts. are inert. G. H. S.

Behavior of phosphoric acid in artificially perfused frog muscle. Tohoru Kitano. Univ. Greifswald. *Arch. ges. Physiol.* (Pflüger's) **219**, 500–13(1928).—Phosphoric acid formation and recombination is to a high degree dependent upon the O supply. G. H. S.

The salmon canning industry (Clark, Clough) **12**.

12—FOODS

F. C. BLANCK AND H. A. LEPPER

Preservatives allowed in foodstuffs in Germany. G. Riess. *Reichsgesundheitsblatt* **2**, 359–61(1927); *Bull. Hyg.* **3**, 400.—An account of the regulations. Tables are given showing the max. amts. of H_3BO_3, borates, H_2SO_3, HCHO, $(CH_2)_6N_4$, HCOOH, C_6H_5COOH and benzoates permissible; also where certain of the above preservatives may not be used. George R. Greenbank

The retention of the antiscorbutic vitamin after sterilization. E. Remy. Inst. Hyg. Univ. Freiburg. *Z. Untersuch. Lebensm.* **55**, 385–93(1928); cf. *C. A.* **22**, 3388.—Cauliflower, green beans, green peas, carrots, spinach and tomatoes were sterilized by heat (canned) and tested after from 1 to 7 months for vitamin C by standard animal tests with guinea pigs. The animal tests were checked by comparison with Bezssonoff's reagent. Cauliflower, green beans and carrots failed to hinder the development of scurvy symptoms except in large doses while green peas, spinach and tomatoes retain a considerable amt. of the antiscorbutic factor. The Bezssonoff color reaction, in general, ran parallel to the animal tests. C. R. Fellers

Scientific control in the flour milling industry. C. W. Herd. Woodlands, Ltd., Dover. *Food Manuf.* **3**, 455–7(1928); cf. *C. A.* **22**, 2998.—The industrial chemist's work may be divided into (1) investigation of raw material, (2) control during the

mfg. process and (3) examn. of the finished product. The cereal chemist is no exception and the work of the mill lab. is considered under these headings. J. A. K.

The bleaching of flour. C. H. Schweizer. Lab. Bd. Health, Bern. *Mitt. Lebensm. Hyg.* **19**, 223–35(1928).—A general discussion of imported bleached flour with suggestions as to analytical procedures for its detection. C. R. Fellers

Nutritional bread (tomato). J. Boyd. *Food Manuf.* **3**, 446(1928). J. A. K.

Preservative tablets and preserved milk samples. L. M Lambert. Calif. Dept. Agr., *Mo. Bull.* **18**, 449–53(1928).—Milk preservative tablets from 11 sources were examd. chemically. $HgCl_2$ was present in all, varying from 41 to 80%. NH_4Cl was present in some tablets and increased the soly. of the $HgCl_2$. Citric acid was present in 1 sample which had been found previously to cause curdling. Boric acid was a common constituent. Milk samples preserved by the use of these tablets were not always sterile. CH_2O was less effective than $HgCl_2$. A finely divided flocculent substance was suspended in the preserved milk samples, although this fine curd apparently did not appreciably influence the fat or other tests. A very slight decrease in fat percentage was found in the preserved samples. This decrease was greatest where $HgCl_2$ was present in the preservative. C. R. Fellers

The grading of milk and cream for manufacturing purposes. Frank H. McCampbell. Calif. State Dept. Agr. *Mo. Bull.* **16**, 692–700(1927).—Grade definitions and practical suggestions to dairymen and creamery operators for maintaining high-grade dairy products. C. R. Fellers

Determination of added phenol and cresol in milk. H. T. Fawns. *Analyst* **53**, 489–90(1928).—The method of Mumford (*C. A.* **7**, 2734) for the detection of phenol in the presence of other org. substances is applied to the analysis of milk. Taste and smell cannot detect less than $^1/_{10,000}$ parts of phenol; the reaction used is quant. for 5–100 mg. of phenol per 50 cc. of milk. W. T. H.

A new method for determining fat in milk and cream bonbons (cream chocolates). Hans Barsch. *Chem. Ztg.* **52**, 659(1928).—Dissolve 25 g. of the candy in 100 cc. hot H_2O in a 500-cc. flask, add 10 cc. of 25% NH_3 soln., 50 cc. EtOH (96%) and 100 cc. of HCl-free C_2HCl_3, and boil with a reflux condenser for 20–30 min. Cool, remove carefully to a separatory funnel, allow to run over a filter contg. kieselguhr, and then into a 50-cc. buret for settling. Transfer the C_2HCl_3 to a glass dish, evap. and weigh. The fat is very clean and pure. W. C. Ebaugh

Some data concerning the composition of California creams. N. C. Smith. Div. of Chem., State Dept. Agr., Calif. State Dept. Agr., *Mo. Bull.* **16**, 728–36(1927).—Analysis of 20 samples of cream showed the % of CaO in the ash was the least variable factor and of the greatest significance in detecting the neutralization of cream with lime. Sapon., I, Polenske, Reichert-Meissel and modified Valenta nos. fell within the general range for normal butters and were of little value in detg. neutralization. The acidity as oleic acid likewise was of little value. Seventeen references are appended. C. R. Fellers

Water in cream. A. F. Lerrigo. *Analyst* **53**, 488–9(1928).—Analysis of 8 samples of cream shows that it is common practice for dairymen in England to dil. cream with 2–30% of water. W. T. H.

Some ice cream problems. A. E. Reynolds. Calif. State Dept. Agr., *Mo. Bull.* **17**, 402–6(1928).—The new Calif. standard for ice cream, *i. e.*, 1.6 lb. food solids per gal., is discussed. Only high-grade gelatin or vanilla ext. should be used in ice cream manuf. C. R. Fellers

Detection and determination of starch in margarine. A. Schmidt. Milchwirtschaft. Inst. für Hannover. *Chem. Ztg.* **52**, 671(1928).—Since July 1, 1915, 2–3% of potato starch can be used instead of 10% of sesame oil to make margarine readily distinguishable from butter. Starch is detected microscopically by treatment of margarine on the slide with tincture of iodine, giving the characteristic blue color. Or the margarine may be melted below 60°, the fat sepd. and the residue tested with tincture of iodine. Sesame oil is tested for by Baudouin's or Soltsien's reactions. To det. starch, melt 100 g. of margarine below 60° in a 200-cc. beaker, remove the melted fat by filtration and washing with Et_2O until the residue and filter are fat-free, and then transfer the filter and contents (albumin, H_2O and starch) to a wide-mouth 100-cc. flask, treat twice with 25-cc. portions of 1% HCl soln., shake thoroughly, and heat in a boiling water bath for 15 min. Add 30 cc. H_2O, cool, add 10 cc. of 4% phosphotungstic acid soln., fill to the mark, shake, filter and polarize. Multiply the Ventzke-polarimeter degrees by 0.346 and calc. thus: Let c = the amt. of starch, α = angle, $[\alpha]_D$ = factor (for potato starch 195.4), l = length of polarization tube in dm.; then $c = 100.\alpha/[\alpha]_D.l$. W. C. Ebaugh

Ripening of cheese of "Sbrinz" type. M. Solari. *Anal. ofic. quím. prov. Buenos Aires* **1**, 107–40(1927).—Analyses of "Sbrinz" cheese were made at intervals during ripening over a period of 11 months. Figures are given of the variation in content of moisture, fat, nitrogenous material (NH_3, amines, sol. and insol. albumins), ash, NaCl, and acidity. A notable feature was the fall of acidity to zero after 4 months, followed by a rapid rise apparently connected with degradation of the fat. NH_3, sol. albumin and amino compds. showed an increase parallel with the degree of ripeness. Lactose had already disappeared when the observations were started. The results are discussed. B. C. A.

Researches on the use of potassium nitrate and nitrite in the curing of meats. Gustav Riess, Rudolf Meyer and Walter Müller. *Z. Untersuch. Lebensm.* **55**, 325–54(1928).—Comprehensive chem. and bacteriol. investigations showed that KNO_3 changes to KNO_2 in meat pickle. The change requires about 3 weeks for completion. By addn. of $NaNO_2$ the curing process is greatly accelerated and the time is reduced from $^1/_2$ to $^1/_4$. The reddening of the meat due to the change of the hemoglobin to NO_2-hemoglobin promotes the penetration of salt into the flesh. The addn. of 0.6% $NaNO_2$ to the NaCl required for the pickle was sufficient for rapid curing. In the outer layers of cured meat 20 mg. $NaNO_2$ per 100 g. of meat was found while in the inner layers the quantity was only 1 to 2 mg. So far as appearance, odor, taste and keeping quality of the cured meats are concerned, $NaNO_3$ is at least the equal of $NaNO_2$. C. R. Fellers

Treatment of meats via the blood stream. A. Gauducheau. *Ann fals.* **21**, 84–90 (1928).—The flesh of chickens, rabbits, pigeons and even sheep can be flavored as required by injecting suitable sauces, etc., directly into the blood stream, through the heart or one of the main arteries, after the animal has been bled. The flesh readily takes up the aroma, and the changes taking place are being studied with a view to the com. application of the technic. A. Papineau-Couture

The differentiation of thawed frozen meat from fresh meat. Anon. *Mitt. Lebensm. Hyg.* **19**, 219–22(1928).—The p_H detn. offers no means of differentiation. The ext. from the thawed meat is usually more turbid than that obtained from fresh meat. The electrolyte content of the exts. cannot be used with certainty as a basis of differentiation. C. R. Fellers

The salmon canning industry. IV. Food value of canned salmon. V. Ernest D. Clark and Ray W. Clough. *Food Manuf.* **3**, 421–3, 460–3(1928); cf. *C. A.* **22**, 2794.—The authors have dealt with the life history of the salmon, methods employed in its capture, the plant, processes used at the Western Canneries, characteristics of the different species of fish, food value of the canned salmon, seasonal prepn. for salmon, regulation and control, economic importance of the industry and scientific investigations in that lab. J. A. Kennedy

A new means of detecting spoiled or worked over nutrient fats. J. Grossfeld. Govt. Food Lab., Berlin. *Z. Untersuch. Lebensm.* **55**, 376–85(1928).—In 2 cases where white grease was worked up with lard, the *caprylic acid value* was, resp., 7.5 and 8.0. Normal lard showed a value of less than 1, but when heated to 150° or over in the presence of air, the caprylic acid value increases considerably. By heating in an atm. of CO_2 or during hydrogenation, no appreciable change was observed. The rancidity of fats is closely associated with their caprylic acid value. The alk. aq. soap solns. of rancid fats decolorize the alk. form of thymolphthalein. By long exposure to ultraviolet light, lard undergoes rancidity as evidenced by the caprylic acid value and Kreiss tests. It is probable that an oxidation deriv. of oleic acid is thus formed. C. R. F.

Artificial coloring of soup pastes. Jose Agell y Agell. *Quim. Ind.* **5**, 161–3 (1928).—Coloring of soup pastes is permitted in Spain, provided the color is harmless and its presence is stated on the package. Only yellow and red are used. *Naphthol, Yellow S* and *Ponceau R.* are permitted in Spain, France and Italy, being originally placed on the list of harmless food colors by the Congrés International pour la Suppression des Fraudes. One % Naphthol Yellow alone or blended with 0.05% Ponceau RR is sufficient. In view of the great no. of harmful products brought on the market under fancy names A. suggests that the purchase and distribution of food colors be delegated to the Natl. Federation of Mfrs. of Soup Pastes, which is to buy on a guarantee of quality and concn. and to analyze the dyes for toxic metals. Mary Jacobsen

The effect of sugar, acid and "set" on the keeping properties of jams. F. Hirst. Campden Res. Sta., Glos. *Food Manuf.* **3**, 447–50(1928).—Expts. were carried out to ascertain (1) what sugar concn. is necessary to prevent fermentation and mold growth, (2) the inhibiting effect of acid on the growth of yeasts and molds and (3)

whether the "set" of the jam plays any part in preventing fermentation. Sep. samples were inoculated with (*a*) *wild yeast* isolated from a fermenting sample of cold process jam and (*b*) the common blue mold, *Penicillium glaucum*. Expts. show that the keeping property of jam depends on sugar, acid and the "set." In a well-set jam, it is difficult for the yeasts to get into the body of the jam, and jams prepd. contg. only 60% sugar, but with a good set, have kept for over 12 months and have shown no signs of fermentation. Sixty-five % sugar is necessary to prevent slight fermentation, if wild yeasts gain access. *Penicillium glaucum* did not grow when the sugar content was 65% or over. Some of these have developed *Penicillium glaucum* when stored in a damp atm. However, jams contg. over 65% sugar are too sweet and tend to crystallize when stored. Acid does appear to have a slight effect on the growth of yeast, but in the strength used (0.5–1%) it has no appreciable effect on the growth of *Penicillium*.
J. A. Kennedy

Commercial tomato preserves. C. Ferri. *Anal. ofic. quim. prov. Buenos Aires* **1,** 141–91(1927).—The chem. and microscopical examn. of tomatoes preserved in various forms is outlined, and a series of representative analyses is given. The essential detns. are of poisonous metals, preservatives, coloring matter and starch. Over 6% of starchy material indicates adulteration, and NaCl over 1% an addn. of salt. Microscopical examn. yields evidence of the efficiency of sterilization and of the presence of other pulps, such as papaw or carrot. B. C. A.

Chemical compositions of the juices of some American apples. Joseph S. Caldwell. U. S. Dept. Agr. *Fruit Products J. and Am. Vinegar Ind.* **8,** 14–8(1928); cf. *C. A.* **22,** 3000.—There is given for each variety of apples the date of picking, date of analysis, reducing sugar, sucrose, total sugar, acid as malic, astringency, tannin, non-tannins, total solids and acid-astringency-sugar ratio. "The analytical results lend confirmation to the conclusion established by previous work that climatic conditions during the period of development and maturity produce consistent and sustained effects upon the chem. compn. of the fruit of apple trees, the character of these effects being that of mass responses given by large groups of trees of dissimilar origin, adaptation to local conditions and character of fruit." "Since the climatic conditions of the yrs. in which the analysis were made are definitely known, and their specific effects upon the compn. of their resp. crops have been detd. for large groups of varieties, any individual analysis has somewhat greater significance than would be the case were it not accompanied by such information. J. A. Kennedy

More products and by-products from the cider mill. Carl R. Fellers. Mass. Agr. Coll. & Expt. Sta. *Fruit Products J. and Am. Vinegar Ind.* **8,** 10–3(1928).—Apple varieties for jelly, the use of culls, extg. and concg. the juice, finishing the jelly, valuable hints on handling and processing the fruit are discussed. J. A. K.

Factors in the preservation of cider. S. Henry Ayers, H. A. Barnby and E. L. Voight. Res. Lab., Glass Container Assocn. *Glass Container* **7,** No. 11, 7–40(1928).—The use of vacuum proved beneficial in reducing mold growth in cider. Yeasts were not affected by vacuum. With 3 heat-resistant species of mold previously isolated from spoiled pasteurized cider, it was detd. that a temp. of 145° F. in the cider for 45 min. or 150° F. for 15 min. would destroy the molds. However, when mold spores were on the inner surface of the neck of the container a temp. of 170° F. for 30 min. was required if the bottles were upright or 165° F. for 30 min. if the containers were placed on their side. Agitation of containers during pasteurization is urged as a possible means of overcoming the cooked taste in pasteurized cider. Bottle caps, steamed for 5 min., were rendered mold free. C. R. Fellers

Processing feeds. A study of certain processes for fermenting or enzymating feeds. A. E. Perkins and C. F. Monroe. Ohio Agr. Expt. Sta., *Bimonthly Bull.* **13,** 163–9 (1928).—Com. processes claiming to break down crude fiber or cellulose into simpler and more useful forms of carbohydrates are shown to be of little or no value in increasing the digestibility of corn stover, straw or hay. The process consists in soaking and steaming the feed, adding a "converter" or diastatic enzyme and maintaining a temp. of from 120 to 160° F. for some time. Chem. and feeding tests on rats, horses and dairy cows failed to indicate any appreciable change in compn. or feeding value. The fiber of feeds is not broken down and any increase in sugar, even when obtained, is offset by a corresponding loss of equally valuable starch. There is no suggestion or indication that any significant improvement occurs in the protein, fat, minerals or vitamins of the feeds treated by the process. C. R. Fellers

Mineral content of pastures. B. C. Aston. New Zealand Dept. Agr. *New Zealand J. Agr.* **36,** 22–7, 75–82(1928).—As a result of 77 analyses of red and white clover and cocksfoot grass pastures on pumice soil A. concludes that there is a serious

deficiency of Fe. The "pining" or nakuruitis disease of sheep pastured on pumice soils is shown to be due to Fe deficiency which can be corrected by iron licks or medicinal treatment with $NH_4FeC_6H_5O_7$. C. R. Fellers

Feeding trials with milch cows using ammonium acetate as a substitute for protein foods in agricultural practice. H. Bareiss. *J. Landw.* **75**, 265-324(1928).—In agreement with the work of Pasch it was found possible to replace 25% of the digestible protein in a ration with NH_4 acetate with no ill-effect on the cow. Normal live-weight increases in the animals occurred. There was a slight decrease in milk yield, but corresponding increase in the fat content. The utilization of NH_4 acetate by the animal takes place in conjunction with the amides present in the other food material. B. C. A.

Behavior of fats and oils in ultra-violet light (Haitinger, *et al.*) **27.** Changes produced in meat extracts by the bacterium *Staphylococcus aureus* (Foreman, Smith) **11C.** Food value of the potato for white rats (Galamini) **11E.** Nutritive value of alba blood as a source of protein (Hauge) **11E.** Apparatus for drying cereals (Brit. pat. 283,717) **1.** Albuminoids (Brit. pat. 283,866) **17.** Paper pulp [feeding stuff produced in manufacture of] (Brit. 283,857) **23.**

Flour. Cornelius Massatsch and Eugen G. Cluss (to Matro G. m. b. H.). Canada 282,505, Aug. 14, 1928. A flour suited for human food and for dietetic purposes is prepd. from root germs of grain or maize from malting processes by treating the germs preliminarily at a mild heat with a quantity of a dil. alkali soln. (potash or caustic alkali) corresponding to the soaking capacity of the germs, removing the germs from the liquid, drying and grinding them to a powder or flour and mixing this flour with another flour or other addns.

Milk treatment. Alfred W. Bosworth and Lewis H. Chrysler (to A. W. Bosworth). Can. 282,737, Aug. 21, 1928. Part or all of the Ca is removed from the milk, by removing the fat from the milk, then adding a substance contg. the phosphoric acid radical in amt. insufficient to coagulate or ppt. the casein, rendering the milk slightly alk. (by addn. of soda, potash or ammonia either caustic or carbonate) whereby the Ca present is converted into insol. Ca phosphate, which is pptd. in the form of a gel and sepd. by filtration or centrifugation, and thereafter neutralizing any undesired excess of alkali in the milk.

Packing acidophilus milk powder. Raphael S. Fleming (to Merrell Soule Co., to The Borden Co., to Merrell-Soule Co., Inc.). Can. 282,507, Aug. 14, 1928. Acidophilus milk powder packed in cans is subjected to vacuum immediately after production to reduce the free or uncombined O in the cans to less than 5 cc. per lb. of powder and preferably less than 3.5 cc. and the cans are then charged with a gas, as CO_2 or a combination of gases as CO_2 and N, which do not contain free or uncombined O and thus preserve the *Bacillus acidophilus* organisms. Cf. *C. A.* **22,** 286.

Separating butter fat from buttermilk and buttermilk whey. Arthur L. Rushton (one-half to Munson H. Lane). U. S. 1,683,728, Sept. 11. Material such as sour cream buttermilk is treated with a reagent such as NaCl or NaOH which materially reduces the clogging tendency of casein in the buttermilk when centrifuged and is then centrifuged in a cream separator for a longer time than required in ordinary cream sepn.

Recovering butter fat from buttermilk. Arthur L. Rushton (one-half to Munson H. Lane). U. S. 1,683,729, Sept. 11. Buttermilk or buttermilk whey is subjected to a centrifugal sepn. at approx. the same speed that is used for sepg. cream from whole milk and the fluid recovered from the cream outlet of the separator is then subjected to another sepn. by passing it through a cream separator at a lower rate than used in treating whole milk; "buttermilk cream" is recovered from the cream outlet and is churned to make butter.

Ice cream. James R. Hatmaker. U. S. 1,684,094, Sept. 11. A portion of a given quantity of natural whole milk is dried and the dry solids thus obtained are then incorporated with the remainder of the original quantity of milk, and mixed with addnl. cream and stabilizing and flavoring substances, to form a mixt. for making ice cream.

Treating cereals. Ludwig Bartmann (to The Treuhand-Ges. m. b. H. Bartmann & Co.). Can. 282,539, Aug. 14, 1928. The grains of the cereal are steeped at 30-40° in H_2O until the endosperm has become soft and pasty while the layers surrounding the same have assumed a tough and leather-like character. At the same time grains are treated with CH_2O to paralyze the germs of embryos and thereafter pressure is applied

to cause the outer layers to burst and the endosperm to be expelled in a substantially pure state. Cf. *C. A.* **22**, 3243.

Composition for preserving eggs. HENRY STANLEY. U. S. 1,683,631, Sept. 11. A mixt. adapted for coating the shells of eggs is formed from wheat bran 92.76, NaCl 7.01 and mineral ocher 0.23%.

Preserving meat. W. H. HOBBS and A. LANE. Brit. 283,626, Oct. 11, 1926. Meat is stored in a closed chamber at a temp. of about 0° in air of a humidity of 62–66% which had been bubbled through a soln. of thymol in HOAc. The meat may be preliminarily washed with HOAc soln. An app. is described.

Preserving fish and other animal foods by packing in moistened sphagnum. W. K. GÜNTHER. Brit. 284,130, June 7, 1927. Salt water may be used for dampening the sphagnum.

Drying plant for fish and other foods. L. S. TOFTDAHL. Norw. 44,176, June 27, 1927. Mech. features.

Pectin. A. LEO. Brit. 283,657, Oct. 18, 1926. A sol. compn. for jellifying jams, jellies, fruit juices, etc., is made by treating pectin or a pectinous material with citric acid or other suitable weak edible acid and partially neutralizing (preferably with $NaHCO_3$) so that gas is evolved which assists in the soln. of the pectin.

Desiccating fruit juices, etc. E. JAMESON, E. D. STEWART and C. P. WILSON (to California Fruit Growers Exchange). Brit. 283,579, Jan. 15, 1927. A product in powd., granular or flake form is prepd. by spray desiccation of juices such as those of oranges, lemons or grape fruit admixed with lactose, with or without addn. of other sugars. Brit. 283,580 specifies admixing the juice with colloids such as pectin, agar or gelatin, with or without lactose or other sweetening or flavoring substances, and spray desiccating the mixt. Brit. 283,581, C. P. Wilson and E. D. Stewart (to California Fruit Growers Exchange) specifies spray desiccation of mixts. of fruits juices with milk.

Apparatus for concentrating fruit juices. ARNOLD BECKE. Austrian 108,689, Sept. 15, 1927. Hot air is bubbled through the juices and a steam-heated coil is arranged in the air space above them.

Separating thistle buds from peas by flotation in a hot water bath. OGDEN S. SELLS (to Sprague-Sells Corp.). U. S. 1,683,703, Sept. 11.

Cattle food. PHILIP R. PARK (to The Park and Pollard Co.). Can. 283,290, Sept. 11, 1928. A cattle food contains a cereal body and dried fish scrap having I-bearing oil dispersed therein in growth-stimulating proportions.

Fodder. ALBERT E. KIENZLE (to Soc. anon. des Bières Bomonti et Pyramides). Can. 282,526, Aug. 14, 1928. An animal fodder contains 50% Indian corn-cob flour to 50% sugar-cane flour (coarse) with the exclusion of fine sugar cane flour dust. Cf. *C. A.* **22**, 2220, 3003.

Cattle fodder. EMIL R. J. SCHRÖDER. Norw. 44,411, Sept. 26, 1927. Two parts of fresh ground sea-weed are mixed with 1 part of waste flour and the mixt. is stirred with water of 70° to a stiff pulp. After being stored for 5 hrs. the mass is pressed and dried to fodder cakes or the pulp is passed through a rotary drying cylinder and ground to fodder meal.

13—GENERAL INDUSTRIAL CHEMISTRY

HARLAN S. MINER

Research and chemical industry. FRANCIS H. CARR. *J. Soc. Chem. Ind.* **47**, 249–55T(1928).

Research and profits. C. S. MINER. Miner Labs., Chicago. *Ind. Eng. Chem.* **20**, 1069–71(1928).
E. H.

The industrial applications of ultra-violet rays. J. J. TRILLAT. *Science & industrie* **12**, No. 168, 27–32(1928); cf. *C. A.* **21**, 3018.
E. H.

Seventh (French) congress of industrial chemistry. MAURICE DESCHIENS. *Chimie et industrie* Special No., 1–72(April, 1928).—A detailed account of the proceedings.
A. PAPINEAU-COUTURE

The problems of the organic chemical industry. H. E. FIERZ-DAVID. École Polytechnique, Zurich. *Chimie et industrie* Special No., 109–20(April, 1928).—An address indicating the directions in which various branches of the org. chem. industry are developing.
A. PAPINEAU-COUTURE

Crystallization from quiet and from agitated solutions. KARL KIEFER. *Chem. App.*

15, 185–6(1928).—A discussion of the currents in crystg. solns. caused by difference in temp. and d. due to deposition of crystals. With quiet solns. it is of the utmost importance to find the most suitable d. for the production of the largest amt. of wall crystals. With agitated solns. the d. must be found at which the so-called "growth curve" runs parallel with the "deposition curve." This point differs with every soln. and must be detd. by expt. The temp. drop in the crystallizer by which the curves run parallel differs with most solns., being about 5° with some, and to get the best results large vols. of soln. should pass through the crystallizer. Methods for the detn. of these curves are not given. J. H. MOORE

Distillation and rectification under reduced pressure and their applications. A. FICHOUX. *Chimie et industrie* Special No., 292–307(April, 1928).—A discussion of accepted exptl. facts and present-day theories with examples of their application for the selection of the most suitable type of equipment under given conditions (dyestuffs intermediates industry, petroleum products, recovery of C_6H_6 or gasoline from scrubbing oils, recovery of glycerol from distillery vinasses, rectification in vacuum of mixts. which are azeotropic at atm. pressure). A. PAPINEAU-COUTURE

Investigation of the capacity of the evaporating surface and the steam space of steam boiler and evaporating apparatus. CHR. EBERLE. *Arch. Wärmewirt.* 9, 282–3 (1928).—The quality of the steam produced by a boiler at pressures from 1 to 10 atm. was found to depend on the vol. of steam evolved per hour, not on its wt. The moisture in the steam became appreciable at a certain crit. vol., and rose rapidly and linearly thereafter. ERNEST W. THIELE

A method for determining the percentage of water in steam. ROBERT AVICE. *Rev. agr. Maurice* 5, 124–5(1928).—A sampling pipe of 1 in. diam. and perforated in several places is mounted into the steam line in such a way that samples may be taken at any desired moment. A weighed quantity of H_2O is placed in a convenient receptacle, and the steam from the sampling pipe passed through it for several min. The receptacle is reweighed, and the % of dry steam q may be calcd. from the following formula: $W(T_2 - T_1) = W_1(qL + (T_3 - T_2))$, where W is the original wt. of the H_2O, W_1 the wt. of the condensed steam, T_1 the initial temp. of the H_2O, T_2 its final temp., T_3 the temp. of the steam, and L the latent heat of the steam. For greater accuracy, the heat absorbed by the receptacle must also be considered; then the formula changes to: $(W + SW_2)(T_2 - T_1) = W_1(qL + (T_3 - T_2))$, where W_2 is the wt. of the receptacle, and S the sp. heat of the material from which it is made. A "Throtting Calorimeter" may be used for the same purpose as the method described, but it is expensive. F. W. ZERBAN

New Jersey's experience with benzene poisoning. ANDREW F. MCBRIDE. *Am. Dyestuff Rept.* 17, 558–60(1928).—Chronic poisoning may occur among workmen exposed to atms. contg. as little as 1 part C_6H_6 in 10,000. The practical directions, for avoiding chronic C_6H_6 poisoning, formulated by the Industrial Poisons Comm. of the Nat. Safety Congress, are quoted. So far as possible toluene, xylene, Et acetate and other relatively harmless solvents should be substituted for C_6H_6. L. W. R.

Kraemer-Sarnow method [for determining the softening point of pitch] and mercury poisoning. H. MALLISON. *Z. angew. Chem.* 41, 839–40(1928).—The danger of chronic poisoning by prolonged contact with Hg has been pointed out by Stock and others; it is therefore suggested that the Hg method of detg. the softening point of pitch should be universally replaced by the American "ring and ball" method. B. C. A.

Physiology of breathing in industrial masks. I. The comfort of the individual in the use of masks. E. HÖRNICKE AND O. BRUNS. Univ.-Poliklinik zu Königsberg. *Z. ges. exptl. Med.* 56, 98–117(1927).—Masks with the canister attached direct, and with the canister connected to the mask with a tube were studied. The pressure variation due to the filter increased with usage and varied with different individuals but had no serious effects. Increasing the dead space increased the min. vol. both in rest and during activity. There were no serious changes in pulse or blood pressure. The discomfort is related to the amt. of dead space. F. L. DUNN

Modern methods of insulation. I. S. CAMMERER. *Chem. Fabr.* 1928, 341–2.—Approx. data are given for the economical degree of insulation for varying pipe diams. and temp. differences. For the accurate detn. of the efficiency of insulating materials the Schmidt method employs an auxiliary surface consisting of a rubber sheet of given dimensions provided on both surfaces with a large no. of thermoelements. This is laid on one side of the material to be tested. A recording millivoltmeter is of great assistance, providing a continuous record of heat loss. B. C. A.

Insulation against heat and cold. I. S. CAMMERER. *Chem. Fabr.* 1928, 318–20.—Estimates of thermal losses from steam pipes, etc., with and without insulation are

given. All insulating materials depend for their properties on a porous structure with air spaces, but if such spaces are not quite small convection currents are set up. Qualities desirable for insulating materials for various purposes are described. While a variety of inorg. and org. materials are used for heat insulation, only cork and peat have hitherto found much application for cold-storage insulation. Practical tests are particularly valuable in choosing an insulating material. B. C. A.

The mechanism of exchanges in distilling and rectifying equipment (MARILLER) **2.** Graphical method for determining the course of the natural distillation process (BRANDES) **2.** Glass [for insulating purposes] (U. S. pat. 1,684,332) **19.** Synthetic resins [for insulating] (Brit. pat. 283,803) **26.**

Pitman's Technical Dictionary of Engineering and Industrial Science, in Seven Languages—English, French, Spanish, Italian, Portuguese, Russian and German. In 2 parts, edited by Ernest Slater. London: Sir Isaac Pitman & Sons, Ltd. Part I and Part II each 2s. 6d. Reviewed in *J. Roy. Soc. Arts* **76,** 982; *Intern. Sugar J.* **30,** 496(1928).

Purifying distillation gases. J. BECKER (to Koppers Co.). Brit. 283,948, Jan. 22, 1927. Fouled purifying material such as that used in treating gases from coke ovens employed in connection with a steel plant is regenerated by treatment with combustible gas, *e. g.*, a portion of the purified gas, which may then be burnt under the coke ovens. Various app. and details are described. Cf. *C. A.* **22,** 1814.

Carrying out gas reduction processes. EMIL EDWIN. Norw. 40,145, Dec. 27, 1927. Steam is added to the gas and its content of CO is partly or completely converted into CO_2 and H_2. Or, only a part of the total circulating gas quantity is taken out and subjected to the said treatment and again returned into the process. The CO_2 formed is recovered.

Closed-circuit system for adsorbing and subsequent recovery of gases or vapors. NORIT-VEREENIGING VERKOOP CENTRALE. Brit. 283,508, Jan. 11, 1927. An app. is described.

Recovering volatile solvents. HERMANN BOLLMAN. Ger. 451,906, Nov. 21, 1927. Volatile solvents such as C_6H_6, benzine, ether and alc. are recovered from mixts. of the solvent vapor and air by atomizing the mixt. together with a fatty oil or fatty acid into a cylindrical container provided with a tangential atomizer. The droplets of oil carried along with the liberated air are pptd. by causing the air to pass out over a helical baffle. The solvent is then distd. from the oil or acid.

Boiling down liquids evolving volatile constituents. AKTIENGESELLSCHAFT KUMMLER & MATTER. Ger. 451,973, Nov. 21, 1927. Liquids such as *sulfite liquor* are concd. by condensing the vapors and again using the condensed vapors as dry steam, which is sprayed into the heating chamber together with an excess of finely divided hot water. Condensate from the heating chamber may be used as the hot water.

Colloidal suspensions. A. BIDDLE. Brit. 283,686, Nov. 15, 1926. See Can. 270,571 (*C. A.* **21,** 3430).

Refrigerating apparatus of the continuous-cycle absorption type. PLATEN-MUNTERS REFRIGERATING SYSTEM AKTIEBOLAG (to Electrolux, Ltd.). Brit. 283,937, Jan. 20, 1927.

Refrigerating apparatus of the absorption type. A. LENNING (to Electrolux, Ltd.). Brit. 283,473–4, Jan. 8, 1927. Structural features.

Refrigerating apparatus of the absorption type. A. LENNING (to Electrolux, Ltd.). Brit. 283,938, Jan. 20, 1927. Structural features.

Refrigerating apparatus of the absorption type. STUART OTTO (to Iceless Automatic Refrigerator Co.). U. S. 1,684,196, Sept. 11. Structural features.

Refrigerating apparatus of the absorption type. IVAR AMUNDSEN. Norw. 44,261 and 44,262, Aug. 1, 1927. The cooling is produced by means of an active gas-adsorbing substance which alternately adsorbs and gives off the cooling fluid, which may be a gas or a liquid. The active substance can be silica gel, bleaching earth or active carbon,

a suitable substance being animal carbon from bones or blood for instance the Merck's Carbo Medicinalis. The cooling fluid can be NH_3, SO_2, CH_3Cl, C_2H_5Cl or an alc., preferably methanol or ethanol.

Controlling the hardness of baked insulating material such as enamel on wire. EGIDIO E. MANESCHI (to Western Elec. Co.). U. S. 1,683,833, Sept. 11. The amount of baking to which the material is subjected is regulated in accord with a detn. of dielec. losses in the material when subjected to an alternating electrostatic field. An app. is described.

Insulating material. JOSEPH M. COFFEY (to The Mica Insulator Co.) Can. 283,428, Sept. 18, 1928. An insulating material is composed of thin mica splittings and phenol-glycerol resin binder in the proportion 95 and 5% by wt. The material when hot is capable of being molded into shapes and retaining such shapes when cooled.

Heat-insulating material. WILLIAM K. NELSON (to Insulex Corp.) Can. 283,061, Sept. 4, 1928. A heat-insulating material of cellular texture contains 2 lb. calcined gypsum, 3 oz. $Al_2(SO_4)_3$, 1.5 oz. $CaCO_3$, 4 g. soap, 8 g. talc, finely ground and thoroughly mixed and having added thereto 26 liquid oz. H_2O. The CO_2 evolved within the mass forms a bubble-producing medium. Cf. *C. A.* **22**, 3006.

14—WATER, SEWAGE AND SANITATION

EDWARD BARTOW

Sixty-first annual report of the Commissioners of Water Works in the City of Erie, Pa., for year ending December 31, 1927. 84 pp.—Extensive tabulations of financial data and operating statistics are given. Av. daily consumption during the year was 24,088,683 gallons, equiv. to 192.7 gallons per capita to estd. population supplied of 125,000. The cost of collecting, purifying and distributing the water, including depreciation, was $23.168 per million gallons. The amt. of water pumped per lb. of coal consumed averaged 279 gallons. The av. amts. of alum and hypochlorite used were 0.145 grains per gallon and 3.1 lb. per million gallons, resp. The wash water averaged 1.82% of the water filtered. Of 300 1-cc. samples of raw water examd. for *B. coli*, 63 showed positive results, while of 599 10-cc. samples of filtered water examd. none contained the colon bacillus. A brief description of the water-purification works is included. R. E. THOMPSON

The design and equipment of water-works laboratories. MELVILLE C. WHIPPLE. *J. New Eng. Water Works Assoc.* **42**, 339–55(1928).—Detailed suggestions, including location, layout of space, equipment, app. and library. D. K. FRENCH

Present practice in water-meter construction. DENKERT. *Gas u. Wasserfach* **71**, 778–84, 804–9(1928).—Present-day construction of water meters, resistance to corrosion and materials of construction as well as the working range of German water meters are discussed in detail, with illustrations. R. W. RYAN

The role of water in hygiene. F. BOURGUIN. *L'Eau* **21**, 92(1928).—A general presentation. C. R. FELLERS

The chemico-sanitary investigation of water with regard to organic substances. L. M. HOROWITZ-WLASSOWA, A. M. AND F. M. GOLDENBERG. *Arch Hyg.* **98**, 234–40 (1927).—An investigation was made of river water, of infusions of dry and green leaves, and of various solns. of proteins, fats and carbohydrates. Similar values obtained by Kubel's reaction for the oxidizability of the solns. did not correspond to identical content of organic matter. A 0.01% soln. of glucose takes up in 10 min. only 75% of the calcd. amt. of O; peptone under the same conditions scarcely 25.5%. The method of Fowler is of greater value from a sanitary point of view, since org. material of animal origin is more rapidly detd. by this method. P. Y. JACKSON

Bacterial results following a failure to sterilize new water mains. W. M. OLSON AND H. L. WRIGHT. *J. Am. Water Works Assoc.* **20**, 229–33(1928).—While no serious disease followed, the water was complained of as undrinkable, and bacterial count was very high. D. K. FRENCH

The d'Herelle bacteriophage in drinking water. PAUL FABRY. *Rev. Hyg. Med. Prev.* **50**, 667–71(1928).—The presence of the colon bacillus in water must be considered with suspicion. On the other hand its absence may not indicate pure water because the organism may have undergone lysis by the bacteriophage and could not be recovered by ordinary lab. methods. If a bacteriophage is found in water, this may indicate, *per se* intestinal pollution. C. R. FELLERS

Water-supply struggles of a small southern city. PRESON P. PHILLIPS. *Eng.*

News-Record **101**, 361–3(1928).—The recently completed water works of Mount Airy, N. C., treating water drawn from Lovill's Creek, consists of a mixing chamber, 2 coagulation basins, three 0.5-million gallon rapid sand filters and a 0.5-million gallon clear well. The plant, which is of 1.5-million gallons capacity, will provide 200 gallons per capita daily to the present population of 7500. The mixing basin, which is of the over-and-under baffled type, provides a retention period of 15 min., and the 2 coagulation basins 5 hrs. The cost of the plant was approx. $140,000. R. E. THOMPSON

Conserving water supply at Springfield, Mo. WM. J. GRAY. *Eng. News-Record* **101**, 128(1928).—Waste reduction activities in Springfield are outlined. The water supply is at present derived from springs and wells, and an impounding reservoir is under construction on the North Sac River. The purification plant consists of a sedimentation basin, an 8-million-gallon filter plant and chlorination app. R. E. T.

Expansion of the municipal waterworks at Bologna. A. NATALE. *Gas. u. Wasserfach* **71**, 799–804(1928).—Details of the expansion of the Bologna waterworks are given and especial attention given to the methods of adding lime and alum as well as filtering. R. W. RYAN

The water supply of Caracas, Venezuela. THORNDIKE SAVILLE. *J. New Eng. Water Works Assoc.* **42**, 303–38(1928).—The present supply is from rivers and creeks. *B. coli* are practically always confirmed in supply samples and the water at no time would pass the U. S. Pub. Health Standards. Sterilization following sedimentation has been recommended. D. K. FRENCH

Some recent improvements in the softening of natural waters. P. PATIN. *Chimie et industrie* Special No., 158–62(April, 1928).—A description and discussion of water-softening by means of base exchange with artificial zeolites. A. PAPINEAU-COUTURE

Water softeners and water softening. W. L. ASHMAN. *Gas. Eng.* (London) **44**, 42; *J. Am. Water Works Assoc.* **20**, 157.—A general résumé from the impurities causing scale to the latest methods of removal. D. K. FRENCH

An outline of water softening. J. F. PIERCE. *Am. City* **30**, No. 3, 90–1(1928).—The zeolite process is outlined, with particular reference to its applicability to small community softening problems. E. M. S.

The filtration and treatment of water for domestic purposes. ALEXANDER C. HOUSTON AND HENRY E. STILGOE. *Water and Water Eng.* **30**, 357–62(1928). J. A. KENNEDY

Filter operation at variable rates. HARRY N. JENKS. *J. Am. Water Works Assoc.* **20**, 214–9(1928).—Overloading shortens the possible hrs. of operation of the filter because of premature clogging, but within proper limits operation at variable rates does not impair the quality of the effluent. Beyond fairly well-defined limits, however, overloading results in a marked decrease in efficiency. D. K. FRENCH

Filterplant troubles traced more often to faulty design than to poor operation. C. A. BROWN. *Hydraulic Eng.* **4**, 89, 102–4; *J. Am. Water Works Assoc.* **20**, 159 (1928).—The ideal plant is suggested and described. D. K. FRENCH

Zeolite filter plant of Ohio Valley Water Company, Bellevue, Pa. A. H. KNEEN. Pa. Water Serv. Co., Wilkes-Barre. *Ind. Eng. Chem.* **20**, 951–3(1928).—The wells are located in the gravel deposits of the Ohio River. The well water is clear and ample in quantity, but is hard and contains Mn and *Crenothrix*. The capacity is about 6 m. g. d. Complete details for the 4-unit softening plant and its operation are given. J. A. KENNEDY

Chemical handling and control of the Baltimore filters. JAMES W. ARMSTRONG. *Eng. News-Record* **101**, 65–6(1928).—The methods of chem. control employed at the Montebelo filter plants, Baltimore, are described. The new and old plants, of 128 and 112 million gallons capacity, resp., adjoin each other. Alum is used as coagulant and is manufactured at the works from bauxite and H_2SO_4. The process employed is outlined and the automatic app. used for controlling the application of the resulting alum soln. to the water is described. Lime is added to the filtered water to reduce CO_2 and prevent corrosion, the amt. required being detd. by the p_H value of the water. The control app. is similar to that employed for the alum. R. E. THOMPSON

Experiences with the Norit filter in tropical countries. J. W. WOLFF. *Geneeskund. Tijdschr. Nederland. Indië* **68**, 171–82(1928); cf. Wolff, *Centr. Bakt. I. Orig.* **101**, 163(1927).—When used for the filtration of clear well water the Norit filter yielded sterile water at a rate 1–2.5 l./hr. One Norit filling may last 6 months. Turbid, heavily contaminated river water soon clogs the pores of the chamber which serves for the retention of the coarse impurities. MARY JACOBSEN

New pumping and filtration plant for Knoxville water works. CHAS. B. BURDICK. *Eng. News-Record* **101**, 204–7(1928).—An illustrated description of the new Williams

Creek plant treating Tennessee River water. The population supplied is 100,000 and the consumption 9 million gallons per day. The plant consists of two 36-in. intake pipes, 2 circular mech. mixing chambers, 2 coagulation basins providing 6 hrs.' retention at the rated capacity of 15 million gallons per day, and six 2.5-million-gallon rapid sand filters. Alum and occasionally lime are employed in treatment. R. E. T.

Filter plant provides public square and bath houses. PAUL HANSEN. *Eng. News-Record* **101**, 87–8(1928).—An illustrated description of the new water-purification plant at Kenilworth, Ill., on Lake Michigan. It replaces the old pressure filters, which did not at all times effect satisfactory removal of turbidity. The plant, which has a nominal capacity of 1 million gallons per day, consists of mixing and coagulation basins, 2 filters and clear well. Provision was made for a 30-min. mixing period to facilitate removal of the microörganisms that occur in the lake water in certain seasons. The population is 2500. R. E. THOMPSON

Effect of liquid-chlorine application to trickling filters. T. C. SCHAETZLE. *Bull. Md. State Dept. Health* **1**, 87–96(1928); *Pub. Health Repts.* **43**, 2285–6(1928).—The settled sewage flowing to a trickling filter located in the suburbs of Baltimore was chlorinated to det. the effect upon the *Psychoda* the trickling-filter fly, which was present in large nos. in the filtering material, and to ascertain the resulting effect upon the nitrifying powers of the trickling filter of such chlorination. Cl doses of from 5.0 p. p. m. and 10.0 p. p. m. were used. Such chlorination did not destroy the larvae of *Psychoda*, although the adult fly was killed by direct contact with the chlorinated sewage. The chlorination of the sewage resulted in the removal of the growth of the stones in the immediate vicinity of the nozzles. Very little reduction in the nitrifying power of the bed was observed during 5.0 p. p. m. dosing and a greater but not abnormal denitrification resulted during the application of 10.0 p. p. m. Cl. The nitrifying powers of the trickling filters began to return to an approx. normal condition within about 4 hrs. after the Cl application was stopped. The filter effluent contained residuals of between 0.2 p. p. m. and 1.33 p. p. m. Cl, during 1 complete cycle of the dosing siphon. C. R. FELLERS

Influence of free chlorine on the elimination of manganese from water. O. WEBER. *Chem.-Ztg.* **51**, 794–5(1927).—The elimination of Mn from H_2O by aeration and filtration of the oxidized Mn compds. depends not so much on chem. action as on biol. influence. Tabulated results from a waterworks in Hanover show that the Mn content is not lessened by aeration and filtration when free Cl is added to the raw water; considerable improvement is seen when the Cl is added after filtration, but the Mn is entirely eliminated only when unchlorinated raw water is used for washing the coke filters. A filter requires time to attain its highest efficiency, and its MnO_2 content is important. B. C. A.

Water sampler for the determination of dissolved oxygen. JACK J. HINMAN, JR. *J. Am. Water Works Assoc.* **20**, 253–6(1928).—A very clever and seemingly foolproof device is described. The sampling bottle passes more than 10 times its capacity before the device stops operating. D. K. FRENCH

Biochemical oxygen demand. LEROY FORMAN. *Public Health News N. J. State Dept. Health* **13**, 132–6(1928); *Pub. Health Repts.* **43**, 2227–8(1928).—Several series of expts. were made in an attempt to secure uniform and consistent results in the detn. of biochem. O demand. Tests were made to det. the effect of using different temps. for aeration of dilg. H_2O, the effect of aging dilg. H_2O, the temp. of incubation, the effect of using distd. or Trenton tap water, and the effect of adding salts to increase the p_H. Some of the conclusions are: That all factors must be controlled; aged tap water is satisfactory at any one plant, but for comparison of results with other plants a uniform dilg. water is necessary; the nature of the material is considered a less important factor than formerly; the greatest factor for obtaining good results in detns. of biochem. O demand are (1) mineralized water, preferably with potash salts, with a p_H well on the alk. side; (2) well aged dilg. water and (3) incubation at a uniform temp. and not below 20°. A modified procedure adopted by the New Jersey State Department of Health is presented. C. R. FELLERS

Titration of carbon dioxide in water. L. SMITH AND G. WODE. *Z. angew. Chem.* **41**, 208–12(1928).—See *C. A.* **21**, 3997–8. H. G.

Determination of available sulfur in mineral waters. CHARLES LEPIERRE. Inst. Sup. Technique et Inst. d'Hydrologie, Lisbonne. *Chimie et industrie* Special No., 131–2(April, 1928).—Available S is defined as that present as H_2S, XHS or X_2S. Because of lack of sensitiveness of ordinary methods of detn., absence of available S has often been reported in mineral waters in which it could be detected by smell. Detn. by production and colorimetric detn. of *thionine* gives accurate results for amts. varying

from a few mg. to a few 0.01 mg. S per l. The following technic is recommended: to a suitable amt. of water (up to 2 l.) add 1 cc. concd. HCl, then 0.05 g. *p*-phenylenediamine, and finally 0.2 cc. of 10% $FeCl_3$, mix, heat to about 60°, let stand until the color has reached max. intensity (about 15–20 min.) and compare with a standard thionine soln. Commercial thionine can usually be used for prepg. the standard soln.; but if the shade differs appreciably from that obtained with the sample, a soln. of H_2S should be standardized iodometrically, suitably dild. and treated as above. The reaction is specific, being unaffected by sulfites, thiosulfates or the alky. of the water.

A. PAPINEAU-COUTURE

Stuart, Florida, iron-removal and pumping station. P. P. DEMOYA. *J. Am. Water Works Assoc* **20,** 244–52(1928).—Aeration to reduce CO_2 and upward filtration through gravel is considered to give a satisfactory water. The plant and the theory of operation are described fully. D. K. FRENCH

Coördination of biological and chemical work in the investigation of polluted waters. DAVID ELLIS. *Ind. Chemist* **4,** 291–4(1928).—The chemist's field and the bacteriologist's field in the examn. of drinking water are sep. and distinct. The albuminoid-NH_3 test does not always show a correlation with the no. of bacteria. This is the case also with the "oxygen absorbed." Black mud is not necessarily an indication of sewage pollution. Bacteria in the black mud of the Clyde liberate H_2S which produces black FeS from the Fe compds. present. This black mud continues far beyond the zone of any possible sewage contamination. *Cladothrix dichotoma* and *Crenothrix polyspora*, members of the group of iron bacteria, may cause a reservoir for weeks on end to resemble a muddy, dirty pond. They flourish best in water from boggy or marshy ground. If present, the gathering ground for the water needs attention. E. G. R. ARDAGH

Economical treatment of swimming pool waters. LEWIS O. BERNHAGEN. *Proc. 10th Texas Water Works Short School* **1928,** 150–5; *Pub. Health Repts.* **43,** 2226(1928).—There is a discussion of the 3 general types of pools, namely, the fill-and-draw, the flowing-through, and recirculation pools At Beaumont, Tex., water was supplied to a flowing-through pond by a well at slightly less than 5¢ per 1000 gals.; air-lift pumping equipment was used, air being supplied by a compressor operated by a 20-h. p. motor with power cost of 3¢ per kw. hr. However, as most wells put down at a moderate cost cannot be depended upon for an unfailing supply, a hypothetical example of comparative costs for a 600,000-gal. pool is worked out, with itemized estimate of initial cost and operation of recirculation pool with filtration and disinfection, and operating cost of flowing-through pool. It is estd. that the former will give a 51% return on the initial investment of $6500 over that of the latter method. The enforcement of soap and water cleansing of bathers prior to use of a pool, the importance of water temp. not exceeding 72° F., and the advantages of Cl compds. over ultraviolet ray disinfection are pointed out. C. R. FELLERS

Adaptability of sodium aluminate in water treatment. P. W. EVANS. *Proc. 10th Texas Water Works Short School* **1928,** 134–42; *Pub. Health Repts.* **43,** 2291(1928).—Four main advantages are given, as follows: (1) Increased plant capacity or output due to more rapid clarification of settling; (2) less causticity, which should, in turn, result in reduced trouble from foaming; (3) the avoidance of the increase of alkali sulfates in treated water, resulting from the use of either alum or copperas; (4) the elimination or material reduction in the amt. of after-ppts. which will result in (*a*) reduced trouble of pipe lines, heaters, branch pipes and injectors becoming clogged; (*b*) a material reduction in foaming troubles; (*c*) a decided reduction in the no. of boiler washings. Chem. reactions involved are discussed at length. C R. FELLERS

Treatment of Missouri River water for locomotive use. H. H. RICHARDSON. Mo. Pac. R. R. Co., St. Louis. *Ind. Eng. Chem.* **20,** 924–5(1928).—Lime-soda ash water-softening plants have been installed at 10 points where Mo. River water is used. Untreated city water is being used at 3 other points. Na aluminate is used in all but 2 of the plants where the water is being treated. Statistics and further details of operation are given. J. A. KENNEDY

Progress report of the boiler feed water studies committee. *Fuels and Steam Power, Am. Soc. Mech. Eng. Trans.* **50,** 213–4(1928).—Formerly feed water treatment meant only removal of scale. Such equipment is now in use. Deaeration minimizes corrosion troubles in boilers, but corrosion in the absence of O_2, formation of H_2 and O_2 by direct ionization of pure H_2O, embrittlement of boilers at relatively low pressures, are new problems brought up by recent developments. E. M. SYMMES

Modern practice in boiler feed-water purification. G. E. FOXWELL. *Gas World*

89, Sept. Coking Sect. 10–4(1928).—A review and discussion of causes and methods of prevention of scale and corrosion. F. S. GRANGER

Lime-soda diagram as aid in feed-water treatment. I. W. ARBATSKY. *Warme* **50,** 329–53; *J. Am. Water Works Assoc.* **19,** 230(1928).—Hardness tests and titrations often give misleading information as to the completeness of a feed-water treatment. Naming as "unripe" a water where reactions are deferred or incomplete, A. discusses every phase of its proper treatment. There is also described a calcg. device for lime-soda requirements as well as a quick volumetric and colorimetric method of testing. D. K. FRENCH

Elimination of oil from boiler feed water. C. N. RIDLEY. *Eng. and Boiler House Rev.* **41,** 374–6, 378; *J. Am. Water Works Assoc.* **20,** 158(1928).—After describing the mechanism of oil contamination reference is made to methods of removal, including mech., chem. and elec. D. K. FRENCH

The effect of industrial wastes on boiler-feed water problems and condenser operation. V. B. SIEMS. *Fuels and Steam Power, Am. Soc. Mech. Eng. Trans.* **50,** 223–5 (1928).—New treatments of feed water are I recarbonation of chemically softened water, II use of SO_2 for decolorization and assisting coagulation, III use of Na_2SiO_3 to stop corrosion. I is a means of preventing deposition of $CaCO_3$ in mains and incrustation of sand grains of filters where lime-soda softening is used. CO_2 gas is diffused through the water to form bicarbonates, the Ca bicarbonate dissolving. This is of use in public water supplies but is objectionable for boiler use. II has some use, but its effect on boilers has not been detd. III is applied to prevention of corrosion by brine solns. in refrigeration. In waters it would form the very harmful Ca silicate. E. M. SYMMES

Theoretical and experimental studies on the scaling of boilers. R. STUMPER. *Chimie et industrie* **20,** 10–20(1928); cf *C. A.* **21,** 3998.—A critical review of the work done on and theories proposed to explain the mechanism of the formation of boiler scale, particularly from the standpoint of the physicochem. laws governing the formation of a solid phase in solns. A. PAPINEAU-COUTURE

The heat conductivity of boiler scales. CHR. EBERLE AND CL. HOLZHAUER. *Arch. Wärmewirt.* **9,** 171–9(1928).—Heat cond. tests were made on dry compressed powders of varying densities, composed mainly either of SiO_2, $CaCO_3$ or $CaSO_4$, also on solid slabs of the 2 latter. The material makes little difference, the cond. depending almost wholly on the d. A study was made of 31 samples of scale collected at random. The $CaSO_4$ scale had always a high d., the SiO_2 always a low d., while the $CaCO_3$ was usually dense. A SiO_2 layer 0.02 cm. thick may do as much harm as a dense $CaSO_4$ layer 0.4 cm. thick. Photomicrographs of the scale, and a discussion of the possible modes of formation, are given. ERNEST W. THIELE

Fractured boiler plates. GEORGE NESS AND DOUGLAS A. MACCALLUM. *J. West. Scot. Iron and Steel Inst.* **35,** 101–9(1928).—Several cases are given of fractured boiler plates and straps, along with analyses of steel, phys. properties and analyses of scales occurring between straps and plates. Analyses of feed water and boiler water after 43 days, steaming are given. It is concluded that the origin of fractures can be traced to purely mech. causes, and that caustic embrittlement is not a necessary cause of failure. Numerous *photomicrographs of steels* are given. J. K. ROBERTS

Boiler-corrosion problems. F. N. SPELLER. *Fuels and Steam Power, Am. Soc. Mech. Eng. Trans.* **50,** 222–3(1928).—Problems for investigation are: corrosion rate and H_2 evolution in the absence of dissolved O_2 through range of acidity and alky. in general practice and 140 to 450° F.; the same with dissolved O_2 present within practical ranges; detn. of dissolved O_2 in operating boilers at different points in the boiler; detn. of H-ion concn., alky. or acidity at boiler temps. *vs.* 68° F., and effect of dissolved salts on the same; formation of protective films on heating surfaces and relation to dissolved O_2, alky., acidity, chlorides; pitting under scale; electrolytic prevention; corrosion from org. materials; action of inhibitors at boiler temps. E. M. SYMMES

Tuberculation of cast-iron pipe. CHARLES W. SHERMAN. *J. New Eng. Water Works Assoc.* **42,** 259–77(1928).—A reprint of a discussion which appeared in 1852–3. The tubercle is supposed to be a concn. of rust from the entire corroded area. Two other later examples are recorded. D. K. FRENCH

Engineering methods economically combat stream pollution (treatment of acid waste from brass cleaning). W. L. SULLIVAN. *Chem. Met. Eng.* **35,** 483–5(1928).—*Acid waste* from brass cleaning contg. HNO_3 and H_2SO_4 equiv. to 0.3% H_2SO_4 by vol. may be treated by allowing it to react with Fe shavings but is objectionable in color.

Treatment with limestone as adopted gives a clear colorless effluent which is not acid to methyl orange. 50,000–80,000 gal. per day flows through 3 wooden tanks of 0.75–1.0 in. dolomitic limestone and a fourth containing 0.25–0.5 in. high-grade limestone. Flow is downward through the first 2 tanks to permit skimming of Ca soap and upward through the last 2. Diln. to 0.3% H_2SO_4 is provided. To prevent coating the limestone, soapy water is diverted to a sanitary sewer. Crystn. of $CaSO_4$ is prevented by draining each night, use of dolomitic limestone and diln. Water is run for 2 hrs. after plant operation ceases. The stone is then flushed and sludge run to sedimentation basins. FOSTER DEE SNELL

Efficiency of a tannery-waste-treatment works. T. C. SCHAETZLE AND A. W. BLOHM. *Bull. Md. State Dept. Health* **1**, 73–84(1928); *U. S. Pub. Health Eng. Abs.* **E-637b**, 55(1928).—Wastes are screened through a Dorrco screen with 1–8 in. slotted plate and then pass through a Dorr thickener. From here they pass through a dry run to a tidal basin. Part of the sludge is dried on a bed and the remainder lagooned. The tank has a detention period varying from 0.59 to 2.16 days. Av. results of analysis show a reduction of suspended solids of 44% and O consumed 26%. The effluent has a high color, is turbid, and is still high in B. O. D. Tables showing results of analyses are included. Expts. were conducted to det. the effect of coagulants—lime, alum and iron were the most promising. Darco and Norit filters gave some promise. No data as to amt. of coagulants are included. Conclusions state that the screen and clarifier are functioning as well as could be expected, but the effluent was still highly colored, very turbid, contained much suspended matter, and had high O-consumed and B. O. D. values. C. R. FELLERS

Identification of oil-field waters by chemical analysis. C. E. REISTLE, JR. *Chem. News* **137**, 101–2(1928); cf. *C. A.* **21**, 2518.—Chem. analysis, when performed for that purpose, may assist greatly in identifying H_2O from different strata in oil fields. G. CALINGAERT

Condenser leakage. Its detection and effect on boiler-water concentration. W. C. CARMICHAEL. *Power* **68**, 267–70(1928).—Directions are given for detn. of alkali and chloride. D. B. DILL

Application of hydrogen-ion control to water and sewage work. W. A. TAYLOR. La Motte Chem. Co., Balt. *Proc. 10th Texas Water Works Short School* Jan. **1928**, 117–34; *Pub. Health Repts.* **43**, 2226–7(1928).—The application of p_H control to water purification, particularly in the matter of securing the optimum p_H for the most economical coagulation of public water supplies, is treated. With the use of alum it was found that the optimum for the majority of waters lies between p_H 5.5 and 7.0, varying with the character of water to be treated. That the proper p_H control is of great value in correction of "red water," and other problems due to corrosive action, is brought out, as well as its applicability to water-softening processes and with particular reference to boiler feed water, cooling water for condensers, and refrigerating brines. With relation to sewage-disposal work, the investigations conducted by Rudolfs, of New Jersey, are made the basis of applicability of p_H control to the most efficient sludge-digestion methods, whether in Imhoff, septic, or sep. sludge-digestion tanks. Rudolfs finds the optimum for sludge digestion is p_H 7.3 to 7.6. At Milwaukee it has been found that activated sludge can be freed from water most effectively when the p_H value is brought down to about 3.4 by the addn. of acid. The application of p_H control to the problem of industrial-waste treatment is discussed. In the treatment of various textile wastes, the most efficient purification takes place at p_H values from 6.0 to 9.0, particularly if $FeSO_4$ is used as coagulant, the most general value being 8.0 to 8.2 for copperas and 7.2 for alum. C. R. FELLERS

Sewage treatment in the light of European practice. GEORGE B. GASCOIGNE. *Eng. News-Record* **101**, 91–6(1928).—A discussion of European practice in sewage treatment based upon observations made during visits to 25 municipal sewage works in England and Germany. Chlorination is employed only in cases of emergency. Local farmers, as a rule, recognize the value of dried sludge as a fertilizer, and will take all that can be obtained. Practically all the works are experiencing difficulties because of oil, but no satisfactory soln. has been found for this problem. Progress in the development of the activated sludge process is substantial. The presettling of sewage prior to activation, and the digestion of the excess activated sludge with the primary sludge have made the process attractive for a variety of conditions. The best method of aeration is still to be detd. The practice of collecting and utilizing the gas produced during sludge digestion is increasing. At present the disposal of phenolic wastes is best accomplished by their inclusion and treatment with domestic sewage. Means for certain elimination of these wastes from drinking water is being

sought in the development of a suitable absorptive for use in connection with the regular purification processes. R. E. THOMPSON

Degasification of Imhoff tanks at Cleburne, Tex. CHESTER COHEN. *Eng. News-Record* **101,** 319-20(1928).—The sewage-treatment plant of Cleburne consists of a double Imhoff tank unit, dosing chamber, sprinkling filter and sedimentation tank. The Imhoff tank settling capacity is 5.4 hrs. and the sludge-digestion capacity is equiv. to approx. $^1/_2$ cu. ft. per capita. Septic sewage of high H_2S content, aggravated by the relative inadequacy of digestion capacity, leads to serious gassing and foaming and odor nuisance. A pump was designed, activated by the changing levels in the dosing chamber, to create a suction on the Imhoff tank gas vents. One-such unit maintains a vacuum of 6 in. of water and 2 units approx. 12 in. The gas drawn from the tank is of sufficient vol. to drive a $4^1/_2$-h. p. gas engine. The operation of the tanks has been improved to such an extent by the degasification that whereas the plant was previously considered to be overloaded, it has now been found possible to be operated with one of the tanks out of service. Foaming has been eliminated and odors have been reduced to a remarkable extent. The digestion of the sludge is also hastened. The final effluent has a stability of over 98%, a biochem. O demand of 15 p. p. m., and a turbidity of not more than 12 p. p. m. R. E. THOMPSON

Converting garbage into fertilizer. Municipal plant at Bilbao. D. RAMON ARRARTE. *Quim ind.* **5,** 123-5(1928).—After a study of the systems employed in European capitals the "Lightning" system of the Patent Lightning Crusher Co., Ltd. was adopted. A detailed description is given. MARY JACOBSEN

ELLMS, JOSEPH W.: **Water Purification.** 2nd ed., enlarged. New York: McGraw-Hill Book Co., Inc. 594 pp. $7. Reviewed in *Am. J. Public Health* **18,** 1201; *Eng. News-Record* **101,** 106(1928).

Clarification and purification of waste waters and other liquids. ANDREAS RAVNESTAD. Norw. 40,417, May 30, 1927. The content of suspended particles is removed by treating the liquid with org. colloids, especially from marine plants, which have been coagulated before or after being added to the liquid. Besides these colloids a suspension of solid, liquid or gaseous substances is also added before, during or after the coagulation of the colloids, the added suspension having the property of settling quickly either as a ppt. at the bottom or as a foam layer at the top of the liquid. The added substances are chosen in such a way that the elec. charge of the added particles is opposite to that of the original particles, in order to produce a reciprocal discharging of the particles. Cf. *C. A.* **21,** 1320.

Water softening. OTTO LIEBKNECHT (to The Permutit Co.) Can. 282,517, Aug. 14, 1928. A base-exhange compn. is manufd. by treating a material contg. a hydrated sesquioxide with an aq soln. of an alkali metal silicate under superatmospheric pressure.

Preventing incrustation in boilers. W. LAZARUS. Brit. 283,517, Jan. 12, 1927. The use of soot and soda as described in Brit. 271,337 (*C. A.* **22,** 1642) is modified by the use of a larger quantity of soot, charcoal or plumbago in finely divided form, and of an alkali or alk. carbonate adapted to the total hardness of the water. Alkali or alk. carbonate is subsequently added daily.

Boiler compound. AKTIESELSKAPET NORSK KJELERENSNINGSMIDDEL. Norw. 42,895, June 27, 1927. The following compn. is added to the water: 25-35 parts of caustic soda, 7-10 Na_2CO_3, 0.8-1.2 quebracho and 80-130 H_2O.

Increasing the efficiency of zeolites for treating water. WOLCOTT C. FOSTER and ARTHUR S. GARRETT. U. S. 1,683,967, Sept. 11. Raw water with a low initial alky. is treated with NaOH or Na_2CO_3 or other suitable salt which is alk. in soln. until a predetd. standard of alky. is reached and the water is then filtered through zeolite material.

Apparatus for [illegible] **water by treatment with iron scale or other deoxidizing material and filte**[illegible] CHRISTIAN HÜLSMEYER. U. S. 1,683,780, Sept. 11. The water may also be [illegible] to magnetic sepn. or elec. treatment.

Base-exchanging substances. ARTHUR ROSENHEIM. (Otto Liebknecht, inventor.) Ger. 463,719, July 19, 1928, addn. to 462,147. Base-exchanging substances are obtained by glassifying leucite, feldspar, nepheline, orthoclase, plagioclase, adularia, microcline, sodalite, noselite, hauynite, lazurite, analcite, natrolite, chabazite, harmotone, phillipsite, staurolite, desmine, apophyllite or ordinary glass with materials contg. the components required for base-exchanging power, *e. g.*, alkali carbonates, sulfates, lime, water glass, etc. Cf. *C. A.* **22**, 2803.

Glauconite. ARTHUR ROSENHEIM. (Otto Liebknecht, inventor.) Ger. 463,841, July 19, 1928. The base-exchanging properties of glauconite or materials contg. it are increased by heating it with solns. of salts, especially of the alkalies and ammonia at temp. above 70°. Pressure can be used. The salts mentioned are the carbonates, silicates, phosphates, borates, chlorides, nitrates and acetates of the alkalies and ammonia. The hydroxides also may be used.

Reclamation of the Fresno type black-alkali soil. W. P. KELLEY AND E. E. THOMAS. Calif. Agr. Expt. Sta., *Bull.* **455**, 1-37(1928).—Field expts. showed that the crop-producing power of the Fresno black-alkali soil can be greatly improved by the use of gypsum, S, $Fe_2(SO_4)_3$ or alum, provided these materials are applied in sufficient amts. Yields of alfalfa ranging from 6 to 11 tons per acre per annum have been produced on land which at the beginning of the expts. was entirely unproductive. The unproductivity of this soil is due to (1) an excess of sol. salts, especially Na_2CO_3, and (2) the abnormal chem compn. of the clay-like constituents of the soil. The reclamation of the soil must involve the removal of the excess of sol. salts and the conversion of at least a part of the clay constituents into Ca compds. The former may be leached out, but ordinary leaching fails to bring about the needed chem. changes in the latter. Gypsum, S, $Fe_2(SO_4)_3$, and alum produce beneficial effects on black-alkali soils but at different rates. These materials act on the sol. carbonate and the clay constituents simultaneously. Gypsum brings about these changes because of its sol. Ca, while the effect of S, $Fe_2(SO_4)_3$, and alum is due to their acidic nature, in consequence of which sol. carbonate is decompd. and Ca minerals of the soil, especially $CaCO_3$, are dissolved. The Ca thus brought into soln. reacts with the clay constituents. $Fe_2(SO_4)_3$ and alum react with the soil most quickly because of their high soly. and acidic nature. S. acts most slowly for the reason that this material must undergo oxidation before it can produce any important effect on the soil. Gypsum produced uniformly successful results on this soil only when applied at the rate of more than 10 tons per acre. Relatively large amts. of $Fe_2(SO_4)_3$ and alum are also required. On the other hand, excellent results have been obtained by applying not more than 1 ton of S per acre. S has proven to be much more economical than the other aterials. Large yields of alfalfa have been produced on soil that was badly affected with alkali and entirely unproductive at the outset by applying 1 ton of S per acre; when used in conjunction with stable manure, 1000 lb. of S per acre has given good results. Although the beneficial effect of S is dependent on oxidation, and the oxidation is brought about by certain species of bacteria, these expts have not shown any special advantage for artificially uninoculated S over that obtained from uninoculated S. Active forms of one or more of the species of S-oxidizing bacteria occur naturally in this soil and nothing appears to be gained by special inoculation of the S. Unless the soil is well drained there is no reasonable prospect of permanently reclaiming any alkali soil. Under the soil and climatic conditions that prevail in the Fresno section, the water table should never be less than 6 feet below the surface, and preferably deeper. C. R. FELLERS

A map of the agricultural soils of Italy. GIOACCHINO DE ANGELIS D'OSSAT. Univ. Perugia. *Ernähr. Pflanze* **24**, 332-5(1928).—Reproduction of map, scale 1:2,000,000, with discussion. LAWRENCE P. MILLER

(*C. A.* **20**, 2382, 2889; **21**, 976), and discussing the possible application of the method in agronomy. A. PAPINEAU-COUTURE

Calculation of soil respiration. H. Lundegårdh. *Biochem. Z.* **194**, 453(1928).—A misprint in L.'s formula ("Kreislauf der Kohlensäure in der Natur," *Jena*, **1924**, 146; cf. *C. A.* **18**, 2023) for detg. the production of CO_2 by soils is corrected, the formula becoming: $[(a - b) \times 1.858 \times V \times 60/t]/10Y$ g. of CO_2 per hr. per sq. m. of surface, where a is the original and b the final percentage value of the CO_2 content of the bell-jar, t is the time in min., 1.858 the wt. of 1 l. of CO_2 at 15° and 760 mm., V the vol. of the bell-jar in cc., and Y the surface in sq. cm. covered by the bell-jar. B. C. A.

The absorption of rain water during vegetation by the soil and its utilization by plants. N. Tulaikov and A. Kozhevnikov. *Soil Sci.* **25**, 213–24(1928).—Intensive utilization of the water resources of the soil by winter rye begins from the moment of its spring awakening. The expenditure of water by the winter rye began with the surface layers of the soil, and the accessible resources throughout a depth of 50 cm. were utilized during the dry period from May 13 to June 5, during which time 65% of the dry matter of the crop was produced. The lowering of the moisture content observed under spring wheat in May must be attributed to the surface evapn. of water. The period of utilization of moisture resources under spring wheat has been shifted 2 weeks when compared with the winter rye. During the 11 days of rapid growth the moisture content of the 50 cm. layer of the soil fell to the so-called "dead resources." After harvesting the winter rye and the spring wheat, the soil, to a depth of 100 cm., was dry to the point of its so-called "dead resources of moisture." The course of the moisture content of the soil under sunflower during the first part of its vegetation period was similar to that of the plot on the fallow. A lowering of the moisture content was noticed only from June 24 to 30 during the intensive development of the sunflower. A still greater expenditure of water was noticed in July when the greatest portion of the dry matter was produced. The soil under fallow lost its water during the spring in the same way as the soils under spring wheat and sunflower. It reached a limit of 18%. The rain during the summer did not increase the moisture content of the soil under fallow. E. F. Snyder

The measurement and interpretation of the water-supplying power of the soil with special reference to lawn grasses and some other plants. J. Dean Wilson. Johns Hopkins Univ. *Plant Physiology* **2**, 385–440(1927).—The main soil condition controlling the general vigor and color of both level and sloping lawns at Baltimore is the water-supplying power of the soil. Soil-point detns. (*C. A.* **14**, 3697) at a depth of 6 cm. should give very useful information in detg. and outlining the best irrigation practice for lawns in humid or semi-humid, temperate regions. Walter Thomas

The Gehring-Wehrmann method for the determination of the lime saturation degree of soils. A. Gehring. *Ernähr. Pflanze* **24**, 206–9(1928).—Cf. *C. A.* **22**, 294. Lawrence P. Miller

The acidity of soil for sugar cane. O. Arrhenius. *Arch. Suikerind.* **36**, 511–6 (1928); cf. *C. A.* **22**, 475.—To eliminate the influence of the phys. structure of the soil in making expts. on soil reaction, a new series of expts. was made with garden soil at the reactions p_H 4.5, 6, 7, 8, and 8.5. The variety used was 2878 POJ, the growing period 5 months. The results are given in a graph. Above p_H 7, the garden soil gave higher yields than the clay, probably because it is less affected by the addition of alkali. The results again show that a neutral reaction gives the highest yield and that the quality of the cane is probably more affected than the quantity. The Al question is of importance only on acid soils, with a p_H below 4.5, and therefore is of little or no interest for Java. Three hundred soil samples from Bandjaratma plantation were tested for Al with Goppelsröder's reagent, which is sensitive to 1 part per million. Not 1 of the 300 samples had Al. Only the most acid soils, and probably the most alk. soils could contain too much Al, but such soils are not suitable for cane cultures anyway. To change the reaction of the soil, various chemicals may be used, such as lime, press cake, marl, clay, S, H_2SO_4, etc. To det. the amt. of lime to be used, it is best to titrate with a mixt. of equiv. quantities of $Ca(OH)_2$ and $Ca(HCO_3)_2$. For North German and Swedish soils a relation between the buffer action and the hygroscopicity was found, but such a relation does not exist in Java soils. P. R. P.

Determination of carbon dioxide in carbonates in soil. A. Riad. *Analyst* **53**, 486–7(1928).—Suggestions are made to obviate the formation of $BaCO_3$ from the action of air when Hepburn's modification of the Van Slyke method is used. W. T. H.

The numbers of microörganisms in Carrington loam as influenced by different soil treatments. Lewis W. Erdman. *Iowa State Coll. Agr. Res. Bull.* **109**, 233–58(1928).—The highest nos. of bacteria were found in the soils in Mar. of 1926 and July and Nov. in 1925. Great fluctuations in nos. of bacteria occurred from one sampling to another.

The greatest no. of fungi was found in the soils in Nov., 1924, gradually decreasing during the winter months and reaching a min. in June, 1925. Another max. was reached in Jan., 1926. This increase was followed by a decrease in nos. which reached a low point in Apr. From then on great fluctuations occurred which cannot be explained from the data obtained. The nos. of actinomycetes varied with the no. of bacteria. An increase in bacteria was followed by an increase in nos. of actinomycetes. The relative proportion of these 2 groups of organisms was between 1 to 10 and 1 to 20. No correlation existed between the nos. of microörganisms and the NO_3 accumulation in the soils. The amt. of moisture varied in the soils at the different samplings, but this factor did not have any appreciable influence on the nos. of microörganisms. The nos. of fungi in this soil were not affected by application of manure alone, or of manure and lime. Superphosphate and rock phosphate, when added with lime and manure, caused a slight increase in the nos. of fungi present. The nos. of bacteria in this soil were increased by all of the soil treatments studied. Manure and lime increase the no. more than did the manure alone; manure, lime and rock phosphate increased the no. more than did the manure and lime; and manure, lime and superphosphate brought about the greatest increase in nos. of bacteria. The various soil treatments did not seem to affect the no. of actinomycetes in this soil. All of the soil treatments increased the crop yields. There was a direct correlation between the no. of bacteria in the different plots and crop yields. Where superphosphate or rock phosphate was used a correlation was noted between nos. of fungi and actinomycetes and crop yields.

Comparative tests of methods of making counts of soil microörganisms. Georg Kühlmorgen-Hille. Univ. Leipzig. *Centr. Bakt. Parasitenk.* 2 *Abt.* **74**, 497–519 (1928).—A detailed study of the effect of variations in culture media. J. T. M.

The decomposition of sodium cyanide. Alfred Aslander. Cornell Univ. *Bot. Gaz.* **85**, 462–3(1928).—NaCN decomposes rapidly in the soil but not in 0.1 *N* soln. having a reaction of p_H 11.75. This indicates that decompn. is brought about by microörganisms. Benjamin Harrow

Fertilization with potash salts and soil reaction. H. Kappen. Landw. Hochsch. Bonn, Poppelsdorf. *Ernähr. Pflanze* **24**, 281–92(1928).—An address. L. P. M.

Intensive fertilization on a rational basis. H. Neubauer. Landw. Vers., Dresden. *Ernähr. Pflanze* **24**, 273–81(1928).—On the basis of the results from the method of N. (cf. *C. A.* **18**, 877) for the detn. of available K and P in a soil, it is possible to det. quite accurately the amt. of these elements to be added to the soil. Pot culture expts. cannot be used for the exact detn. of available N; the amt. of N to be added must be based, therefore, on a knowledge of response to N application of the soil in question together with a consideration of the amt. of N used by the particular crop to be grown.
Lawrence P. Miller

The success of the use of nitrogen fertilizers in prairies and postures in Holland. Charles E. H. Boissevain. *Chimie et industrie* Special No., 121–7(April, 1928).—An address describing the increased yields and improved compn. of grass, resulting in higher milk yields, obtained in Holland by the use of N fertilizers. A. P.-C.

The toxicity to cotton seedlings of high concentrations of soluble nitrogenous fertilizers. L. G. Willis and E. A. Davis. N. Car. Agr. Expt. Sta., *Tech. Bull.* **30**, 1–12(1928).—Field expts. indicate that heavy applications of nitrogenous fertilizers are necessary for the economic production of cotton and the N should be added early in the growth of the plants for best results. The sol. forms of N are injurious when drilled in close contact to the seed. Nitrogenous compds. not fixed by the soil, even though properly distributed, may be brought to the surface by the rise of capillary moisture and reach a degree of concn. such as seriously to injure the plants. In pot expts., the concn. of N necessary to cause injury is about the same whether this element is supplied as $NaNO_3$, $(NH_4)_2SO_4$, $Ca(NO_3)_2$ or Leunasaltpeter. Heavy applications of urea were more toxic than other forms carrying the same amt. of N. The osmotic pressure of the soil soln. increased with increased rates of application of all compds. used, being least with urea and greatest with nitrates. There was no correlation between fertilizer injury and osmotic pressure of the soil soln. Absorption of N was rapid during the first 4 days of growth, NH_3 compds. being better absorbed than nitrates. The amt. of N absorbed from each compd. was increased with increases in the rate of application. Absorption was greatest when urea was used. The greater toxicity of this substance in pot expts. may result from free NH_3 formed from the decompn. in contact with the soil, a condition which might never occur in field practice.
C. R. Fellers

The biology of stable manure conservation. Br. Niklewski. Univ. Poznan.

Centr. Bakt. Parasitenk. 2 *Abt.* **75**, 206–13(1928).—Straw depresses plant growth as measured by the development of yeast cells. N in the form of $(NH_4)_2SO_4$ can overcome the inhibiting effect. Manure inoculated with nitrite bacteria loses less N than do uninoculated controls, the content of NH_3 and amino N being higher. Inoculated manure has a smaller quantity of colloidal material. JOHN T. MYERS

Comparative biological and chemical studies on different kinds of stable manure. IV. Varieties of horse manure. G. RUSCHMANN. Inst. Garungsgewebe, Berlin. *Centr. Bakt. Parasitenk.* 2 *Abt.* **75**, 182–205(1928); cf. *C. A.* **22**, 1646.—Five samples of horse manure varying in age from 1 week to 6 months were studied as to nitrite and nitrate content, and activity in nitrification and denitrification. If there has been much oxidation of NH_3 in manure its denitrifying power is weak; hence nitrites and nitrates accumulate. Those manures which denitrify actively are weak in nitrifying power. Fermentation of manure at high temps. is more important than at low temps. In thick masses, O is soon used up and nitrification stops. The balance between nitrification and denitrification is very delicate. JOHN T. MYERS

Application of activated charcoal as fertilizer for grains. S. HOLYNSKI. Inst. Agr. Pulawy, Poland. *Przemysl Chem.* **12**, 190–6(1928).—Activated charcoal furnished by the Military Gas Inst. (Warsaw) increases the crop and its content of P and N. It deserves detailed field investigation as a possible aid in fertilizing, especially in sandy soils and sands This charcoal probably regulates the consumption of fertilizers by plants. When applied in large quantities it may alter the phys. properties of the soils, *e. g.*, by changing their water capacity. When added to lime-nitrate it causes changes in that fertilizer which may mitigate the disastrous results of formation of dicyanodiamide. Its addn. to superphosphate does not increase even though it does not prevent the retrogradation of phosphoric acid. A. C. Z.

Fumigation of vineries with calcium cyanide. J. C. WOODFIN. New Zealand Dept. Agr. *New Zealand J. Agr.* **36**, 192–3(1928).—$Ca(CN)_2$ was extremely efficient as a destructor of vermin and insect pests. To avoid leaf burning, from $^1/_3$ to $^3/_4$ oz. $Ca(CN)_2$ used per 100 cu. ft. was found effective. After picking the grapes, 4 oz. per 100 cu. ft. should be used to control mealy bugs. C. R. FELLERS

Preliminary tests of ozone as an insecticide. E. N. CORY AND H. B. MCDONNELL. Univ. Maryland. *J. Econ. Entomol.* **21**, 510(1928).—At 4 mg. per l. in air, and 25 sec. to 5 min. exposure, ozone was lethal to 4 species of insects. Its action upon the larvae of 2 species could not be correctly interpreted. The adaptability of ozone to the control of stored product insects will be investigated. C. H. RICHARDSON

Notes on oil emulsions with special reference to Aphis on apple. S. W. FROST. *J. Econ. Entomol.* **21**, 504–6(1928).—Lab. and field tests with petroleum oils (kerosene and six other heavier oils of paraffin and asphaltum base) emulsified in the cold with Ca caseinate showed that a high % of rosy aphis (*Anuraphis roseus*) may be killed when a drenching spray is used. Light applications of the same emulsions gave poorer results. The oil concns. used were generally 3% by vol. In the lab. light applications gave only partial control of red spider. Apple trees, 2–12 years old, were not injured by 1.5 and 3% sprays of kerosene and red engine oil even when applied as late as June. C. H. RICHARDSON

Petroleum oil as a carrier for nicotine. E. R. DE ONG. Calif. Agr. Expt. Sta. *J. Econ. Entomol.* **21**, 502–4(1928); cf. *C. A.* **22**, 3482.—The value of petroleum oil as a spray is not confined alone to its insecticidal properties; it is potentially useful as a carrier for more active insect poisons or for fungicides. Kerosene and 3 highly refined petroleum oils (viscosity, Saybolt, 55–60, 70–80 and 106 secs., resp.) were tested as insecticides with and without the addn. of nicotine (0.01 and 0.02%) for the brown apricot scale (*Lecanium corni*). The oil-nicotine mixts. were more effective than the oils alone. It was also found that kerosene-nicotine was nearly as efficient as the heavier oils mixed with nicotine with advantages to the former in favor of cost and danger to plant tissue. Oil-nicotine mixts. are promising for use on trees in foliage. They probably will not offer advantages over other oil prepns. for dormant spraying. C. H. RICHARDSON

Naphthalene control of red spider and other insects on miscellaneous crops in the U. S. Department of Agriculture greenhouses. G. M. DARROW. *J. Econ. Entomol.* **21**, 511(1928); cf. Hartzell, *C. A.* **21**, 792.—The vaporization of 1.5–3 and 4.5 oz. naphthalene per 1000 cu. ft. of greenhouse space killed eggs and adults of the red spider, adult white flies, ants and aphids without injuring strawberries, cotton plants, cucumbers, chestnut, carnation, primrose, croton, lilies and other plants. Only a few varieties were injured by the 4.5-oz. dosage. The compd. is vaporized by a lamp. C. H. RICHARDSON

Spray recommendations for codling moth control, Washington, for 1928. E. C. JOHNSON, *et al.* Wash. State Agr. Expt. Sta., Wash. State Dept. Agr. and Federal Bureau Entomology. *J. Econ. Entomol.* **21,** 512-4(1928).—The following recommendations are made concerning the use of insecticides: $PbHAsO_4$, 1 lb. in 50 gal. water, is the only efficient insecticide to use. A mixt. of petroleum oil and $PbHAsO_4$ is effective but may injure fruit and foliage. Petroleum oil alone is not as effective as the oil and arsenical mixed. Nicotine sulfate and other insecticides are either ineffective or in the exptl. stage. Sprays should be applied to control the first brood. The no. of subsequent sprays will vary with locality and must be detd. by the grower. Thoroughness of spraying is stressed and supplementary treatments (traps, bands, orchard sanitation) are discussed. Other biol. information is given. C. H. R.

The use of arsenicals in French vineyards. L. O. HOWARD. Bureau of Entomology. *J. Econ. Entomol.* **21,** 510(1928).—The employment of arsenicals is now permitted in vineyards between date of vintage and the time when grapes begin to darken the next season. C. H. RICHARDSON

The control of the beemoth. F. B. PADDOCK. Iowa State Coll. *J. Econ. Entomol.* **21,** 489-94(1928).—SO_2, CS_2, CCl_4, HCN, *p*-dichlorobenzene, HCHO, $Ca(CN)_2$, a mixt. of CCl_4 and Et acetate and several proprietary substances are discussed as fumigants for the beemoth (*Galleria mellonella*). Conclusion: Very little is known about control measures for this insect and extensive investigations are needed. Hive sanitation, parasitic control and repellants have thus far not been successful. High and low temps. are possible control measures. C. H. RICHARDSON

Experiences and observations in the campaign against hedge mustard. J. WEIGERT AND F. FURST. Landesanstalt f. Pflanzenbau, Munchen *Ernahr. Pflanze* **24,** 110-4, 139(1928).—Broadcasting of finely ground kainite, cyanamide and mixts. of the two and spraying with solns. of Fe vitriol, "Raphanit," and kainite were tested over several years for their effect against hedge mustard. Weather conditions at the time of application greatly influenced the results. On the whole, finely ground kainite and "Raphanit" solns. gave the best results LAWRENCE P. MILLER

The relation of flies and fly sprays to milk production. S. B. FREEBORN, W. M. REGAN AND A. H. FOLGER. Calif. Agr. Expt. Sta. *J. Econ. Entomol.* **21,** 494-501 (1928).—In an attempt to ascertain the loss in milk production in cows which have been sprayed with fly sprays it was found that (1) exposing cows to a very heavy infestation of house flies (*Musca domestica*) did not lower milk production; (2) that in the absence of flies, sponging the cows with water had no effect on milk production; (3) spraying the cows with water caused a 5.4% loss in production; (4) spraying with pine tar-creosote mixt. caused a 6.9% loss; (5) spraying with a white petroleum oil (viscosity 68 Saybolt) caused a 9.7% loss. During the last 2 weeks of spraying a 12.5% loss attended the use of the pine tar-creosote mixt. and a 22.8% loss resulted from the use of the white petroleum oil. The body temp. of the oil-sprayed cows was consistently higher and the respiration rate 40% av. higher than normal (cf. *C. A.* **20,** 2555). C. H. RICHARDSON

Phosphates. F. G. LILJENROTH. Brit. 283,187, Jan. 8, 1927. Raw Ca phosphate material is treated with acid to recover H_3PO_4 and Ca is sepd. by pptn. as $CaSO_4$ which is treated with NH_3 and CO_2 to form $(NH_4)_2SO_4$ and $CaCO_3$. The $(NH_4)_2SO_4$ soln. may be used to ppt. addnl. $CaSO_4$ and finally may be neutralized with NH_3 and concd. to obtain a *fertilizer*.

Fertilizers. F. G. LILJENROTH. Brit. 283,908, Jan. 20, 1927. In treating crude Ca phosphate with acid and sol. sulfate as described in Brit. 282,330 (*C. A.* **22,** 3727 less leaching acid is used than corresponds with the lime in the phosphate.

Fertilizers and magnesium salts. F. G. LILJENROTH. Brit. 283,558, Jan. 15, 1927. Material contg. a sol. Mg salt such as $MgSO_4$ or $MgCl_2$ is dissolved in water and treated with NH_3 and CO_2 to ppt. the Mg as carbonate and form an NH_4 salt in soln. Excess CO_2 and a greater excess of NH_3 are added and are recovered from the ppt. by heating or washing with hot water and from the soln. by heating. HNO_3 is added to the ppt. and further CO_2 thereby recovered. The treatment is suitable for application to

materials such as kieserite, kainite or potash contg. Mg as an impurity. Products may be obtained which are suitable for use as fertilizers. The initial material contg. Mg may be freed from HCl by heating it with H_2SO_4. Raw Ca phosphate may be leached with HNO_3 mixed with $(NH_4)_2SO_4$ soln. obtained in the process, $CaSO_4$ formed filtered off, and the remaining soln. evapd., after neutralizing with NH_3, to form a fertilizer.

Fertilizer containing calcium nitrate and potassium nitrate. NORSK HYDRO-ELEKTRISK KVAELSTOFAKTIESELSKAB. Norw. 44,668, Dec. 5, 1927. By mixing $Ca(NO_3)_2$ (Norway saltpeter) with 5–25% of KNO_3 a mixt. is obtained which has a higher m. p. and which solidifies more rapidly after being melted than is the case with unmixed lime saltpeter.

Fertilizer containing potash and nitrogen. NORSK HYDRO-ELEKTRISK KVAELSTOFAKTIESELSKAB. Norw. 45,058, April 16, 1928. A supplement to Norw. 28,373. NH_4NO_3 is dried and granulated under addn. of less hygroscopic salts, for instance KCl. The K salt is eventually applied in amts. sufficient for making the resulting product a mixed fertilizer in which the K_2O content has a full com. value.

Treating ammonium nitrate. NORSK HYDRO-ELEKTRISK KVAELSTOFAKTIESELSKAB. Norw. 44,288, Aug. 8, 1927. The invention intends to produce an NH_4NO_3 fertilizer which can be stored in granular condition without clogging to hard lumps. NH_4NO_3 and $Ca(NO_3)_2$ are melted together to a homogeneous mass, which is then granulated. Or the salts may be mixed in soln., the soln. evapd. and the residue crushed. NH_4NO_3 also may be treated with a mixt. of $Ca(NO_3)_2$ and a sulfate, preferably $(NH_4)_2SO_4$. A suitable proportion is 10% of $Ca(NO_3)_2$ or thereabouts.

Treating ammonium nitrate and similar substances for fertilizers. NORSK HYDRO-ELEKTRISK KVAELSTOFAKTIESELSKAB. Norw. 44,691, Dec. 27, 1927. The intention of the treatment is to produce good keeping and easily spreadable fertilizers from NH_4NO_3, etc. The salt in question is treated with H_3PO_4 and afterwards with NH_3 in order to form a surface coating of NH_4 phosphate on the salt particles. Eventually so much of H_3PO_4 and NH_3 may be applied that the resulting product becomes a mixed fertilizer in which the content of P_2O_5 has a full com. value. The process is carried out under const. stirring, in one single or in 2 sep. app. Eventually the treatment may be carried out in several steps in order to avoid any considerable liberation of the original acid. In the case of NH_4NO_3 a fog of NH_4NO_3 is formed during the neutralization. This fog is removed from the app. by passing the NH_3 gas through the app. in const. circulation during which the salt fog is removed outside the neutralizing app.

Granular non-dusting calcium nitrate. NORSK HYDRO-ELEKTRISK KVAELSTOFAKTIESELSKAP. Norw. 44,149, June 27, 1927. Crushed dust-contg. $Ca(NO_3)_2$ is heated, eventually under addn. of some moisture, under const. motion in a rotary drum. The heating may be wholly replaced by the application of moisture. The crushed salt may first be passed through a classifier where the particles below a certain limit of size are sepd. and subjected to the above treatment.

16—THE FERMENTATION INDUSTRIES

C. N. FREY

Report on the sixth season's work at the experimental oast. A. H. BURGESS. *J. Inst. Brewing* **34**, 248–64(1928).—A summary is given of results of sixty kiln loads of hops dried under varying conditions. Hops dried at 8 diff. temps. between room temp. and 100° showed the same resin content. A decrease in a resin occurred in the hops dried at above 80°. Tests with sulfuring showed that SO_2 gave a slightly better colored hop than when S was burned. About 3% of the S used was retained by the hops and appeared to increase the value found for a resin, probably because of the formation of $PbSO_4$ in the method used for detg. a resin (in which the resin is pptd. as Pb salt). Measurement of the dew point of the air above the drying hops indicated that the drying power of the air was far from completely utilized, and that the present system of drying is inefficient and not economical. PETER J. F. WEBER

Simultaneous oxidation and reduction and molecular transpositions. Transposition of α-keto alcohols and the mechanism of alcoholic fermentation. AL. FAVORSKII. *Bull. soc. chim.* **43**, 551–63(1928).—This article is a general extension of F.'s work and theory on the transposition of α-keto alcs. On the basis of the theory of the intermediate formation of oxide-alcs. in the simultaneous oxidation and reduction and mol. transpositions (cf. *C. A.* **20**, 1593), F. discusses in more detail the mechanism of alcoholic fermentation. The reduction of nitro compds. to primary amines, hyposulfites to sul-

fites and hydrosulfides, and Et_2S_2 to EtSH are explained also according to analogous mechanisms. FREDERICK C. HAHN

The diastase content of grains and its practical utilization in the distillery. STAIGER. *Chem.-Ztg.* **52**, 679–80(1928); cf. *C. A.* **21**, 3913.—Maercker notes that in Russia sprouted rye is mashed without the addn. of malt. The diastase present in unmalted rye and wheat in normal unsprouted or ungerminated grains is sufficient without the addn. of malt to saccharify the starch present. High temp. drying may destroy some of the enzymes. The resulting alc. from grains malted in this manner is mild in flavor and contains only small quantities of fusel oil. This new method conserves coal and lessens labor. C. N. FREY

Dextrins contained in sweet and fermented mash. J. TROJAN. *Przemysl Chem.* **12**, 145–60(1928). A. C. Z.

Sugar: alcohol ratio and the stability of sweet wines. P. MALVEZIN. *Bull. assoc. chim. sucr. dist.* **45**, 396–9(1928).—In connection with his work on the prepn. of vaccines for the prevention of secondary fermentation, M. noted that he was always successful when the sugar/alc. ratio was less than 3, but never when the ratio exceeded 4. On reference to the data for over 100 samples of sweet wines received in his lab. on account of secondary fermentation, all were found to give a ratio of over 4 and generally nearer 6. Samples which had been recorded as keeping well had mean sugar/alc. ratios of: Gironde 1.3, Sauterne 3.65, Anjou 3.81, Gaillac 7.31. Conclusion: For sweet wines generally, the ratio should not exceed 3.5, but may reach 3.8 in Anjou wines, and 7 in Gaillac and similar wines in which secondary fermentation is usual. B. C. A.

The use of citric acid in the treatment of wine. JEANPRETRE. Neuchâtel Chem. Laby. *Mitt. Lebensm. Hyg.* **19**, 252–4(1928).—The addn. of citric acid to wines lacking in natural acidity or affected with white casse disease is advocated in Switzerland. At present it is illegal, though France, Italy, Spain and Greece have legalized the addn. of 50 g. per hectol. as a max. J. points out the difficulties of properly evaluating such wines on a basis of chem. tests. C. R. FELLERS

Uniform behavior of bottom-fermentation beer yeast in respect of fermentation, reproduction, and acid formation, on storage under water at various temperatures. F. STOCKHAUSEN AND F. WINDISCH. *Wochschr. Brau.* **44**, 557–64, 573–9(1927); cf. *C. A.* **22**, 2026, 2807.—Similar expts. to the earlier ones (*C. A.* **22**, 2026) were made with 3 other typical bottom yeasts, and with the same results. B. C. A.

The surface of yeast as a factor in fermentation. II. CLERK RANKEN AND JAMES R. BELL. *J. Inst. Brewing* **34**, 265–74(1928); cf. *C. A.* **22**, 300.—Peptone-tannin and CaC_2O_4, 2 constituents of brewery worts, were deposited on yeast, and the effect of such deposition was studied. Coating of the surface of yeast with peptone-tannin retarded the rate of fermentation, especially during the early stages, and also diminished the amount of reproduction. When traces of iron were present there was an accelerated fermentation. CaC_2O_4 coatings slightly retarded the reproduction, but when a higher rate of seeding was used, or with an increase in the coating an accelerated fermentation resulted. The retarded reproduction may possibly be attributed to toxicity of the CaC_2O_4, whereas the acceleration due to increase in coating or seeding is probably induced by the CaC_2O_4 preventing coherence of the yeast, which permits it to present a greater surface to the fermenting liquid. The peptone-tannin coatings on the other hand increased coherence of the yeast cells, and thus caused a retarded fermentation, because the increased coherence gave high heads which raised the yeast out of the liquid with consequently less yeast surface in contact with the fermenting liquid. P. J. F. W.

Fumigation of vineries with $Ca(CN)_2$ (WOODFIN) 15. Action of various kinds of EtOH on sheet Al and Lantal (RÖHRIG) 9. Paper pulp [alcohol produced in manufacture of] (Brit. pat. 283,851) 23.

WEICHHERZ, J.: **Die Malzextrakte.** Berlin: J. Springer. 388 pp. R. M., 32.

Distilling alcohol. U. S. INDUSTRIAL ALCOHOL CO. Brit. 283,701, Nov. 29, 1926. Alc., distd. from dil. alc. liquids as described in Brit. 278,211 (*C. A.* **22**, 2636) is, without cooling, dehydrated by distn. in the presence of a liquid such as C_6H_6 which forms an azeotropic mixt. An app. is described.

Beer. HOFBRAUHAUS WOLTERS UND BALHORN A.-G. Brit. 283,879, Jan. 18, 1927. Special beers having the properties of beers brewed in Pilsen are made by using the condensate of steam from brewing operations (with its contained heat if desired) for mashing and sparging. The condensate from the mash tuns and boiling coppers may be mixed with deep well water until it is brought to a hardness of 2°.

Yeast. AKTIESELSKABET DANSK GAERINGS INDUSTRIE. Brit. 283,969, Jan. 21, 1927. In using molasses for yeast and alc. production, acidifying and nutrient substances are used which do not contain SO_4 ions so that spent washes are obtained which are free from noxious products. The p_H of the wort is obtained by adding HCl, and NH_4 chloride, carbonate or phosphate may be used as nutrients. Brit. 283,970 specifies treating molasses, preparatory to its use for yeast and alc. production, with betaine-decompg. bacteria propagated on betaine or betaine-HCl (which process can be combined with the usual production of lactic acid by bacteria). The material may be then treated with an alkaloid-pptg. reagent such as tannic acid, may be decolorized by $Al_2(SO_4)_3$ and NaOH and the sulfates and carbonates present may be pptd. with a Ba compd. Silicates of Na and K may be used for removing excess Ba or Al ions. Ba aluminate also may be used in the purification and the treatment may be modified in accord with the character of the molasses to be treated.

17—PHARMACEUTICAL CHEMISTRY

W. O. EMERY

The investigation of essential oils. FREDERICK CHALLENGER. *Ind. Chemist* **4**, 315–9(1928).—The history of the work that revealed the nature of the essential oils, especially that of Wallach, is briefly covered. The methods for the isolation of the ketones, pulegone and thujone are described, as well as their chemistry and physiol. properties. The occurrence and chemistry of carvone and some of its derivs., of piperitone, and of 2 new terpenes (Δ^3-carene) and (Δ^4-carene), are discussed. Sylvestrene is thought not to occur in nature, but is probably evidence of the presence of a carene hydrocarbon, the trimethylene ring of which undergoes fission. The results are given of the work of Wallach, Ruzicka, and Semmler on the sesquiterpenes, followed by a short account of the work done on squalene. Bibliography. E. G. R. ARDAGH

Occurrence of arsenic in tobacco. H. POPP. *Z. angew. Chem.* **41**, 838–9(1928).—For the detn. of As in tobacco 200 g. is heated with fuming HNO_3 until the org. matter is completely decompd. and all Cl expelled. The soln. is evapd. repeatedly with H_2SO_4 to remove HNO_3, and As is tested for by the $HgCl_2$ colorimetric method. Tobacco from the Palatinate contained 5.1, from Macedonia 0.7, from Java 0.33, and from Brazil 4.6 pts. of As per million. This quantity is so small that no danger of poisoning is to be feared. B. C. A.

Improved technic of the thalleoquine reaction for quinine. H. W. VAN URK. *Pharm. Weekblad* **65**, 847–9(1928).—The sensitivity of this reaction, whereby a green color is developed by oxidation, is much greater if eau de Javelle (KOCl) is used in place of $Cl\text{-}H_2O$ or $Br\text{-}H_2O$. Quinine in a concn. of 1 to 40,000 is thus readily detected. Eau de Javelle has the additional advantage of being a more stable reagent. A. W. DOX

Liquor aluminii-tartarici D. A. B. 6. HERMANN MATTHES AND PAUL SCHÜTZ. Univ. Königsberg. *Apoth. Ztg.* **43**, 1023–4(1928).—The official German prepn. contains in addn. to Al acetotartrate considerable basic Al acetate. The pharmacopeial method of evaluation does not give the true content of Al acetotartrate. A positive result following the Zn acetate test of the official prepn is conditioned, as in the case of alsol, on a low content of tartaric acid. The ppt. arising in the Zn acetate test, and consisting chiefly of Al acetotartrate, is caused by the added EtOH, for which reason the satd. alc. Zn acetate test soln. can be omitted. W. O. E.

Estimation of cresol in liquor cresoli saponatus. K. FEIST. Univ. Göttingen. *Apoth. Ztg.* **43**, 1024–5(1928).—An improvement in the official German method consists in treating $^1/_{20}$ of the united petr. ether exts. in a tared 100-cc. beaker provided with glass rod with 5 cc. CH_2O soln. and 4 cc. 25% HCl on the water bath, the mixt. being stirred from time to time, then the residue comminuted by means of the rod, and finally brought to const. wt. in a desiccator. The residue amounted in most cases to 1.03 g. From 1 to 1.1 g. may be taken as the limits. W. O. E.

Artificial bath preparations. W. PEYER AND H. IMHOF. *Apoth. Ztg.* **43**, 1030–3, 1051–3, 1074–5(1928); cf. *C. A.* **22**, 302.—A descriptive treatment including analytical results in the examn. of certain com. prepns. W. O. E.

Testing aluminum acetate of the German Pharmacopeia. OTTO SCHMATOLLA. *Pharm. Zentralh.* **69**, 568–9(1928).—A critical commentary on the official German method, with certain suggestions for improvement. W. O. E.

Commercial cholesterol. I. LIFSCHÜTZ. *Chem.-Ztg.* **52**, 609–10(1928).—This

material, largely obtained in the manuf. of lecithin from cattle brain or from egg oil, is rarely pure, but quite generally contaminated with metasterol. W. O. E.

Superfluous pharmaceutical preparations. ANON. *Chem.-Ztg.* **52**, 611(1928).—A specific instance is cited with nautisan (trichloroisobutyl alc. and trimethylxanthine), which is nothing more than a mixt. of chloretone (introduced years ago by Parke, Davis & Co.) and caffeine. W. O. E.

Color reactions of atropine and certain of its related compounds. LAD. EKKERT. Budapest. *Pharm. Zentralh* **69**, 529–31(1928).—A study has been made of the various color changes produced on the addn. to 0.005–0.01 g. of the alkaloid (atropine, hyoscyamine, homatropine, novatropine) and powdered phenol (resorcinol, orcinol, pyrogallol, etc.), of 0.5–1.0 cc. concd. H_2SO_4. W. O. E.

Avoidance of errors in the evaluation of essential oils in drugs. R. BAUER. *Pharm. Ztg.* **73**, 920–1(1928).—Certain sources of error are discussed in connection with the extn. of essential oils from drugs, using pentane and brine as immiscible solvents. Reference is particularly directed to the technic of avoiding contamination of the org. solvent with traces of brine. W. O. E.

Evaluation of essential oils in drugs. HANS KAISER AND KARL EGGENSPERGER. *Pharm. Ztg* **73**, 1036(1928).—Reference is made to the paper by R. Bauer on the avoidance of errors in the above evaluation (cf. preceding abstract), with certain suggestions for improvement in the technic, notably in the recovery of oil possibly held in emulsified brine. An illustration of the app. used by the author is shown. W. O. E.

Concentrated phosphorus oil. P. BOHRISCH. *Pharm. Ztg.* **73**, 954–8(1928).—A discussion of P oils in general, and of exptl. results in particular, to det. the causes of deterioration in the official Ger. stock soln. The results show that the stability of a concd. P oil as prescribed in the Ger. Pharm. depends largely if not wholly on the quality of liquid paraffin employed. W. O. E.

One hundred and fifty years of pharmaceutical chemistry at the University of Königsberg. HERMANN MATTHES. *Pharm. Ztg.* **73**, 1041–52(1928).—This univ. began to function in 1544 with 11 professors and 200 students. Its pharm. faculty has included the following teachers and scientists: Karl Gottfried Hagen, Friedrich Dulk, August Friedrich Gustav Werther, Carl Graebe, Hermann Spirgatis, Heinrich Klinger and Alfred Partheil. Their activities are described in greater or less detail. W. O. E.

A reaction for the determination of the strength of spirits of gentian. TH. VON FELLENBERG. Swiss Bd. of Health Lab. *Mitt. Lebensm. Hyg.* **19**, 242–51(1928).—A roughly quant. colorimetric method is described as follows: To 5 cc. of the suspected spirits of gentian in a test tube add 5 cc. of low-boiling petroleum ether and shake vigorously. Transfer the mixt. to a small sepg. funnel and sep. Mix the ether-layer with 1 cc. H_2SO_4 (1:1), shake well and place in the water bath. As soon as the greenish blue color develops, remove from the water bath, cool and compare the color with known standards made up from $Co(NO_3)_2$ and $K_2Cr_2O_7$. A *microcolorimeter* is used to make the comparisons. The color intensities are given numerical values which may be used in evaluating samples of spirits of gentian. C. R. FELLERS

Absorption spectra. R. G. LOVARTE AND MARGARITA H. DE BOSE. *Univ. Nac. La Plata, Estudio Ciencias*, No. **82**, 197–208(1928); *Science Abstracts* **31A**, 372.—Absorption spectra of yerba maté and of its principal adulterants, caona, caneton and auta are compared. Standardizing an alc. soln. of yerba maté is discussed. H. G.

Alterations of pharmaceutical preparations in pharmacies. C. INVERNI. *Boll. chim. farm.* **67**, 427–34(1928).—The changes are caused by H_2O, O_2, CO_2, light and heat, hydrolysis, oxidation, change of p_H, catalytic decompn., crystn. M. J.

A few derivatives of anesthesine-urea. ST. WEIL AND J. ROZENTHAL. *Roczniki Chem.* **8**, 44–9(1928).—*Ethyl p-ureidobenzoate* (I) was obtained by heating p-$C_6H_4(NH_2)$-CO_2Et with urea several hrs. to 132°, until the liberation of NH_3 has ceased, m. 213° from 95% alc. It was refluxed 24 hrs. with AcCl in glacial AcOH and neutralized with $NaHCO_3$. After 0.5 hr. the sym. *acetyl deriv.*, $EtO_2CC_6H_4NHCONHAc$, settled out, m. 139–40° from ligroin. It is sparingly sol. in water, more sol. in alc., $CHCl_3$, acetone and benzene, very easily in ether. On refluxing with excess $(CH_3)_2$-C_2H_3COCl in $CHCl_3$ until the HCl liberation ceases, neutralization of the heavy oil with $NaHCO_3$ and recrystn. of the amorphous mass from water the sym. *ethyl p-isovalerylureidobenzoate*, m. 237°, is obtained. Sym. *p-α-bromoisovalerylureido deriv.*, m. 134–5° from dil. alc., was prepd. by heating I with $Me_2C_2H_3BrCOBr$ to 100° until no more HBr was evolved. Its *hypnotic* effect is not greater than that of *bromural* but it has a greater *sedative* effect. In the rabbit 0.3 g./kg. causes somnolence and sleep

after 1 hr.; 0.2 g./kg. causes a dog to lose its equil. but the excitation is less pronounced than with bromural. MARY JACOBSEN

Investigations of a few ipecacuanha preparations. E. HOST MADSEN. *Dansk. Tids. Farm.* **2,** 145–51(1928).—Two concd. prepns. (1:20) of ipecacuanha roots were examd. One of these prepns. was prepd. by percolation, the other by twice repeated infusion with H_2O. In both cases an addn. of HCl was used. The latter method is probably preferred, because it demands shorter time than the first one. Both prepns. contained nearly the total amt. of alkaloids present in the root, and could easily be standardized to a content of 0.10% alkaloids. With a content of 18% alc. they are stable and are well adapted for prepg. infusions and sirups of ordinary strength. O. A. NELSON

Tablets and limits of errors for tablets. T. P. ELKJER. St. Jakobs Apotek, Köbenhavn. *Dansk Tids Farm.* **2,** 151–76(1928).—E. discusses the uses and compns. of medicinal tablets, particularly with regard to errors that are allowed by the pharmacopeia of diff. countries, and also the compn. of tablets manufd. in countries where no definite laws or rulings to this effect exist. He repeats statements made in 1922 to the effect that tablets should contain active principles in uncombined or unchanged condition, that certain inactive portions, binders, etc., should be allowed, and that tablets should break up or dissolve in H_2O within a certain period of time. These suggestions have evidently not been incorporated in the Dan. Pharm. To discover the source of error E. prepd. 1278 tablets, using milk sugar as the base, the fineness of which ranges from 10 to 30 mesh. Also a large no. of other tablets were prepd. by pupils in his lab. by automatic machines. The diam. of die, pressure applied, etc., are discussed Tables and curves showing the results obtained are given. Conclusions: Errors due to machines should not exceed 10%. One may demand that the error in 95% of 100 tablets should be within $\pm$7.5%, and in 85% within $\pm$5%. O. A NELSON

Essential oils of travancore. VII. From the rhizome of ginger, Zingiber officinale. KISHORI LAL MOUDGILL. Maharaja's College of Science, Trivandrum. *J. Indian Chem. Soc.* **5,** 251–9(1928).—A study is made of the essential oils obtained from ginger and ginger scrapings. Fresh ginger and samples a yr. old were steam-distd. to give 2% of an essential oil. On vacuum distn. 70% zingiberene (I), b_3 119–123°, d_{30} 0.8638 $[\alpha]_D^{30}$ −64.0, n_D^{30} 1.4870, a sesquiterpene hydrocarbon, is obtained. I gives a nitrosite, m. 92–94°, and on standing 6 months the latter's m. p. rose to 113°. I exposed to the air 3 months did not form a nitrosite and had the following consts.: $[\alpha]_D$ +2.3, n_D 1.502, d. 0.9345. Bubbling air through I produced the same change in 8 hrs. Boiling I for 45 min. gives a viscous dextrorotatory product differing from that obtained by exposure to air and from isozingiberene. The properties of the product obtained by the heating are: fraction boiling below 265°, n_D^{30} 1.492, d_4^{27} 0.8777, $[\alpha]_D^{30}$ +6.9; fraction boiling 265–70°, n_D^{30} 1.491, d_4^{27} 0.8835, $[\alpha]_D^{30}$ +7.8. The oils obtained from green ginger and ginger scrapings have the following resp. consts., d_4^{27} 0.8800, 0.8816; $[\alpha]_D^{30}$ −26.4°, −9.85°; n_D^{28} 1.4878, 1.4862. D. H. POWERS

Determination of alkaloids by the mercurimetric method. AL. IONESCO-MATIU AND H. VARCOVICI. Univ. of Jassy. *Bull. soc. chim. România* **10,** 5–8(1928); *Bull. soc. chim. biol.* **10,** 932–6; cf. *C. A.* **21,** 2445, 3575; **22,** 3733.—A detn. of the 0.1 *N* NaCl equiv. (cf. *C. A.* **17,** 1769) of atropine, aconitine, papaverine, narcotine, brucine, veratrine and emetine using Mayer Valzer reagent (cf. *C. A.* **18,** 1631). P. THOMASSET

Titration of alkaloids in pharmaceutical preparations. AL. IONESCO-MATIU AND H. VARCOVICI. Univ. of Jassy. *Bull. soc. chim. România* **10,** 9–13(1928).—A comparison of the mercurimetric method (cf. *C. A.* **18,** 1631) and the French Codex method applied to pharmaceutical prepns. The mercurimetric method is just as accurate and quicker than the Codex method. P. THOMASSET

A new reaction for eserine or physostigmine. M. MOKRAGNATZ. *Bull. soc. chim. biol.* **10,** 905–8(1928).—The reagent used is prepd. by dissolving 1 g. of benzidine in 10 cc. of AcOH (strength not stated) and 30 cc. of water by aid of heat. The soln. is made up to 50 cc., is cooled and filtered, and preserved in brown glass bottles. The test is made by adding 1 or 2 drops of the reagent to the dry residue contg. the alkaloid then 1 drop of 30% H_2O_2 and observing the color formed. Twenty-one of the more common alkaloids as bases gave a yellow-orange color. Eserine as the free alkaloid or salt gave a violet color immediately or after a time according to the quantity present. The action was positive when eserine was mixed with other alkaloids. Chlorides and bromides give a blue or bluish green color and should be absent when the test

is made. If they are present with eserine the test shows a blue or bluish green color at first, which is followed by more or less violet color. L. W. RIGGS

Studies on the standardization of germicides. Preliminary report. WM. NYRI. *J. Am. Pharm. Assoc.* **17,** 449–53(1928).—An attempt to express the germicidal efficiency of PhOH, EtOH and tinct. of I in graphic form. Four organisms were tested in the absence of and in the presence of org. matter. A fifth is to be tried. Concn. and time are the chief factors. Formulas are given for efficiency of the substances with the 4 organisms. L. E. WARREN

Analysis of ginger and its preparations. J. F. CLEVENGER. *J. Am. Pharm. Assoc.* **17,** 630–4(1928); cf. *C. A.* **22,** 3956.—The U. S. Pharm. X gives no standards for ginger or its prepns. Place 50 cc. of fluid ext. of ginger or the equiv. amt. of the Et_2O ext. in a beaker and evap. on the steam bath to remove solvents. Transfer the residue to the special app. (*C. A.* **22,** 2439) and det. the volatile oil by the method therein described. Allow the volatile oil to stand until clear and det. its phys. consts. by the usual methods. Transfer the cooled H_2O from the app. to a separator and ext. it with Et_2O. Ext. the residue in the flask with Et_2O. Unite the exts. and evap. in a weighed beaker on the steam bath using a current of air. Dry the residue in a vacuum desiccator over H_2SO_4 for 2 hrs. and weigh as non-volatile Et_2O-sol. ext. This is considered the active principle. Dissolve the residue in EtOH and det. the I and sapon. values in suitable aliquot portions by the U. S. Pharm. methods. Prepns. of African, Cochin and Jamaican ginger were studied. The volatile oil in the fluid ext. ranged from 1.5 to 2.55%, α_D −46 to −52°, n_D 1.491–2, d. 0.877–85; the non-volatile Et_2O-sol. ext. ranged from 4 to 6.27%; I no. 23.1–36.5; sapon. no. 31–54.1. The values for the Et_2O ext. were practically identical in all samples. L. E. WARREN

Soap perfuming notes (ANON) **27.** New iodo derivatives of phthaleins (GREENBAUM) **10.** Soap [remedy for rheumatism] (U. S. pat. 1,684,336) **27.** Apparatus for cooling jets of air, anesthetic gases, etc. (Brit. pat. 283,583) **1.** Phthalamic acid (Can. pat. 282,407) **10.** Odor and constitution among the mustard oils. IV. Effect of F. substitution (DYSON) **11A.**

Anesthetic. AUGUSTE CHESNAIS. Can. 282,408, Aug. 14, 1928. An anesthetic results from a combination of Et phthalamate with Et *p*-aminobenzoylphthalamate-HCl.

Medicinal ampoules. I. G. FARBENIND. A.-G. Brit. 283,952, Jan. 22, 1927. Open-ended tubes are hermetically sealed with wax, ceresin, a cellulose ether or other suitable material which is inert to the contents of the ampoule thus formed. The seal may be perforated and the contents released drop by drop, at the time of use.

Medicinal dye preparations. CHEMISCHE FABRIK VORM. SANDOZ. Brit. 283,565, Jan. 15, 1927. Disazo dyes prepd. from 1 mol. proportion of a tetrazo compd. of the diphenyl series and 2 mol. proportions of an aminonaphthalenedisulfonic acid, or an aminonaphtholdisulfonic acid, in which the sulfo groups are in the 3- and 6-positions of the naphthalene nucleus, are mixed with salts of bile acids, to form prepns. which are toxic to certain blood parasites and are particularly suitable for certain veterinary uses; *e. g.*, Chloramine blue 2B, Chloramine blue 3B (trypan blue) or Trypan red is mixed with Na cholate, taurocholate, glycocholate or desoxycholate.

Anti-diabetic product. GEORGE B. WALDEN (to Eli Lilly and Co., to The Governors of the Univ. of Toronto). Can. 283,631, Sept. 25, 1928. An anti-diabetic product from the pancreas is prepd. by extg. the pancreas with a soln. that takes up the anti-diabetic hormone thereof without destroying it or prevents its destruction by enzymes, such as trypsin, in the pancreas, sepg. the soln. from the pancreas residue and treating it to sep. said hormone from the major part of the contaminating substances, forming a soln., and adjusting the H-ion concn. to the vicinity of the isoelec. point of a substance which, following upon the said adjustment, forms a ppt. including the anti-diabetic hormone, and sepg. and preserving the ppt. thus formed.

Albuminoids. S. POSTERNAK and T. POSTERNAK. Brit. 283,866, Jan. 17, 1927. The P-contg. compd. "α" obtained from egg yolk by the process described in Brit. 268,806 (*C. A.* **22,** 1416) is treated with a suitable proportion of an Fe salt so that there is obtained a product contg. Fe (not combined as a salt) which is quite similar to the compd. "β" described in Brit. 268,806. Numerous examples, details and modifications are given, for obtaining *therapeutic compds.*

Hormones. I. G. FARBENIND. A.-G. Brit. 283,493, Jan. 11, 1927. The process described in Brit. 279,123 (*C. A.* **22,** 2813) for purifying exts. of the active principle of the ovary is applied to other glands of internal secretion such as male germ glands and the exterior lobe of the hypophysis. The material may be extd. with an org.

solvent, the concd. mass taken up with ether, the ether evapd. and the residue taken up in diethylin. Impurities are removed by fractional pptn. with water and the filtered liquid is finally concd.

Vaccines. CURT RÄTH and HANS DAHMEN. Can. 283,325, Sept. 18, 1928. To make vaccines cultures of cocci are treated with solns. of the Na deriv. of 2-hydroxy-5-iodopyridine.

Vitamins. FIRM OF E. MERCK. Brit. 283,557, Jan. 14, 1927. Antirachitic prepns. are made by the action of activating light rays on ergosterol or exts. contg. it, such as yeast fat.

Vitamin extracts. AAGE W. OWE. Norw. 43,892, March 28, 1927. Vitamin exts. are prepd. from vegetable materials by extg. with alc. or similar liquids with a small addn. of alkali, preferably in absence of air. For instance, 20 kg. of carrots is ground and dried *in vacuo* at 50–60°. The dried and cooled mass is pulverized. The resulting fine powder is treated for 8–10 hrs. at 50–60° in an indifferent atm. with 10 l. of alc. to which has been added 100 g. of NaOH. After cooling the soln. is filtered, the clear filtrate is neutralized with HCl and the alc. is distd. off *in vacuo*. If necessary the NaCl can be removed from the vitamin-contg. residue by washing with water.

Vitamin extracts from marine oils. AAGE W. OWE. Norw. 44,017, May 16, 1927.—The oil is saponified, the soap is decomposed by acids, the fatty acids are removed and the residue is extd. with a suitable substance, for instance a fat solvent, a fatty oil or a mixt. of both. The process is as much as possible carried out in absence of light and air. For instance, 10 kg. of fish oil is saponified with 2.5 kg. KOH dissolved in 20 l. H_2O. The heating is continued until sapon. is complete or nearly complete. The mixt. is cooled to 30° and an equivalent amt. of HCl is added with stirring, as quickly as possible. When the fatty acids have accumulated in a top layer the aq. bottom layer is extd. with 5 kg. of cotton oil by vigorous stirring for 2 hrs. in an O-free atm. After sepn. the oil will contain a large part of the vitamins contained in the original oil and will be practically free from the unpleasant taste of the original oil. Cf. *C. A.* **21**, 3992; **22**, 845.

Physiologically active extracts. WILLI LUDWIG and OTTO SCHAUMANN (to Winthrop Chemical Co., Inc.). Can. 283,621, Sept. 25, 1928. Physiol. active exts. are prepd. from the hearts of warm-blooded animals, by extg. the fresh water-contg. hearts with acetone, preferably under a neutral or weakly alk. reaction and then freeing according to one of the known methods the acetone soln. from the ballast substances. The exts. are intended to be used in the treatment of cardiac diseases.

Acridine derivatives. I. G. FARBENIND. A.-G. Brit. 283,510, Jan. 11, 1927. Nitro-9-aminoacridine derivs. which contain a further basic residue either in the 9-amino group or in the nucleus are prepd. either by condensing a nitro-9-chloroacridine with a base contg. at least 2 N atoms (one being of primary character) or by condensing a nitro-9-chloroacridine contg. a basic group with NH_3 or a primary or secondary amine. 9-Ethers may also be used instead of 9-chloroacridines. The products are strong *bactericides*. Examples are given of the production of 2-ethoxy-6-nitro-9-(β-diethylaminoethylamino)acridine, 2-ethoxy-6-nitro-9-(γ-diethylamino-β-hydroxypropylamino)acridine, 2-ethoxy-6-nitro-9-(*p*-β-diethylaminoethylaminophenylamino)acridine, 2-ethoxy-6-nitro-9-(*p*-γ-diethylamino-β-hydroxypropylaminophenylamino)acridine, 2-ethoxy-6-nitro-9-(*p*-γ-diethylaminoethylamino-β-hydroxypropylaminophenylamino)acridine, 2-ethoxy-3,6-dinitro-9-(*p*-β-diethylaminoethoxyphenylamino)acridine and 2-β-diethylaminoethoxy-6-nitro-9-aminoacridine and intermediates for the production of compds. of this character.

Emulsions for use in ointments, shaving creams, etc. T. D. KELLY. Brit. 283,711, Dec. 13, 1926. Aq. emulsions are prepd. by heating a mixt. of water 1–3, oils, fats or solidified oils 1 and a mixt. of glycerol and starch (in the proportions of 2–3:1) 0.5 part. For use as a liniment, the starch-glycerol mixt. is replaced by 0.1 part of a mixt. of equal proportions of starch and glycerol and a small proportion of NH_3 is added. Other ingredients may also be added and the compn. may be sterilized with ultra-violet light.

18—ACIDS, ALKALIES, SALTS AND SUNDRIES

E. M. SYMMES

The oxidation of ammonia. BRUNO WAESER. *Chem. App.* **15**, 169–71, 183–5 (1928).—A review of work in Germany after 1914 and in America, with calcns. of difference in cost of HNO_3 from NH_3 and Chile $NaNO_3$, and comparative costs of NO

for H_2SO_4 chambers from NH_3 and $NaNO_3$. Methods of operating in England and America are mentioned, with 5 cuts of app. J. H. MOORE

Catalytic oxidation of ammonia. VII. L. ANDRUSSOV. *Z. angew. Chem.* **41,** 205–6(1928); cf. *C. A.* **22,** 716.—A reply to criticism by Raschig of previous work (cf. *C. A.* **22,** 668). A. re-states his reasons for believing that nitroxyl, HNO, is an intermediate product of the catalytic oxidation of NH_3. **Reply.** F. RASCHIG. *Ibid* 207. **VIII.** L. ANDRUSSOV. *Ibid* 262–3.—Views on the mechanism of the reaction between NH_3 and O_2 in presence of Pt as previously published are summarized. Nitroxyl is regarded as the intermediate product. The large production of N_2 at high temps. and low velocities is not explicable as due to thermal decompn. of NH_3 or reaction between NH_3 and nitric oxide. It is produced in an explosion zone in front of the catalyst, which zone disappears with increasing gas velocity. The conditions of reaction with excess of O_2 suggest the presence of a layer of O_2 at the catalyst surface, whereby nitroxyl and nitric oxide are formed in preference to di-imide. In absence of a catalyst N_2 is the chief product of oxidation of NH_3. B. C. A.

The formation of ammonia in the electric discharge in the presence of mercury. A. J. A. VAN DER WYK. Univ. de Genève. *J. chim. phys.* **25,** 251–89(1928).—An elec. discharge of 10,000 v., at 50 cycles per sec. was passed from a Hg electrode through a mixt. of N_2 and H_2 at 45° and 100 mm. pressure. The formation of NH_3 takes place according to the reactions: $H_2 = H^+ + H + \epsilon$, $H^+ + H_2 = H_3^+$, $H_3^+ + Hg = HgH_3$, $^1/_2 N_2 = N^+ + \epsilon$, $HgH_3 + N^+ = NH_3 + Hg$. The reaction takes place on the surface of the Hg and is assumed to be heterogeneous. Larger amts. of NH_3 were obtained by increasing the surface of the Hg. The optimum speed of the reaction is attained with a mixt. of 2 vols. H_2:1 vol. N_2. The presence of traces of O_2 renders the Hg less active. E. G. VANDENBOSCHE

Preparation of alkali aluminates by action of chlorides on alumina in presence of water vapor. LOUIS HACKSPILL AND JEAN SALOMON. *Chimie et industrie* Special No., 415–6(April, 1928); cf. *C. A.* **21,** 4031.—On heating calcined Al_2O_3 and dry NaCl in a current of superheated steam the reaction $6NaCl + Al_2O_3 + 3H_2O = 2Al(ONa)_3 + 6HCl$ begins at 600° and proceeds quite rapidly. At 800°, 80% of the Al_2O_3 is transformed in 40 min. A lower yield was obtained in vacuum than at atm pressure. In the metallurgy of Al, it is necessary to use a very pure Al_2O_3, generally obtained by treating bauxite with Na_2CO_3 or NaOH. Since NaCl + $2H_2O$ in vapor form reacts like NaOH under certain conditions, 2 parts of bauxite contg. too much SiO_2 to be used for the manuf. of Al (Al_2O_3 60, SiO_2 11, Fe_2O_3 4, TiO_2 3, H_2O 22%) were mixed and heated with 5 parts NaCl. After 2 hrs. at 830° Al_2O_3 was pptd. with CO_2, giving yields of 73–82% of the amt. contained in the bauxite taken. A bauxite suitable for the manuf. of Al (Al_2O_3 61, SiO_2 2, Fe_2O_3 22, TiO_2 1, H_2O 14%) under the same conditions gave yields not exceeding 55%; and a bauxite of intermediate compn. (SiO_2 7%) gave a 67% yield. In all cases the Fe remained insol., but a considerable proportion of the SiO_2 was dissolved. The difference in the behavior of the Al_2O_3 is attributed to the fact that Al silicate reacts much more readily than hydrated Al_2O_3, which was confirmed by the fact that kaolin was almost quant. converted into $2SiO_2.Al_2O_3.2Na_2O$ in 2 hrs. at 900° and atm. pressure. A. PAPINEAU-COUTURE

Industrial treatment of phosphorites. S. I. VOLFKOVICH AND V. P. KAMZOLKIN. *J. Chem. Ind.* (Moscow) **5,** 474–80(1928).—While rock phosphates rich in P_2O_5 are usually treated by the thermic process which consists in heating them with C and SiO_2 above 1350° and distg. H_3PO_4, Russian phosphorites, which generally have a low P_2O_5 content, should be treated by the wet process which consists in decompg. the phosphates by H_2SO_4. The latter process was investigated with a view to rendering it more economic by obtaining by-products which have a market value. Phosphorite powder is repeatedly decompd. by either 15 to 20% H_2SO_4 or by a mixt. of H_2SO_4 and $(NH_4)_2SO_4$ to obtain $NH_4H_2PO_4$. After decantation or filtration the solid residue, which usually contains 45 to 70% gypsum, variable amts. of silicates and sesquioxides and about 2 to 4% P_2O_5 as phosphates, is suspended in powder form in H_2O and treated by NH_3 and CO_2: $CaSO_4 + 2NH_3 + CO_2 + H_2O = (NH_4)_2SO_4 + CaCO_3$. $(NH_4)_2SO_4$ and most of the phosphates dissolve. About 1.5 to 2% of the phosphates, which were in H_2O-insol. form, ppt. together with $CaCO_3$. The soln. contg. $(NH_4)_2SO_4$ may be concd. by evapn. to obtain the solid fertilizer, and the ppt. of $CaCO_3$ transformed into $Ca(NO_3)_2$ by action of HNO_3. All the products obtained from the phosphorite are thus transformed into fertilizers. This method of treatment is still in the lab. stage. B. N.

Manufacture of copper sulfate from brass turnings. I. B. EVTUSHENKO. *J. Chem. Ind.* (Moscow) **5,** 522–3(1928); cf. Kazarnovskii and Zvenigorodskaya, *C. A.* **22,** 3119–20.—The advantage of using brass turnings rather than Cu is the lower cost

of the former; the disadvantage is the presence of a large quantity of Zn which must be removed. The usual compn. of brass is: Cu 68.80, Zn 29.23, Fe 2.41%. The following 2 methods of using brass turnings in the manuf. of $CuSO_4$ are at present in use in Russian factories. In the first method brass turnings are roasted to obtain various oxides depending on the extent of calcination, and these oxides are put into dil. H_2SO_4, whereupon all CuO dissolves, but Zn and Fe oxides dissolve only partly. The undissolved part of the metal is again roasted. The soln. obtained gives in 1 crystn. $CuSO_4$ contaminated by Zn, which must be recrystd. This method involves a considerable expense of fuel, lengthy crystns., and an undesirable by-product in the form of mother-liquors contaminated with very much Zn. In the second method the turnings are subjected for 2 weeks to a treatment with hot H_2SO_4 without access of air. This leaves Cu undissolved, but Zn dissolves until only 0.25 to 0.5% of the latter metal remains. Then the treatment is continued with fresh H_2SO_4 while blowing in air, whereupon Cu dissolves and $CuSO_4$ is finally obtained from the soln. by crystn. E. shows that the second method, which has the inconvenience of being lengthy, can be improved by the use of catalyzers which, on being added to H_2SO_4, reduce the time required for the soln. of Cu. The following catalyzers have been tried: compds. of Al, Mn, P, Cr, HNO_3, etc. The best results were obtained with Cr, its role being that of a carrier of O_2. When H_2SO_4 contains 0.4% of its weight of Cr the speed of soln. of Cu in a current of air is increased 4 to 5 times, and the soln. obtained contains not more than 0.2% Cr, too small a quantity to influence the purity of the $CuSO_4$ crystals obtainable. The part of the operation which consists in dissolving away the Zn from the Cu can be accelerated by replacing H_2SO_4 by HCl, which acts much more energetically on the turnings. Whereas 2 weeks are required to dissolve the Zn of the brass by H_2SO_4, 8 hrs. with HCl are sufficient for lowering the Zn content from 29% to 1.7 to 2.0%. The strength of the HCl soln. to be used for this purpose is 17 to 18° Bé. (*i. e.*, 0.14 to 0.16 g. HCl per cc.), and double the theoretical amt. must be used. At first the acid must be heated with great care, the reaction being very violent on account of H_2 coming off. The soln. obtained may, after an addn. of Zn, be used as com. $ZnCl_2$. The main difficulty of this process is the necessity of operating in an app. resistant to HCl. A drawing of a suitable app. is given. Patents are applied for. BERNARD NELSON

Manufacture of potassium chloride from Solikamsk sylvite. F. F. WOLF AND V. S. YATLOV. *J. Chem. Ind.* (Moscow) **5**, 274–9(1928).—It has been shown previously (Volf and Yatlov, *C. A.* **22**, 3495) that fairly pure KCl can be obtained by crystg. Solikamsk sylvite from water, because the Mg salt content of the sylvinite is very small. However, by the repeated use of mother liquors for soln. and crystn. of new quantities of sylvite the former gradually become enriched by constantly increasing amts. of $MgCl_2$. V. and Y. studied the extent to which conditions of pptn. of KCl are affected thereby. Expts. show that increase of $MgCl_2$ content of the solns. up to 120 g. per 1000 g. H_2O has no influence on the speed of soln. of KCl and NaCl. The soly. of NaCl in satd. solns. of KCl which contain also a little $MgCl_2$ decreases with the increase of time, but it increases with temp. when the $MgCl_2$ content of the solns. is over 100 g. per 1000 g. H_2O. When the $MgCl_2$ content of hot solns. increases over the above limit NaCl is pptd. on cooling, even if they are satd. with KCl. When the $MgCl_2$ content of the solns. reaches the above limit it is practically impossible to obtain from them pure KCl, whether they are completely satd. with KCl or not. It follows that the presence of a considerable amt. of carnallite in sylvite renders the conditions of KCl extn. considerably more difficult. BERNARD NELSON

Natural nitrate of soda. A. L. *Rev. agr. Maurice* **5**, 113–6(1928).—A brief history of the Chilean nitrate industry, statistics of nitrate production, and comparative prices of the various N fertilizers are presented. F. W. ZERBAN

Lead compounds and magnesia. WEBSTER NORRIS. *India Rubber World* **78**, 55 7, 71–2(1928).—Their characteristics and uses are described. C. C. DAVIS

Mechanical developments in the potash industry. R. EHRHARDT. *Chem. Fabr.* 1928, 277–8.—The much larger outputs which are necessary to render potash manuf. profitable today have involved alterations in the methods of handling. Wagons of crude salt are now moved and tipped mechanically. The salt is broken in mills in which it falls upon beaters striking upwards. These produce grains of about 4 mm. diam. with little fines, and are built with through-puts of up to 250 tons per hr. With high outputs it is better to reduce to a certain size in beater mills and to finish the crushing with rollers. To ecomomize power, the feed to these secondary mills is passed through a vibrating sieve, one design of which is described. B. C. A.

Technic of the concentration of graphite by flotation. CHARLES BERTHELOT. *Chimie et industrie* Special No., 397–403(April, 1928).—A general description of the

flotation process as applied to the concn. of graphite ores, with a brief discussion of the cost of production in Canada and in the U. S. A. Papineau-Couture

The bromine industry in Alsace. C. Horst. *Chimie et industrie* **Special No.,** 404–5(April, 1928).—Brief outline of the process of extn. of Br in the Alsatian potash mines and of its possibilities of development with increased Br demand in the chem. industry. A. Papineau-Couture

Direction for polishing aluminum. O. G. Styrie. *Apparatebau* **40,** 174–5(1928).—Five formulas for polishes are given, with directions for producing various effects. J. H. Moore

Helium developments. R. R. Bottoms. *Chem. Markets* **23,** 250–2(1928). E. H.

Purification of helium. J. Williamson Cook. Bur. of Standards. *Phys. Rev.* **29,** 920(1927).—He contg. approx. 3% air with a trace of Ne and H_2 can be almost completely purified by passing it at a slow rate at atm. pressure over suitably treated cocoanut charcoal. Data are given for the absorption of air per g. of the charcoal at various temps. between —78° and —209°. W. W. Stifler

Preparation of hydrogen for military aeronautics. Jean Salomon. Univ. de Strasbourg. *Chimie et industrie* Special No., 406–7(April, 1928).—The requirements of a process suitable for use in the field in wartime are briefly discussed. Siemens and Schuckert in 1911 proposed the action of Si or Si alloys on alk. solns. according to the reaction $Si + 2NaOH + H_2O \longrightarrow Na_2SiO_3 + 2H_2$, which takes place slowly in the cold and requires a temp. of about 80° to proceed at a satisfactory rate. The process can be cheapened appreciably by using the resultant soln. to obtain an addnl. amt. of H_2 almost as great as that obtained in the 1st reaction, by adding to the still warm soln. a further quantity of Al alloy or scrap Al according to the equations: $Na_2SiO_3 + H_2O \rightleftharpoons SiO_2 + 2NaOH$; $2Al + 6NaOH = 2Al(ONa)_3 + 3H_2$. About 80% of the NaOH produced by the 1st reaction can be utilized in the 2nd reaction, complete utilization being prevented by the fact that when the diln. reaches a certain value the degree of hydrolysis of the Na_2SiO_3 falls to a very low value. In this way, the reaction of 1 kg. Si and 480 g. Al on 2.8 kg. NaOH gives 200 g. H_2 (or about 2240 l.). A. Papineau-Couture

The nitrogen industry. R. E. Slade. *J. Soc. Dyers Colorists* **44,** 265–8(1928).—A review is made of the development of the N industry of the world. Some details of the process of N fixation used by The Synthetic Ammonia and Nitrates, Ltd., at Billingham are given. This factory, which represents the British N industry, uses the Haber process with a pressure of 200 atms. The output is 235 tons of NH_3 per day. This is converted chiefly into $(NH_4)_2SO_4$ by means of the gypsum process which yields a chalk by-product of use in agriculture and in the cement industries. L. W. R.

Technology, uses and analysis of selenium. J. B. Krak. *Glass Ind.* **9,** 152–3 (1928). H. F. K.

The production and uses of tellurium. G. Malcolm Dyson. *Chem. Age* (London) **19,** No. 479, Met. Sect., 17–9(1928). E. H.

Wood charcoal as an adsorbent for gases. A. Magnus, E. Sauter and H. Kratz. Inst. für Phys. Chem. Frankfurt, a. m. *Z. anorg. allgem. Chem.* **174,** 142–4(1928).—The adsorption curves of CO_2 and SO_2 on wood charcoal at low equil. pressures (0–30 mm.) show anomalous curvatures. The magnitude of the effect depends on the previous history of the charcoal. Long-continued, high-temp. evacuation accentuates the effect. If the charcoal be boiled with HCl, and washed with boiling H_2O, the anomalous results are no longer obtained and the low pressure adsorption curves are linear. The anomalous results are best explained by assuming alkali or alkali-earth oxides as impurities in the untreated charcoals. The metal oxides are the source of the apparent higher adsorption potentials. R. L. Dodge

Rotating sulfur burners. W. F. Alewyn. *Arch. Suikerind.* **36,** 465–8(1928).—S contg. a large amt. of bituminous matter cannot be burned efficiently in the old-type burner. The Glens Falls Machine Works has constructed a rotary burner, similar to a granulator, which overcomes the difficulty mentioned; it has not been tried yet in Java. Expts. will be made with an old-type S burner into which is built a rotating cylinder, with the object of stirring the burning S. Both app. are illustrated. P. R. Pekelharing

Re-opening of the Chilean saltpeter mines. Constantin Redzich. *Apparatebau* **40,** 198–201(1928).—General remarks on modern methods and app. J. H. Moore

Colloid-technical general reviews. II. Plastics. Josef Obrist. *Kolloid-Z.* **45,** 82–92(1928).—The evolution of the plastics industries seems to take a course similar to that followed by the older rubber industry, developing first along strictly empirical

lines and only recently beginning to find a rational groundwork in colloid chemistry. Plastics are defined as materials that are horny and elastic at ordinary temp. but can be molded at higher temp. They include (1) cellulose plastics, (2) artificial resins and (3) protein plastics. Artificial silk, paper and varnish resins are excluded. After a discussion of "colloid nature and plasticity," each of the three classes of plastics is reviewed. There are about 100 literature citations. F. L. BROWNE

Dihydroxydiphenyldimethylmethane and its use in plastics. CHARLES W. RIVISE. *Plastics* **4,** 429–30, 448(1928).—The method of prepn. and the various applications of this compd. are discussed. The information given is taken from 11 U. S. patents that were issued to W. A. Beatty. FREDERICK C. HAHN

Effect of adding oxidants in the steeping process in bleaching. HALLER AND P. SEIDEL. *Z. angew. Chem.* **41,** 698–702(1928).—Contrary to earlier views it is shown that the addn. of oxidizing agents at the steeping stage in the process of bleaching is undoubtedly advantageous. Oxidizing agents, however, which readily give up their O in the alk. bath are to be avoided; the best results are obtained with "aktivin" (Na *p*-toluenesulfonchloroamide), which affords on hydrolysis neutral easily sol. products removable by washing. The use of such agents enables the bleaching to be conducted at lower pressures, and a steeping period of 4 hrs. serves instead of 6–8 hrs. as formerly. Satisfactory results are not obtained by steeping with lime alone; a further treatment with 2% NaOH soln. gives a well-bleached product. In the steeping process the loss in weight is proportional to the alkali consumed and the org. material dissolved, and the function of the oxidizing agent appears to be that of converting the impurities into products sol. in alkali. Microscopical examn. shows that the operation removes pectins and the cuticle incrustation without impairing the tensile strength of the material. Inferior results with lime alone appear to be due to the failure of this reagent to act on the cuticle. Oxycellulose is only formed to a slight extent as shown by the Cu numbers and "boiling-out" numbers of the steeped material. The best results are obtained with a bath contg. about 10% of aktivin (corresponding to 2% of "active" Cl) and 2% NaOH soln. For the tests, crude cellulose from nettles, which gave no starch reaction with I, was used. B. C. A.

Removing dried ink from vulcanite fountain pens. R. DITMAR. *Chem.-Ztg.* **52,** 123(1928).—The greenish gray discoloration caused by prolonged immersion in water or aq. solns. to remove dried ink may be avoided by using a soln. of $Na_2S_2O_4$, which effects a rapid cleaning without affecting the vulcanite. B. C. A.

The most important metal stains. H. KRAUSE. *Apparatebau* **40,** 172–4(1928).—Formulas are given for staining Fe, Ag and Cu and its alloys, with directions. J. H. M.

Technological notes [removal of CO_2 from gases for NH_3 synthesis] (NOVÁK) **21.** Carbon black. I. A study of its volatile constituents (JOHNSON) **30.** Apparatus for drying $(NH_4)_2SO_4$ crystals (Brit. pat. 283,717) **1.** Fertilizers and Mg salts (Brit. pat. 283,558) **15.** Water gas and H (Can. pat., 281,814) **21.**

Hydrochloric acid from waste liquors of fuller's earth manufacture. SIRIUS-WERKE A.-G. Ger. 464,086, July 26, 1928. The free acid in the waste liquors is neutralized with metals or compds. of metals whose chlorides yield HCl on thermal decompn. The waste liquors are evapd., *e. g.*, on drum driers, and the chlorides scraped off.

Synthesis of hydrocyanic acid. NORSK HYDRO-ELEKTRISK KVAELSTOFAKTIESELSKAB. Norw. 44,822, Feb. 6, 1928. A gaseous mixt. of N_2 and carbohydrates without any considerable amt. of CO is passed through an elec. high-voltage arc furnace preferably of the Birkeland-Eyde type with metallic walls which are cooled by water to a temp. not at any point exceeding 400°. The reaction gases which have a temp. of 400–600° are cooled in an app. designed for steam generation to a suitable absorption temp. and are then passed through an alk. absorption app. The residual gas is returned into the process in const. circulation. The strong cooling of the furnace walls is necessary to prevent the formation of soot.

Purification and drying of sulfur dioxide. AKTIESELSKAPET RAOUL PICTET & F. THARALDSEN. Norw. 43,929, April 29, 1927. The gaseous SO_2 to be dried and purified is passed through a spray of liquid SO_2 under reduced pressure. The H_2O is removed in the form of ice.

Treating asbestos ore. SAMUEL H. DOLBEAR (to Selective Treatment Co., Ltd.). U. S. 1,684,365, Sept. 11. Asbestos is sepd. in pencil-like form from assocd. rock, by an app. which is described. U. S. 1,684,366 specifies subjecting the ore to underwater treatment, loosening the asbestos and at the same time preserving its natural

length, causing the loosened asbestos to pass into a body of water adjacent the comminuting zone, and maintaining the loosened asbestos in suspension until overflowed. An app. is described.

Sulfuric acid. Walter A. Patrick and Ernest B. Miller (to Silica Gel Corp.). U. S. 1,683,694, Sept. 11. In the contact process, SO_2 and an O-supplying gas are brought into contact with a hard active mass of porous gel, such as silica gel, assocd. with a substance such as Pt which catalyzes the conversion of SO_2 to SO_3; the gel has pores of such size that it will absorb water vapor to such an extent as to contain at least 21% of its own wt. of H_2O when in equil. with H_2O vapor at 30° and a partial pressure of 22 mm. Hg.

Sulfuric acid. Hugo Petersen. Can. 283,515, Sept. 25, 1928. H_2SO_4 is manufd. from sulfurous gases, particularly from gases having a variable percentage of SO_2, by first treating the gases by any known contact process, and treating the remaining sulfurous gases in a second plant in which the SO_2 is oxidized by oxides of nitrogen, the second plant consisting of towers filled with a small acid-resisting packing material of high mechanical resistance, and rinsed with a soln. of nitrosylsulfuric acid in H_2SO_4.

Removal of arsenic from sulfuric acid. M. A. Kolontayev Russ. 1514, Sept. 15, 1924. Warmed crude H_2SO_4 is led through lead containers filled with porous material (coke, metallized pumice stone, etc.), which is a good elec. conductor; this acts as a cathode. Anodes are placed in cylindrical porous containers and these are placed in the cathode material. An elec. current passed through this system deposits metallic As or forms AsH_3, which escapes into the air.

Production of hydrogen and phosphoric acid. Norsk Hydro-Elektrisk Kvaelstofaktieselskab. Norw. 45,018, April 2, 1928. Phosphorus is oxidized by CO_2 under known conditions, the formed P compds. are removed from the CO-contg. gas, which is converted with steam to H_2 and CO_2, the latter being used again for the oxidation of new amts. of P under const. circulation. The process may be carried out in combination with the electrothermic production of P in the way that the CO_2 gas is introduced in the furnace before the condensation of the P vapors.

Bottles for hydrofluoric acid, etc. H. O. Traun (trading as Traun & Söhne vorm Harburger Gummikamm-Compagnie). Brit. 283,868, Jan. 18, 1927. Bottles or other containers are made from or covered with a phenol-CH_2O condensation product or other suitable artificial resin, preferably mixed with finely divided graphite, and are given a protective coating of "varnish or other material." The necks may have an external layer of hard rubber which may be screw-threaded.

Ammonia. Norsk Hydro-Elektrisk Kvaelstofaktieselskab. Norw. 43,786, March 7, 1927. In the same app. 2 different catalyzers are applied, the first one being very little sensitive to the effect of poisons and working irregularities and relatively little active, while the second catalyzer should be very active and may be more sensitive to poisons and working irregularities.

Ammonia. Norsk Hydro-Elektrisk Kvaelstofaktieselskab. Norw. 43,787, March 7, 1927. Hot gas is introduced at one or more places in the catalyzer chamber. When gas is introduced at 2 or more sep. places, the temp. is kept different in order to be able to maintain the most favorable temp. or temp. difference in the catalyzer.

Separation of ammonia from gas mixtures. Georg F. Uhde. Can. 283,221, Sept. 11, 1928. NH_3 is sepd. from gases, especially from a gas mixt. of N and H under pressure subjected to a catalyst, by evapg. under low pressure the liquid NH_3 sepd. from the previously cooled gas mixt. and leading it to meet the mixt. contg. NH_3 in counter current for the purpose of cooling it and adding new quantities of NH_3 to the gas mixt. to be cooled.

Catalyst for ammonia synthesis. Georg F. Uhde. Can. 283,222, Sept. 11, 1928. A catalyst contg. Fe, Al, C, N and alkali is treated in dry state in a catalyst furnace at a moderate temp. suitably under pressure with H or with H and N before it is used for the synthetic production of NH_3.

Catalyst for the manufacture of ammonia. Norsk Hydro-Elektrisk Kvaelstofaktieselskab. Norw. 44,446, Oct. 10, 1927. Natural magnetite is ground to slime and concd. by magnetic sepn. The concd. slime is treated with 50% HNO_3 to which has been added a minor quantity of HF. No more of the acid should be applied than is required for making a stiff paste. The mass is heated to 90–100° for 1 hr. while stirring. Then water is added till the concn. of the acid has been reduced $^1/_2$, after which the mass is kept for 1 hr. at 100°. Then the acid is removed by washing and the gang and the formed sulfur are sepd. from the residue, which is eventually subjected to a magnetic sepn. The purified slime is fused in an elec. arc furnace with addn. of a suitable amt. of K Al nitrate. After cooling the mass is pulverized and filled into

the catalyzer chamber where it is reduced by gentle heating in a H_2-N_2 mixt. At a temp. of 500° under pressure this catalyzer will give a very high percentage of NH_3.

Apparatus for the synthesis of ammonia. NORSK HYDRO-ELEKTRISK KVAELSTOFAKTIESELSKAB. Norw. 44,823, Feb. 6, 1928. Structural features.

Hydrogen-nitrogen mixtures for the ammonia process. NORSK HYDRO-ELEKTRISK KVAELSTOFAKTIESELSKAB. Norw. 44,486, Oct. 17, 1927. A mixt. of H_2O and air is passed through glowing carbon, the required energy being applied in the form of elec. energy, the carbon mass in the generator acting as a resistor. The process is carried out at a lower temp. than the ordinary water-gas process.

Purification of hydrogen-nitrogen mixtures for production of ammonia. BIRGER F. HALVORSEN (to The Norsk Hydro-Elektrisk Kvaelstofaktieselskab). Can. 282,906, Aug. 28, 1928. H-N mixts. are purified by washing with a liquid NH_3 contg. inorg. salts (Cu_2Cl_2, NH_4NO_3) capable of reacting with H_2O, CO_2 and CO. ($Ca(NO_3)_2$, metal chlorides, cyanides and nitrates may be used.)

Purification of gases for the ammonia process. NORSK HYDRO-ELEKTRISK KVAELSTOFAKTIESELSKAP. Norw. 44,232, July 25, 1927. The mixt. of H_2 and N_2 is purified by means of org. or inorg. compds., for instance nitrates, suspended in liquid NH_3. Several different salts may be used simultaneously, each salt having a special purifying power.

Treating hygroscopic salts. NORSK HYDRO-ELEKTRISK KVAELSTOFAKTIESELSKAB. Norw. 44,289, Aug. 8, 1927. Hygroscopic salts, particularly $Ca(NO_3)_2$, are treated with acids such as H_2SO_4 or H_3PO_4 so as to form an insol. or difficultly sol. salt coating on the surface of the grains. The saltpeter is afterwards treated with a base, preferably gaseous NH_3 for neutralization of the free acid.

Alkali metal nitrates and nitrosulfonic acid. I. G. FARBENIND. A.-G. Brit. 283,771, April 25, 1927. In forming alkali metal nitrates by the action on alkali metal chloride solns. of HNO_3 or N oxides, residual N oxides escaping with the HCl formed are absorbed by H_2SO_4 (suitably under 6–20 atm. pressure) to form nitrosulfonic acid. Brit. 283,772 specifies forming alkali metal nitrates by reaction on chloride solns. with N oxides admixed with O-contg. gases under pressures up to 50 atm. (suitably at a temp. of 35°) and with use of solns. of such concn. that the nitrate formed is deposited in the solid state. Cf. *C. A.* **22**, 2815.

Oxide-free halide of a rare refractory metal. JOHN W. MARDEN and HARVEY C. RENTSCHLER (to Canadian Westinghouse Co., Ltd.). Can. 283,251, Sept. 11, 1928. As an example, an oxide-free *potassium uranium fluoride* is pptd. from a soln. contg. uranyl acetate, an alkali metal fluoride, HF and HCO_2H by exposing to ultra-violet light. The water of crystn. is removed from the ppt. by fusing with NaCl and KCl.

Lead salts. STANLEY C. SMITH. Can. 283,213, Sept. 11, 1928. Pure Pb salts of the acids of As, Sb, Cr, W, Mo or U are manufd. from $PbCl_2$ by satg. boiling H_2O with $PbCl_2$ and NaCl, pouring the hot soln. into an almost equal vol. of cold water, removing the pptd. $PbCl_2$ from the liquor, and washing it with H_2O, and then maintaining this $PbCl_2$ in suspension in a hot or boiling soln. in H_2O of a salt of the respective acid.

Metallic phosphides. WILLIAM KOEHLER. Ger. 463,840, July 19, 1928. Finely divided metals, *e. g.*, Cu, are mixed with finely divided or dissolved white or red P and heated before or after compression, with or without admixture of lubricating agents, *e. g.*, graphite. Cf. *C. A.* **22**, 1219.

Alumina. METALLBANK UND METALLURGISCHE GES. A.-G. Brit. 284,131, June 7, 1927. Disintegrated alumina suitable for use in producing Al by electrolysis in a fused cryolite bath is obtained by disintegrating fused alumina and rapidly cooling the disintegrated material by water or other liquid. An app. is described.

Alumina. J. C. SEAILLES. Brit. 283,509, Jan. 11, 1927. A hydrated alk. earth. aluminate is prepd. as described in Brit. 277,697 (*C. A.* **22**, 2142) by treating a mixt. of Al ore and an alk. earth base with water under normal or increased pressure, but using 4 mols. of the base to 1 mol. of alumina, and preferably with 2–3 mols. addnl. base for each mol. of silica in the ore. The mixt. is preferably treated in a colloid mill in an autoclave under pressure. By suitable further addn. of a base such as lime and prolonging the treatment more silica is withdrawn as insol. Ca silicate and aluminosilicate. Ca aluminate formed is washed and treated with NaOH and preferably also with CO_2 to form Na aluminate and $CaCO_3$, and alumina is pptd. from the Na aluminate soln. by adding cryst. alumina.

Manufacture of alumina. AKTIESELSKAPET NORSK ALUMINIUM COMPANY. Norw. 44,305, Aug. 15, 1927. Alumina with a low content of SiO_2 is extd. from aluminous [illegible] and similar materials by treating with a soln. contg. approx. 80 g. per l. of

alk. Na compds. calcd. as Na_2CO_3, about 10% of which is present in the form of free NaOH. Some Na aluminate may also be present in the soln. Cf. *C. A.* **21,** 2362.

Aluminum chloride. RICHARD J. DEARBORN (to The Texts Co.). Can. 283,609, Sept. 25, 1928. $AlCl_3$ is made by continuously and simultaneously coking and purifying a mixt. of Al ore and carbonaceous material by heating and chlorinating at a relatively low temp. under conditions that no substantial chlorination of Al occurs, and then without loss of heat chlorinating the purified coked mixt. at a relatively high temp.

Nickel and cobalt carbonyls. LEO SCHLECHT and EMIL KEUNECKE (to I. G. Farbenind. A.-G.). Can. 283,414, Sept. 18, 1928. Co and Ni carbonyls are produced by roasting Co speiss with air and steam and treating with H at 400°, then leaching the product with $(NH_4)_2CO_3$ soln. satd. with gaseous NH_3, expelling the NH_3 by heating, and pptg. the metals in the form of their hydroxides and basic carbonates by diln., thereupon reducing the product with dry H at 350°, and treating the metal thus obtained with CO at 150° under a pressure of 200 atm.

Green hydrated chromium oxide. KURT H. MEYER and HANS KRZIKALLA (to I. G. Farbenind. A.-G.). Can. 283,413, Sept. 18, 1928. Green hydrated Cr_2O_3 is produced by treating a soln. of a compd. of sexivalent Cr at a temp. above 200° and at a pressure above atm. but below 150 atm. with a reducing agent other than H_2SO_3.

Lead oxides. J. J. TARDAN (to Consortium Electro-Chimique de France). Brit. 283,898, Jan. 19, 1927 A paste of spongy finely divided Pb as obtained by electrolysis is slowly dried at a temp. which is progressively raised to about 200° previous to being roasted to obtain Pb_3O_4. A mixt. of PbO and PbO_2 is obtained by the drying operation and it is stated that by suitable control of the conditions of roasting PbO or Pb_3O_4 may be obtained. An app. is described.

Production of nitrogen oxides with simultaneous oxidation of phosphorus. NORSK. HYDRO-ELEKTRISK KVAELSTOFAKTIESELSKAB. Norw. 44,444, Oct. 10, 1927. P is burned in air or mixts. of O_2 and N_2 under such conditions that N oxides are formed. The resulting gases are passed through hot H_2O or H_3PO_4 to absorb the P_2O_5 formed after which the N oxides are absorbed in known ways. The oxidation of the P may be carried out in elec. arc furnaces, the intention being to utilize the increased temp. obtained by the oxidation of P for improving the yield of the N fixation process. The process may be carried out under pressure.

Hydrogen peroxide. I. G. FARBENIND. A.-G. (Carl Miller and Leo Schlecht, inventors). Ger. 464,288 August 2, 1928. A large gas space is used in the prepn. of H_2O_2 by electrolytic reduction of oxygen, to avoid danger in explosions.

Hydrogen peroxide. HERMANN SCHULZE. Ger. 464,353, Aug. 1, 1928. Ba, Ca or Sr hydroperoxide obtained electrolytically is treated, with stirring and cooling below 0°, with HCl and H_2SO_4, or with CO_2 and finally with H_2SO_4, or periodically or continuously with concd. H_2SO_4. The soln. obtained is evapd. on a surface evaporator at ordinary or reduced pressure.

Active carbon. E. BERL. Brit. 283,968, Jan. 21, 1927. Active C is obtained from water-sol. and other acid esters such as those resulting from the purification of petroleum and coal-tar products with H_2SO_4. The esters are neutralized with alk. substances such as KOH, K_2CO_3 or K sulfide and evapd. to dryness, heated to 300–400° to remove S and S compds. and neutral oils, and then heated to a higher temp. with activating gases or vapors and cooled in an inert gas or by quenching with water.

Active carbon. I. G. FARBENIND. A.-G. (Fritz Winkler, inventor). Ger. 463,772. July 19, 1928. Active C is prepd. by action of hot gases on carbonaceous materials in a blast furnace.

Active carbon. SOC. DE RECHERCHES ET D'EXPLOITATIONS PETROLIFERES. Brit. 283,573, Jan. 14, 1927. Before or at the time of activation of C by gases at high temp., the C is impregnated with 1–5% of acids, bases or salts such as H_3PO_4, alkali phosphates, H_3BO_3, a borate, carbonate, bisulfate or silicate of Na or NaOH, which may modify the heat-resisting properties of the material or serve as fireproofing agents. The material may be agglomerated or molded with various specified binders. A light, black and soft decolorizing C may be obtained by impregnating wood charcoal with small quantities of $FeCl_3$, $ZnCl_2$ or HCl, or by washing with acid to remove ash, and then activating. The ash may be washed out of the various products before or after activation, by use of water and acid, or may be volatilized at high temps. after activation.

Activated carbon. I. G. FARBENIND. A.-G. Brit. 283,485, Jan. 10, 1927. In activating C, the material is treated in a thin layer (suitably 5 cm. deep) on a stationary or moving support with an activating gas or vapor which may be passed over the layer or supplied through a diaphragm. An annular kiln with a rotating ring may be employed for carrying out the process in a continuous manner.

Pure carbon. DANIEL GARDNER. Can. 282,782, Aug. 28, 1928. Fine charcoal powder is treated with concd. HNO_3 in presence of H_2SO_4 and subsequently washed repeatedly with H_2O. It is then subjected to further acid treatment with a mixt. of concd. HNO_3 and concd. HCl at about 75° to 80°, the operation being accompanied by continuous stirring. The resulting soln. is decanted and the product thoroughly washed. It is then treated with concd. alk. soln. (as 6 *N* NaOH) and afterwards well washed. The very pure carbon obtained is now heat-treated at 1000°–1300° in a neutral atm., under vacuum, or in a reducing atm. or a gas free from O, to obtain the velvet black tint characteristic of "carbon black."

Hydrogen. JULIEN BELLAY. Can. 282,952, Sept. 4, 1928. Water gas is produced by gasification of coke, lignite, turf and other fuel rich in C without admission of outer air, within a generator heated from the outside, into which superheated steam is blown. The gas produced is enriched in H by causing it to flow through a column forming an extension of the lower generator with adjustable heating and having partitions of fire-proof clay and coal and blowing into the column superheated steam at 100° to 400°. The enriched gas is brought into a known purifier and condenser contg. lime milk in which the CO_2 and coal dust and impurities are sepd., the remaining gases being brought to a purifier heated from outside and filled with a fresh prepn. of soda-lime and completely retaining all the CO and CO_2 still remaining in the H. The pure H is passed to a gasometer.

Removal of phosphorus from gas mixtures. W. REICHENBURG. Ger. 464,351, Aug. 2, 1928. P is removed from gases by silica gel with or without the addn. of oxides or salts of Fe, Ni, Co, Cr, Mn, V, Mo, or Ce. The SiO_2 gel may be partially or wholly replaced by gels of the oxides of Al, Fe, Zr, Sn, or Ti, with or without the above additional substances.

Sulfur. JAMES W. SCHWAB (to Texas Gulf Sulphur Co.). U. S. 1,683,731, Sept. 11. The color of abnormally colored sulfur is improved by treating it while molten with finely divided activated C and then sepg. the materials, *e. g.*, by settling or centrifuging. Cf. *C. A.* **22**, 1019.

Continuous precipitation of sulfur from solutions. I. G. FARBENIND. A.-G. Ger. 463,138, July 5, 1928. Addn. to Ger. 462,092. Solutions of S in low-boiling solvents such as CS_2, obtained from gas purifiers and contg. tar are added to a solvent which is held at a temp. above the b. p. of the low-boiling solvent but below 120°. Tetralin and $C_2H_2Cl_4$ are suitable.

Green corundum. ANTON KRATKY. Austrian 108,704, Sept. 15, 1927. Green corundum (oriental emerald) is obtained by fusing pure Al_2O_3 with a trace of a mixt. of CoO and ZnO, preferably with the addn. of a flux, at a temp. sufficiently low to avoid volatilization of the coloring addn.

Condensation products of aniline with formaldehyde, etc. SOC. ANON POUR L'IND. CHIM. À BÂLE. Brit. 283,965, Jan. 21, 1927. Porous masses of condensation products are densified by use of heat and pressure, *e. g.*, by subjecting to 100 atm. pressure at 150° for about 1 hr.

Phenol-formaldehyde condensation products. GRIGORI S. PETROV and PETER SHESTAKOV. U. S. 1,684,142, Sept. 11. Prepn. of condensation products such as those from cresylic acid or "com. carbolic acid" and CH_2O is effected in the presence of powd. metals, *e. g.*, Pb or Zn, which serve as catalysts.

Artificial horn articles. ADALBERT ZSIGMONDY. Can. 283,383, Sept. 18, 1928. Molded articles from artificial horn (particularly gluten horn substitute from casein and the like) is produced by cutting up pieces from unhardened artificial horn, hardening said pieces, distributing said pieces in a plurality of molds, compressing said molds, at a pressure of about 400 to 500 atm. and temp. of 90° to 100°, and cooling the heated finished pieces.

Cleaning composition. I. B. MÖLLER. Norw. 43,782, March 7, 1927. A mixt. of 55% of sawdust, 5% casein, 10% sodium soap and 30% kieselguhr.

Cleaning and polishing compound. WILLIAM RICHTER. Can. 282,819, Aug. 28, 1928. A cleaning and polishing compd. contains distd. water 57 1/4 oz., light separator oil 18 3/4 oz., turpentine 18 3/4 oz., white wine vinegar 18 3/4 oz., butter of antimony 4 oz., and amberglaze 10 3/4 oz.

Cleaning and polishing compound. CHARLES H. MCALEER, Can. 282,808, Aug. 28, 1928. A cleaning and polishing compd. contains a powdered abrasive, stearic acid, Japan wax, kerosene and a light rubbing oil practically free from paraffin. Cf. *C. A.* 22, 1447.

Polishing composition. THORVALD AASERUD. Norw. 44,660, Nov. 28, 1927. One l. of benzine, 0.3 kg. zinc white and 0.05 kg. lampblack are mixed carefully.

Detergent compositions. KARL TUCEK. Austrian 108,687, Sept. 15, 1927. Detergent compns. (for metal, glass, wool, etc.), comprising a suspension of $CaCO_3$ in EtOH or an alc. soln., are improved by addn. of camphor, suitably in amts. of 1 to 10%.

Manufacture of urea and products containing urea in connection with the manufacture of alumina. E. JOHNSON. Norw. 44,060, Dec. 27, 1927. The mass obtained by decompn. of materials contg. Al_2O_3 with acids is treated with a soln. of cyanamide. The cyanamide will be hydrolyzed to urea at the same time as the Al salts are obtained in the soln.

Impregnating and adhesive compositions. WILHELM PUNGS (to I. G. Farbenind. A.-G.). Can. 282,877, Aug. 28, 1928. Stearin pitch 130 parts, 20 parts of wood oil, 50 parts of whale oil and 45 parts of S are heated at 160° and stirred until a viscous mass, which becomes dry when cold, is formed. To this is added 60 parts of tar ext. obtained by treating brown coal tar with 90% alc., and the fluid product is heated until the desired degree of viscosity is attained. The product is of great value for the impregnation of textile materials, papers, pasteboard or in the manuf. of cables or insulating masses.

Gel formation. JAMES W. MCBAIN (to Grinnell Jones to S. Sternau and Co., Inc.). Can. 283,095, Sept. 4, 1928. A dispersed substance, *e. g.*, nitrocellulose is dissolved in anhyd. EtOH at sub-zero temp. Gellation is caused by increasing the temp. to about normal atm. temp.

Increasing the adsorptive powers of silica gel. I. G. FARBENIND. A.-G. Ger. 463,227, July 5, 1928 (Hans Carstens and Gerhard Kröner, inventors). Acid-pptd. silicic acid gels are washed with alk. solutions, *e. g.*, of Na_2CO_3, NaOH, NH_3, water glass, org. bases, etc.

Roasting kieselguhr containing organic material in mechanical roasting ovens. RICHARD KOECH. Ger. 462,992, June 28, 1928. Mechanical details of the process.

Heat-generating compound. JOHN R. DULANY (to The Chamberlain Co.). Can. 283,402, Sept. 18, 1928. A heat-generating compd. is composed of dry caustic alkali, Al, Al_2O_3, SiO_2 and other impurities contained in Al dross.

Preheating catalyst furnaces. GEORG F. UHDE. Can. 283,220, Sept. 11, 1928. Catalyst furnaces and the catalyst bodies therein for the purpose of effecting the synthesis of NH_3 are preheated by heating the mixt. of gas under pressure before it enters the reaction furnace (by an outer source of heat) to a moderately high temp. and the heat accumulated therein is afterwards communicated to the said reaction furnace and the catalyst bodies.

Coloring granular slate. HARRY C. FISHER (to The Richardson Co.). Can. 283,295, Sept. 11, 1928. Granular slate is colored by immersing it in a bath of dissolved hydrated sulfate of a desired metal (Cu), then boiling to or near dryness, then firing to convert the sulfate to an oxide of the metal, then immersing the slate in a bath of hydrated $FeSO_4$, boiling to or near dryness, and firing a second time to convert the $FeSO_4$ to oxide and form ferrites of the metal oxide, the color varying upon the excess of either oxide. Cf. *C. A.* **22**, 3747.

Coloring granular slate. HARRY C. FISHER (to The Richardson Co.). Can. 283,296, Sept. 11, 1928. Slate granules are colored by intimately mixing with an Fe salt and a Cr salt and roasting so that the Fe will pass through a hydroxide state, and then further roasting the granules to change the Fe into an oxide state.

Coloring granular slate. HARRY C. FISHER (to The Richardson Co.). Can. 283,297, Sept. 11, 1928. Granular slate is colored by mixing it with a pigment material and sol. silicate, and rapidly roasting the granules to bring about a puffy opaqueness of the siliceous mixt. and subsequently heating the granules to change the physical characteristics of the puffy opaque siliceous mixt., the heating being accompanied with agitation.

Asbestos paper. WILLIAM NANFELDT (to World Bestos Corp.). Can. 283,449, Sept. 18, 1928. Asbestos paper adapted for use in yarn manuf. is made by forming a pulp of asbestos, treating rosin to render it miscible with water and to form a binder which will substantially retain its strength when the resulting paper is wet, incorporating the binder thus formed with the pulp, and forming asbestos paper from said pulp and binder.

Match splints formed of paper pulp reinforced by metal wire. GEORGE A. TAYLOR. U. S. 1,684,000, Sept. 11.

Transferring pictures from paper to celluloid. C. GLASER. Brit. 283,571, Jan. 14, 1927. Transfer is effected by use of solvents, etc., so as to produce pictures held between sheets of celluloid and which have somewhat the appearance of oil or water color paintings.

Masking composition. William A. Brewer and P. Dean Jackson. Can. 283,454, Sept. 25, 1928. A masking compn. to protect a portion of a surface to be coated comprises a mixt. of glycerol 16 parts, whiting 32 parts and water 1 part, with a small addition of an essential oil and a coloring matter.

Button board. Albert L. Clapp (to Beckwith Mfg. Co.). U. S. 1,683,605, Sept. 11. A material suitable for making buttons, sound records, etc., is made by disintegrating and beating waste paper, wood pulp or other suitable cellulosic material in water, together with a mech. comminuted resinous gum such as rosin, shellac, copal or sandarac and a suspension medium such as starch and lime and forming the resulting pulp into shape, *e. g.*, by heat and pressure.

Paint remover. Fred C. Dean. Can. 283,159, Sept. 11, 1928. A compn. for removing paint and varnish contains a pure benzene spirit, crude benzene or coal tar naphtha, paraffin wax, ceresin wax, and methylated spirit.

Amalgams for filling teeth. E. W. Fischer and E. W. J. Virgin. Brit. 283,488, Jan. 10, 1927. Particles of alloying metals such as Sn or Ag and Sn are given a preliminary coating of Hg to assist in amalgamation with addnl. Hg added by the dentist. A hot soln. of $HgCl_2$ and dil. HCl may be used for the preliminary coating.

19—GLASS, CLAY PRODUCTS, REFRACTORIES AND ENAMELED METALS

G. E. BARTON, C. H. KERR

Report of the Glass Workers' Cataract Committee. J. R. Bradford, *et al.* *Proc. Roy. Soc.* (London) **B103**, 192–207(1928).—Glass workers' cataract is not due to the action of luminous radiation or x-rays, and probably is not due to the direct action of ultra-violet or infra-red rays. It may be due to an indirect action on the nutrition of the lens, caused by the deleterious action of the infra-red rays on the iris and ciliary body. Cataract, indistinguishable from glass workers' cataract, occurs in tin plate rollermen, chain makers, and puddlers. Joseph S. Hepburn

Renaissance glass. Walter Butterworth, Sr. *J. Soc. Glass Tech.* **12**, 119–28 (1928); cf. *C. A.* **22**, 2646.—An illustrated discussion of the development of stained glass art. H. F. K.

Some recent improvements in the manufacture of flat glass. H. K. Hitchcock. *Glass Ind.* **9**, 105–9(1928); cf. *C. A.* **22**, 2249. H. F. K.

Breaking strength of glasses as a function of the composition. Oscar Knapp. *Glass Ind.* **9**, 78–80; *Glass Industrie* **35**, 245–7(1928).—Special glasses for chem. ware gave values in thermal and mech. shock tests quite in agreement with Winkelmann's formula: $W = P/aE \sqrt{k/S\,c}$, where W = thermal strength, P = tensile strength, a = expansion, E = elasticity, k = thermal cond., S = sp. gr., and c = sp. heat. H. F. K.

Use of barite in soda lime flint glasses. D. J. McSwiney. *Glass Ind.* **9**, 97–9 (1928).—Barite appears to serve well in facilitating melting and refining of the batch—improving the annealing properties, the brilliancy and weathering resistance of the glass. Some 500 tons per month are used in this country. H. F. K.

Experiments on the acceleration of glass melting by the use of volatile constituents in the batch mixture. W. E. S. Turner. *J. Soc. Glass Tech.* **12**, 134–8(1928).—The addn. to the batch of NH_4Cl, NH_4NO_3 and $(NH_4)_2SO_4$ in amts. up to 1% of the sand wt. increased the melting rate. The NH_4Cl and $(NH_4)_2SO_4$ also increased the refining rate, especially in pot furnaces. $(NH_4)_2SO_4$ proved best in these respects and did not produce color defect or seediness. H. F. K.

Some notes on accelerating the melting of glass. R. Hemingway. *J. Soc. Glass Tech.* **12**, 131–4(1928).—In parallel tanks, one producing colorless glass, the other amber it was noted that the melting rate of the amber glass was greater by 50%. The only difference in the 2 batches was the S in the amber glass. Conclusion: The stirring action produced by the gaseous compds. of S during the heating increased greatly the melting rate of the batch. H. F. K.

Density control of glass tanks. A. R. Payne. *Glass Ind.* **9**, 121–5(1928).—A density change indicates a change in compn. of the batch. As a control method it can be used to supplement chem. analysis. H. F. K.

Some remarks on glass-house pots. Percival Marson. *J. Soc. Glass Tech.* **12**, 141–6(1928). H. F. K.

Designing glass-forming molds. Roy E. Swain. *Glass Ind.* **9,** 148–51(1928). H. F. K.

Electrolytic chromium plating of glass molds and cylinder materials. Kurt Illig. *Glastech. Ber.* **5,** No. 6(1927); *Glass Ind.* **9,** 31–5(1928).—The factors encouraging the Cr plating of molds, etc. are added permanence of the molds without loss in definition and detail, or need of changed design, and at relatively low cost. H. F. K.

Aspects of bottle machine operations. B. M. Pearson. *Glass Ind.* **9,** 143–8 (1928). H. F. K.

Control and distribution of temperature in lehrs. A. Cousen, H. W. Howes and F. Winks. *J. Soc. Glass Tech.* **12,** 146–58(1928).—To det. satisfactorily the heat distribution within lehrs a pyrometer was devised which could travel down the lehr on the belt beyond the crit. zone. Couples of eureka-stainless iron and nichrome–Kromore were found suitable. Graphs of the temps. found in several types of lehrs are given. H. F. K.

Unique lehr. Arron. *Glass Ind.* **9,** 99–103(1928).—Illustrated discussion of the Dixon fuelless lehr which anneals with the heat of the ware. H. F. K.

Design and operation of glass furnaces. W. W. Warren. *J. Soc. Glass Tech.* **12,** 128–31(1928).—Discussion of the radiation and other heat losses, and some factors affecting the output of furnaces. H. F. K.

Apparatus for recording the glass level in a tank furnace. J. W. Ball and C. G. Eden. *J. Soc. Glass Tech.* **12,** 138–40(1928).—The app. is described in a detailed drawing. It consists of a siphon with a float moving an arm vertically which in turn operates indirectly a needle on a continuous recording graph. H. F. K.

Design of plate glass polishing machines. F. W. Preston. *Glass Ind.* **9,** 27–9, 57–9, 81–4(1928).—The glass removed during polishing is a measure of the work done on it. The arrangements of the felts of the polisher must avoid localized over heating and cut away the glass as uniformly as possible. Patterns of the felts and the profile of their cuts are shown. H. F. K.

Study of the casing of clear opal glass. The importance of annealing. Francis Winks and W. E. S. Turner. *J. Soc. Glass Tech.* **12,** 161–4(1928).—It was possible to unite 2 com. glasses, one clear and the other opal, by slow annealing at just below the upper annealing temp. of the clear glass even though this temp. was 53° lower than the upper annealing temp. of the opal glass. H. F. K.

Some conclusions which can be drawn from the measurement of the expansion of glasses by means of the Chèvenard dilatometer. Emilio Damour and G. Thuret. *Chimie et industrie* Special No., 436–8(April, 1928).—See *C. A.* **22,** 671. A. P.-C.

A new washing process [for clays]. V. Busch. *Tonind. Ztg.* **52,** 1527–8(1928).—The customary method of washing clays requires too much space. An equipment which is capable of doing the same work is described. The clay is first blunged with water and the suspension thus formed is passed through a series of tanks similar to elutriators. H. G. Schurecht

Controlling the sand contents of clays and bodies by means of data obtained with elutriation tests. H. Harkort. *Ber. deut. keram. Ges.* **9,** 189–202(1928).—H. classifies the SiO_2 into coarse, medium, and fine sand and with the aid of elutriation tests keeps the fineness as well as the percent SiO_2 fairly const. in ceramic bodies. H. G. S.

Investigations of sagger clays. H. Kohle. *Ber. deut. keram. Ges.* **9,** 57–69(1928).—Saggers made with a washed kaolin and fine grog lasted about 25% longer than those made of sandy fire clay and grog. H. G. Schurecht

The use of Wildstein-Neudorfer sagger clay, brand "M," as raw material for the manufacture of saggers. R. Rieke. *Sprechsaal* **61,** 159–60(1928).—Chemical analysis: SiO_2, 50.85%; Al_2O_3, 43.03%; Fe_2O_3, 1.30%; TiO_2, 1.17%; CaO, 0.22%; MgO, 0.10%; alkalies K_2O, 2.48%; ignition loss, 10.40%. Coeff. of expansion: Between 20° and 300°, 20 × 10^{-7}; 300° and 500°, 40 × 10^{-7}; 500° and 600°, 35 × 10^{-7}; 600° and 800°, 27 × 10^{-7}. Rational analysis is given as 88.16% clay substance; 6.7% free quartz and 5.14% feldspar. Softening temp. is Seger cone 34–35. The material is very fine grained, 96% passing a sieve having 10,000 openings per sq. cm. After burning at cone 010a the porosity is 38.1%; at cone 15, 5.9%. R. A. Heindl

Plasticity of clays. A. Simon and W. Vetter. *Ber. deut. keram. Ges.* **9,** 216–28 (1928).—The capillary properties of clay are studied by means of vapor-pressure measurement of the clays with different water contents. Clays having the finest capillary pores have the lowest vapor pressures. H. G. Schurecht

Observations on the causes of the plastic conditions of clay. Herman Salmang. Tech. Hochschule, Aachen. *Sprechsaal* **61,** 115–6(1928); cf. *C. A.* **22,** 1222.—A re-

view of the various theories with especial reference to surface tension and adhesion and the plasticity of other masses that do not contain clay. R. A. HEINDL

Firing of clays in presence of water vapor and sulfur dioxide. J. KONARZEWSKI AND B. KRYNSKI. Polytech., Warsaw. *Przemysl Chem.* **12**, 176–84(1928).—The effect of water vapor and SO_2 on the progress of dehydration of china clay was studied. Up to 550° water vapor retarded dehydration, but above 550° it has practically no effect. SO_2 did not influence dehydration. Al_2O_3 and Fe_2O_3 in this clay fired at 550–800° could be dissolved by heating with HCl. Clays fired in the presence of SO_2 combine small quantities of it. The sulfates of Ca, Mg, Al and Fe are formed. The combined S can be removed completely by firing the clay in an oxidizing atm. A. C. Z.

Factors governing the durability of clay building materials. W. ANGUS MCINTYRE. Building Research Sta. *Brit. Clayworker* **37**, 195–205(1928).—Texture is important but the main factor is the crystn. of sol. salts, mainly sulfates. The expansion resulting from hydration of some of the salts produced is partly responsible for disintegration. Frequent washing tends to prevent the action. R. A. HEINDL

Science in the brick industry. R. RIEKE. *Tonind. Ztg.* **52**, 1459–61(1928).—More scientific aid is required to solve the problem relative to drying and firing of brick. H. G. SCHURECHT

Mineral constituents and origin of a certain kaolin deposit near Spokane, Washington. G. A. GOODSPEED AND A. A. WEYMOUTH. *J. Am. Ceram. Soc.* **11**, 687–95 (1928).—The kaolin occurs in unusual dikes. The evidence points to endomorphic action or perhaps even direct primary origin. C. H. KERR

Progress in refractory materials. C. J. VAN NIEUWENBURG. *Intern. Congress Testing Materials* **1927**, II, 359–64. E. H.

Practical experience of firing refractory materials with oil. FRANK WEST. *Trans. Ceram. Soc.* (England) **27**, 104–21(1928). H. F. K.

Physico-chemical principles of grinding materials. WILHELM EITEL. *Z. Ver. deut. Ing.* **72**, 1155–7(1928).—Not only hardness, but cleavage, tensile strength, brittleness, structure and other properties must be considered in detg. the value of grinding materials. The crystn. of a material from its molten state must be controlled carefully so as to produce the form of abrasive desired; this necessitates the use of correct phase diagrams. The binding materials used are of great importance also. Although artificial diamonds have not been prepd. on a large scale this is no proof that they may not be available in the future, for other problems seemingly as difficult have been solved. The influence of SiO_2, MgO, CaO, etc. on the compn. and properties of the crystals or mixed crystals produced in making alundum and other forms of Al_2O_3 is shown by diagrams and photomicrographs. In SiC the form of the crystal lattice is important in fixing the properties of the abrasive. Although the materials known to make good abrasives are few in number new substances showing promise of usefulness include certain Al silicates, W carbides, etc. W. C. EBAUGH

Structural research on hard porcelain. O. KRAUSE. Porzellanfabrik. Kahla, Freiberg, Saxony. *Z. tech. Physik* **9**, 247–63(1928).—For the manuf. of hard porcelain are used: I "clay" substance (or kaolinite) $Al_2O_3.2SiO_2.2H_2O$, which is plastic and loses H_2O and decomposes from 300° up, forming more HCl-sol. Al_2O_3. At 800° this decompn. is finished. At 1200° and above a new compd. seems to be formed. A time heating curve shows at 570° an endothermic, at 950° an exothermic, effect. II quartz, with the α-β (575°) transformation and those of tridymite and cristaobalite, III feldspar, consisting mostly of orthoclase and a little albite, the former m. 1200° and partly transforming into cryst. leucite m. 1100°. From these data the characteristics of the porcelain (av. 50% I, 25% II, 25% III) can be derived. The end product is in the heterogeneous system Al_2O_3–SiO_2–K_2O (or Na_2O). Complete bonding of Al_2O_3 and K_2O can be assumed with up to 20% free SiO_2. Heterogeneous equil. is only partly reached. The compn. attained is probably parallel to the Al_2O_3–SiO_2 side of the triangular diagram and the substance will have a fusing curve similar to that of Al_2O_3–SiO_2, allowing for a depressing influence of the alkali. It is therefore to be expected that ideal porcelain is a glassy mass with crystallites of mullite ($3\,Al_2O_3.2SiO_2$) and tridymite. These views were tested by x-ray work. Samples, finely pulverized, were illuminated with $CuK\alpha$ light (4 to 5 hrs.), the results being calcd. by Braggs relation. Expts. on kaolin (SiO_2 45.34%, Al_2O_3 37.93%, ignition loss at 1000° 13.92%) showed that this substance dried at 200° gives a diagram identical with that of natural nakrite (Freiberg); on heating at higher temps. more and more lines disappear. At 600° the original lattice is practically gone (no macroscopic change), leaving only a few of the strongest lines (amorphous). A second change appears at 1000°, showing recryst. and mullite formation, proportional to the kaolinite content. To confirm this point (Bowen and Greig),

disputed by Rosbaud (*C. A.* **20**, 3105.), the crystal needles from a kaolin melt were compared with natural (Delaware Co., Pa.) sillimanite ($Al_2O_3.SiO_2$). The similarity is incomplete; the reflection angles φ of "mullite" are on the av. 0.15° smaller than those of sillimanite (more than the limit of error) and always equal to those found for the needles in porcelain (one exception, unexplained, of sillimanite needles was found in an a. c. spark plug porcelain). Conclusion: The crystals formed on burning of ceramic masses are silicates with a lattice distorted (widened) by added Al_2O_3; it may be called mullite. X-ray pictures of burned porcelain (German and American) showed mullite to be present in all to a greater extent than previously assumed. Three groups of porcelain are distinguished: (1) poor in mullite; rich in quartz; (2) av. in both; (3) rich in mullite, poor in quartz. The mechanically strong porcelains (motor insulators, power line insulators) seem to belong to group 1. The second group is of av. quality; the 3rd group is that of the farthest advanced equil. (Staatliche Porzellan Manufaktur) and shows the best resistance against temp. changes. The Gilchrest and Klinefelter criteria for elec., thermal and mech. resistance as related to compn. (*Electric J.* **1918**, 36, 77) were confirmed. Diagrams are shown of porcelain mass burned to various temps. from 625° to 1410° in which the gradual disappearance of feldspar and quartz, and the appearance of tridymite and mullite can be traced. Rieke's work on this subject (*C. A.* **21**, 997) is discussed. For the formation of the mullite crystals it is assumed that submicroscopic crystals are formed below the formation point of the liquid phase. On further heating they partly dissolve in the latter and later on sep. out after satn. of the melt with SiO_2. B. J. C. VAN DER HOEVEN

Annealing of glazes. W. STEGER. *Ber. deut. keram. Ges.* **9**, 203–16(1928).—S. measures the annealing temp. of glazes by heating glazed bars in an elec. furnace and noting the deflections of the bars. When the bar is first heated it bends as a result of strains between the glaze and body. When it is heated to the annealing temp. of the glaze the bar ceases to bend because the glaze now is viscous and therefore no longer exerts strains between it and the body. H. G. SCHURECHT

Danger to health of antimonial enamels. B. REWALD. *Z. angew. Chem.* **41**, 287–8 (1928).—A criticism of the conclusions of Flury (*C. A.* **22**, 1622). Stress is laid on the innocuous character of Na metantimonate and compds. of quinquevalent Sb generally. In a rejoinder Flury points out that compds. of quinquevalent Sb may be reduced in the actual process of manuf. of the enamel, and that enamels made from such compounds have in fact been shown to yield salts of tervalent Sb, when subjected to acid solns. B. C. A.

Glass. MAX THOMAS (to Patent-Treuhand-Gesellschaft für elektrische Glühlampen m.b.H.). U. S. 1,684,332, Sept. 11. See Brit. 256,189 (*C. A.* **21**, 2946).

Electric glass furnace. BJÖRN RAEDER. Norw. 44,661, Nov. 28, 1927. Mech. features of design and operation.

Apparatus for conveying the fused glass mass from the melting furnace to the molding machine. AKTIESELSKAPET MOSS GLASVAERK. Norw. 44,612, Nov. 14, 1927.

Conveying the glass from the smelting furnace to the molding machine. AKTIESELSKAPET MOSS GLASVAERK. Norw. 44,075 and 44,076, May 30, 1927. Mech. features.

Apparatus for distributing melted glass mass into molding charges of desired sizes. AKTIESELSKAPET MOSS GLASVAERK. Norw. 44,788, Jan. 23, 1928.

Mold for glass articles. FRANK M. BIGELOW. U. S. 1,683,755, Sept. 11. Structural features.

Hand-operated apparatus for blowing glass articles. SOC. ANON DES PAVILLONS. Brit. 283,870, Jan. 18, 1927. Structural features.

Glass leer of the muffle type with an endless conveyor for carrying articles through it. WILLIAM A. MORTON (to Amsler-Morton Co.). U. S. 1,684,239, Sept. 11.

Apparatus for forming and annealing sheets of glass. HERMAN S. HEICHERT (to Pittsburgh Plate Glass Co.). U. S. 1,683,973, Sept. 11.

Rolling and annealing plate glass. GEORGE E. HOWARD (to Hartford-Empire Co.). U. S. 1,684,030, Sept. 11. Mech. features.

Polishing glass sheets. GEORGE E. HOWARD (to Hartford-Empire Co.). U. S. 1,684,029, Sept. 11. Mech. features.

Porous clay. EMRICK I. LINDMAN (to The Aerocrete Corp. of Can.) Can. 283,231, Sept. 11, 1928. Clay, preferably quarternary clay, is heated at continually increasing temp. first rather quickly to a temp. near the melting pt. (1000 to 1050°), and then cautiously to such a temp. that the material assumes a viscous consistency to facilitate the expansion of the material by the enclosed gases and form a porous product, whereupon the heating is stopped.

Abrasive paper or cloth. RALPH B. MANLEY (to The Carborundum Co.). U. S. 1,683,623, Sept. 11. A backing such as paper or cloth carries aluminous abrasive grains uniformly distributed and individually spaced on its surface so as to avoid grain clusters and to provide uncovered portions of the backing sufficient in size to prevent permanent lodgment in them of material which has been ground away.

Enameling composition. MAHLON E. MANSON (to Rundle Manufacturing Co.). Can. 282,726, Aug. 21, 1928. An enameling compn. contains 68 parts Na silicate contg. 23% soda and 74% silica, 5 parts $Al(OH)_3$, 13 parts borax, 18 parts sodium antimonate, 6 parts cryolite and 8 parts $BaCO_3$.

20—CEMENT AND OTHER BUILDING MATERIALS

J. C. WITT

New cement-burning process. KARL BIEHL. *Pit and Quarry* **16**, No. 12, 72–5 (1928).—See *C. A.* **22**, 3029. E. H.

Progress in making lime and cement and their effect on masonry. J. BOLOMEY. Univ. Lausanne. *Ciment* **33**, 323–8(1928).—An address. F. O. A.

The decree of December 24, 1927, establishing the specifications for hydraulic cements for public work in France. ANON. *Rev. materiaux construction trav. publics* 1928, 312–6. F. O. ANDEREGG

Metallurgical slags and cements. ANON. *Rev. materiaux construction trav. publics* 1928, 250–4.—At Abrebach in the Sarre slag is first made into portland cement having the compn.: CaO 67.3, SiO_2 18.9, Al_2O_3 6.6, Fe_2O_3 2.2 and MgO 2.6%. The clinker is then ground with granulated slag to form metallurgical cements which meet the Parisian specifications for strength. The method of manuf. is described. F. O. A.

Effect of curing on apparent free lime in portland cement. ARTHUR J. POOL. *Rock Products* **31**, No. 19, 70(1928).—Detns. of the amt. of free lime by the Lerch & Bogue method were made on several cements immediately after grinding and after 1, 3 and 7 days' storage in the lab. in cloth sacks. The quantity of free lime generally showed an increase followed by a decrease, indicating that $Ca(OH)_2$ liberated from the cement compds. by atm. moisture may become carbonated rather slowly. RAYMOND WILSON

Iron oxide *vs.* alumina as a fluxing agent in the manufacture of portland cement. ALTON J. BLANK. *Rock Products* **31**, No. 14, 68–9; No. 18, 78–9(1928); cf. *C. A.* **22**, 2450.—B. points out better grindability of clinker, less ring formation in kilns, longer life of kiln linings and other advantages of adding Fe ore or high-Fe slags to raw mix. RAYMOND WILSON

A recording apparatus for determining the setting time of cement. L. LIAUTAUD. *Rev. materiaux construction trav. publics* 1928, 256–9.—See *C. A.* **22**, 2253. F. O. A.

The contraction of cements. J. COCAGNE AND Y. MATRAS. *Ciment* **33**, 232–4 (1928); *Science & industrie* **12**, 89–94.—The best results are secured by using as little water in the mix as possible followed by copious wetting after the cement has reached its set, by applying rather lean mixes and probably by using sharp aggregates. F. O. A.

Action of distilled and river water on tensile strength of cement test briquets. ALTON J. BLANK. *Rock Products* **31**, No. 14, 66–7(1928).—B. finds no retrogression in tensile strength when briquets are stored in distd. water, whereas retrogression is common when a calcareous river water is used for storage. RAYMOND WILSON

The red corpuscles in the blood of cement workers. WALTER SALECK. *Arch. Hyg.* **99**, 60–70(1928).—The effect of continued inhalation of cement dust in the cement

factories is to increase greatly the no. of polychromatic erythrocytes. Some of the workers showed fine basophilic granulated erythrocytes, which did not resemble the corresponding erythrocytes found in the blood of lead workers. The cement workers showed considerable resistance to disease; and the respiratory organs were especially resistant. P. Y. JACKSON

Equation for predicting strength of concrete. F. N. WRAY. *Eng. News-Record* **101**, 291–2(1928).—An equation is given by means of which it is possible to predict the strength of concrete at any age between 7 days and 5 years when the strength at any other age between these limits is known. R. E. THOMPSON

The determination of the compressive strength of mortar and concrete. R. DUTRON. *Rev. materiaux construction trav. publics* **1928**, 215–20, 254–6, 293–7.—Various formulas are tried out. F. O. A.

A new mold, and concrete test methods on Port of New York Authority bridges. A. W. MUNSELL. *Eng. News-Record* **101**, 140(1928).—The concrete control methods employed are described briefly. A new mold having many advantages is also described. R. E. THOMPSON

Beam tests of pavement concrete placed by two methods. THOMAS R. BEEMAN. *Eng. News-Record* **101**, 200–2(1928).—Standard concrete of 1:2:3 mix (1.67 barrels of cement per cu. yd.) was compared with a leaner concrete of 1:2:4$^1/_2$ mix (1.30 barrels of cement per cu. yd.) compacted by vibrating machines. The latter differed from "vibrolithic concrete" inasmuch as crushed rock was not forced into it by the vibrating machines. Tests at 28 days (including 10 days' water curing) showed the former to be 15% stronger under tension at the bottom and 12.1% stronger under tension at the top. The modulus of rupture of the standard pavement was 4.6 and 2.6% greater with tension on the bottom and top, resp. The standard specimens showed uniform structure throughout, while the compacted slabs showed excellent structure and density in the top half but poor structure in the lower half. R. E. THOMPSON

Proportioning concrete mixes for the Coolidge Dam. BRUCE JOHNSTON. *Eng. News-Record* **101**, 66–7(1928).—Brief details are given of the proportioning methods employed during the construction of the Coolidge Dam. A series of tests, the results of which are presented graphically, showed a straight-line relation between the mortar strength and the cement content when the consistency was kept const. The water is not measured directly, but the consistency of the mix is rigidly controlled. Segregating the rock into 3 classes has greatly facilitated control of the mix and made possible very consistent and uniform results. The agreement between the 28-day strength of the mortar and the job concrete is striking, being 2900 and 3150 lb. per sq. in., resp., for class A concrete, and 2450 and 2480 lb. per sq. in., resp., for class B concrete. R. E. THOMPSON

Elastic stresses developed in arch dams by varying conditions of temperature and shrinkage of concrete. HAEGELEN. *Annales pont chaussees* Nov.-Dec., 1927; *Ciment* **33**, 198–202. F. O. A.

Permeability of concrete. W. HUGENTOBLER. *Ber. Kommission Abdichtungen Schweiz. Wasserwirtschaftsverbands* **1928**, No. 5, 96; *Beton Eisen* **27**, 261.—The permeability of concrete varies with the amt. of cement and inversely with the amt. of water. Stone dust, hydraulic lime, etc. have little effect, although up to 9% $Ca(OH)_2$ is beneficial. Natural sand and gravel give better results than crushed rock. When specimens are stored damp the permeability is greater than when stored dry, although the former on drying out approach the latter. The penetration of water is faster at the start of the expt. and depends upon the pressure. Specimens stored 53 and 97 days gave similar results. A pitch coating withstood fairly high pressures, while bituminous coatings were sometimes helpful, sometimes not. Surfaces plastered with cement mortar withstood small pressures but not larger ones. A metal coating sprayed by the Schoop process withstood 15 atm. pressure. F. O. ANDEREGG

Deterioration of concrete by corrosive waters. R. GRÜN. *Chem. Fabr.* **1928**, 281–3, 294–5.—The most important damage is caused by H_2SO_4 either combined in sea water or free in natural acid water. Ordinary concrete can be made resistant by producing a dense non-porous aggregate of uniformly sized material. At least 400 kg. of cement per sq. m. must be used. Painting with bitumen is beneficial and better than covering with clinker and cement. Aluminous cement with 7–50% Al_2O_3 is very resistant to $MgSO_4$, but its behavior in presence of Na_2SO_4 is doubtful. The resistance of pozzuolana to corrosion is very great, as is shown by the existence of water mains in good condition today constructed by the Romans of this material. The effect of its addn. to concrete is to increase the d. and to liberate lime, which acts protectively. It can only be used with slow-setting concrete. Cements prepd. from blast-furnace

slag fall into the same class; or a mixt. of blast-furnace slag and portland-cement clinker may be used. Those made from acid slags have not a high initial strength, but if the clinker content is low they are very resistant to salt water. Aluminous slags have the best "hydraulic" qualities of any, but are not so resistant to corrosion as might be expected. Basic and Mg slags also make good cement, but it is not resistant to salt water. Generally speaking, all these cements have less initial strength than portland cement, but greater resistance to corrosion. B. C. A.

Recent developments in wood preservation. ROBERT NOWOTNY. *Oesterr. Chem.-Ztg.* 31, 126–9(1928).—The *Boucherie process* ($CuSO_4$) is still widely used in Switzerland, France, Holland and Sweden. 1927 statistics of the Swiss Telegraph Department show an av. life of 20.1 years for poles. These poles receive rigid inspection and are treated with a $CuSO_4$ soln. of only 0.8% strength. N. ascribes this long life to the favorable Swiss climatic conditions. In France, the dry treated poles are given a butt-treatment with hot creosote as an addnl. protection. Recent experience with pressure treatment in properly protected cylinders has not been entirely satisfactory. *Kyanizing* ($HgCl_2$).—The older open-vat methods gave a penetration of only a few mm., particularly with fir and hemlock poles. Attempts to obtain deeper penetration by means of pressure in protected cylinders has so far failed. By a preliminary treatment with chem. solns. and steam, Kinberg obtains a penetration of 3 to 4 cm. in fir. In the Dia-Kyanizing process of Hugron, the poles are first heated with steam or dry air and then immersed for 3 to 4 days in the $HgCl_2$ soln., a uniform penetration of 3 to 4 cm. resulting. *Fluorides.*—NaF is rarely used alone, but is the main ingredient of a no. of new preservatives. Basilit, NaF + dinitrophenol + aniline (B. MalenKović 1909), was the prototype of the series which, among others, includes Malenit, Triolith, Fluoran. These are combinations of NaF and nitrated phenols or cresols, with the addn. of small quantities of other salts such as chromates to reduce metal corrosion. The NaF in these combinations penetrates deeply into the wood, is not fixed by the wood fiber and is leachable, whereas the dinitro compds. which do not penetrate so deeply are fixed by the wood fiber and are not easily leached out. They also stain the wood an intense yellow. Falck proposes boring holes in timbers 2 cm. in diam., 30–40 cm. apart longitudinally and 4 cm. laterally, filling with dinitrofluoride salts and closing with wooden plugs. The salts will gradually diffuse into the surrounding wood. The *Cobra* process injects dinitrofluorides into wood in the form of a paste by means of a puncturing hammer. Fluosilicate salts are highly toxic and particularly suitable for interior surface treatments. *Arsenic compounds.*—According to R. Falck, As compds. belong to the most toxic group of preservatives, particularly $NaAsO_2$. The latter should not be used in building interiors on account of possible AsH_3 liberation by molds. Compds. of org. color bases with arsenious acid have promising possibilities. Curtin (cf. *C. A.* 22, 857), after demonstrating that the secretions of certain wood-destroying fungi are acid and are capable of dissolving insol. toxic salts, has developed a new preservative, Zn metaarsenite, highly toxic and not leached out by water. Based on the same principle, Malenković had previously proposed a process that forms Zn_2OF_2 in wood by using $ZnCl_2$ and NaF solns. *Oil impregnation.*—The most important oil preservative is still coal-tar creosote. The empty-cell Rueping process is most generally used. With refractory woods like fir and hemlock, mech. perforation or puncturing is resorted to to obtain more satisfactory penetration. What the most desirable constituents of creosote are is still an open question. In recent years the lower-boiling compds. are considered less desirable than formerly, since wood is now treated with a very small final retention of creosote. After the disappearance of the more volatile oils it is a question whether enough creosote remains to preserve the wood. Falck ascribes a higher effectiveness to the higher-boiling compds. Gram proposes the addn. of low-temp. tars rich in paraffin to creosote to retard evapn. and to waterproof the wood. A. Becker proposes a double Rueping treatment, creosote followed by malenit soln. An extensive bibliography is included. ALFRED L. KAMMERER

Wood preservation in Western Australia. C. R. KENT. *Chem. Eng. Mining Rev.* 20, 341–4(1928).—*Powellizing* is the only preservation process used in Western Australia to any extent and it has been used by the railroads in treatment of karri sleepers since 1909. Later As was added to prevent termite attack. The green timber is run into open vats, covered with a water soln. of 11% molasses and 1% As_2O_3 which is heated to near boiling for 8 hrs. The soln. is then allowed to cool 12 to 16 hrs., after which the timber is removed. *Service records.*—In districts of high rainfall and poor drainage, that is where conditions were favorable to decay, the av. life of Powellized karri sleepers was 8 to 10 years, compared with 15 to 20 years for untreated jarrah, whereas in districts having low annual rainfall and conditions unfavorable to decay but

favorable to termite attack, the Powellized karri sleepers gave excellent service. Between these extremes, intermediate results were obtained. In no instance was failure of Powellized karri due to termite attack. The records demonstrate the value of Powellizing in termite-infested districts possessing climatic conditions unfavorable to decay. In view of the above, J. E. Cummins of the Forest Dept. developed the *Fluorizing* process, employing a water soln. of 3.5% NaF, 0.3% Na dinitrophenate and 1.0% As_2O_3, the latter added as an insecticide against termites. Com. treatment began in 1926. The treating operation is the same as that used in Powellizing described above. Green karri gives better penetration than dry and little is gained by pressure. Culture tests with *Trametes lilacinogilva* grown on potato-dextrose-agar indicated the following concns. necessary to kill the fungus: Powellizing soln. 8.0%, $ZnCl_2$ 0.35%, NaF 0.25%, Na dinitrophenol 0.025%, 90 NaF + 10 Na dinitrophenol 0.06%. A. L. K.

Grozny paraffin mazout and creosote oil as wood preserver. A. Voronov. *Neftyanoye Khozyaistvo* **12**, 550–3(1927).—Sludge formed in mixing paraffin mazout with creosote oil retards the mixt. from entering the wood. The most suitable proportion was established as 1:1. The wood must be dry to obtain a complete impregnation. The amt. of sludge formed can be considerably decreased by using a light fraction of creosote oil (below 350°). A good impregnation increases the wt. of wood by 88%. A. A. Boehtlingk

Treated timber still good after 45 years of exposure. W. B. Gregory. Tulane Univ., New Orleans. *Eng. News-Record* **101**, 355–6(1928).—The results are given of strength tests on creosoted southern pine timbers which had been continuously exposed in a sub-tropical climate with an annual rainfall of more than 56 in. The timbers compared favorably with new untreated wood and with recently treated wood of the same general characteristics. Details are given of the specifications under which the creosote treatment was carried out. R. E. Thompson

The rational utilization of coal-tar oils and pitch [on roads] (Trabuc) **21.** Rotary kiln for manufacture of cement (Brit. pat. 283,669) **1.** Protective coatings for wood or stone (Brit. pat 283,664) **9.**

Cement. Karl Biehl (to Wickingsche Portland-Cement- und Wasserkalkwerke A.-G.). Can. 282,926, Aug. 28, 1928. A hydraulic cement comprises hydraulic lime-alumina silicates, and a mixt. of $NaHSO_4$ (0.6%) and NaCl (0.3%) incorporated therewith.

Acid-proof cement. I. G. Farbenind. A.-G. Brit. 283,471, Jan. 8, 1927. A water glass soln. is mixed with a powder contg. substances such as tungstic acid, salts of fluorozirconic, fluorogermanic, fluoric, fluorotitanic, fluorotantalic, fluoroniobic and fluorostannic acids, Si, Si alloys, fluosilicates, cryolite or Al, having a strong capacity for combining with alkali as measured by the method described in Brit. 256,258 (*C. A.* **21,** 2972). Small quantities of these substances may be admixed with quartz sand for further admixture with water glass. Cf. *C. A.* **22,** 3756.

Cementitious compositions. Jesse A. McCormick and Charles A. Cabell (to National Lime Association). Can. 283,431, Sept. 18, 1928. A cementitious compn. comprises hydrated lime, Ca aluminate, $Al_2(SO_4)_3$, a slightly sol. carbonate, and from 0.1 to 0.3% of sugar. Cf. *C. A.* **22,** 1026.

Composition for pavements. A. Kennedy. Brit. 284,100, March 4, 1927. A mixt. of natural or artificial cement (suitably portland cement), sand and crushed granite, limestone or slag is applied in a dry state to the surface of tar macadam roads before rolling; after rolling addnl. material may be applied, brushed in and treated with water, and the rolling and other treatments may be further repeated.

Building material. Thv. Hansen. Norw. 45,031, April 2, 1928. A mixt. of finely ground peat with a size of particles below 0.2 mm., sawdust, soapstone powder and magnesia cement is molded with or without pressure.

"Acoustic wall" for avoiding reflections of sound inside of buildings. Georg von Arco (to Gesellschaft für Drahtlose Telegraphie m. b. H.). U. S. 1,684.078, Sept. 11.—A coating of flaky sound-absorbing material such as flaky asbestos assocd. with binding material is used for surfacing walls.

Non-inflammable coating composition. Sigurd Jenssen. Norw. 44,529, Oct. 24, 1927. Cement and burned magnesia are mixed with whey with or without an addn. of pigments. The whey may also be applied in evapd. dry condition mixed with the other components.

Impregnating wood. A. Dessemond. Brit. 283,703, Dec. 1, 1926. In processes

involving successive impregnation of wood with different liquids, followed by vacuum treatment, the liquid extd. by the vacuum treatment is measured in order to control the degree or duration of the vacuum and to det. the proportion of the liquids remaining in the wood.

Preserving wood. GILBERT GUNN. U. S. 1,684,222, Sept. 11. Wood is treated with a slightly acid aq. soln. of $K_2Cr_2O_7$ and $CuSO_4$ and their reaction products, contg. more than a mol. proportion of $K_2Cr_2O_7$. Cf. *C. A.* **22**, 1838.

The synthesis of liquid fuels. DANIEL FLORENTIN. Lab. municipal de Paris. *Chimie et industrie* Special No., 228–34(April, 1928); cf. Kling and F., *C. A.* **20**, 1587, 1791; **21**, 2466, 2470, 3197; **22**, 400.—A review dealing briefly with the various processes proposed, and more fully with the Bergius process and the results obtained therewith by Kling and F. A. PAPINEAU-COUTURE

Chemical study of Italian fuels. CARLO PADOVANI. *Chimie et industrie* Special No., 181–7(April, 1928).—An outline of the systematic investigation being carried out on the chem. compn., properties and possible industrial uses of Italian fuels, with a view to utilizing them to the best possible advantage. The results obtained so far have been described in full in a vol. published by the Ass'ne Chim. Gen. ed Appl., Rome, which will be followed by other vols. as subsequent results may warrant. A. PAPINEAU-COUTURE

A study of the determination of moisture in fuels with high oxygen content. CARLO PADOVANI AND CESARE SINIRAMED. *Chimie et industrie* Special No., 177–80(April, 1928).—In order to eliminate the errors due to oxidation, 4 methods of drying were compared: (1) in a Fischer oven through which a current of dry CO_2 was passed (time 3–4 hrs.); (2) in a Langbein app. (placing the sample in a small flask through which dry CO_2 was passed, and heating 2–3 hrs. in an ordinary oven at 100–10°); (3) drying over P_2O_5 at atm. temp. (time required 4–5 days); (4) heating at 60–70° to const. wt. in a vacuum oven at an abs. pressure of 70 mm. of Hg, after displacing the air with CO_2. The 4 methods give practically identical results (av. of 6 detns. by each method varying from 12.09 to 12.21% on the same coal), (1) being the most convenient. Even with this method increases in wt. were observed in the H_2O detn. in some samples of exceptionally moist and exceptionally easily oxidized lignites and peats. Satisfactory results were obtained by substituting N for CO_2, and the current of gas was passed through $CaCl_2$ and through $Ba(OH)_2$ water to absorb the evolved H_2O and CO_2, resp. It was found that the loss in wt. is always greater than the amt. of H_2O absorbed by the $CaCl_2$ and that the difference between the 2 is always greater than the amt. of CO_2 evolved, which is probably due to the evolution of other occluded gases, particularly N. P. and S. consider it more likely that the CO_2 evolved is produced by reaction between the coal and previously absorbed O, rather than that it was absorbed as such from the atm. A. PAPINEAU-COUTURE

Benzene. GEORGES CORET. *Chimie et industrie* Special No., 239–43(April, 1928).—A discussion of the merits of benzene as a fuel for internal-combustion engines. A. PAPINEAU-COUTURE

Advances in the chemistry of the humic acids and of coal. WALTER FUCHS. Kaiser Wilhelm-Inst. für Kohlenforschung. *Z. angew. Chem.* **41**, 851–3(1928). E. H.

The auto-ignition temperature of Diesel oil. TETSURO SUWA. Imperial Fuel Research Inst., Japan. *J. Fuel Soc.* (Japan) **7**, 589–97; (In English 53–6)(1928).—Auto-ignition temp. (hereafter denoted A. I. T.) is influenced by several factors, namely: material, shape and vol. of the crucible, kind of gas used and its quantity passed, vol. of oil drop under test, atm. pressure, and method of heating. The A. I. T.'s of several tar oils used in testing a 33 b.h.p. single-cylinder Diesel engine were detd. with an improved Moore type app., provided with a Pt crucible of 14.8 cc. vol., in an atm. of O flowing at the rate of 15 cc. per min. The diffusion block of semi-steel of 110 mm. diam. and 105 mm. height was heated at the rate of 1–2° per min., and an oil

drop under test was allowed to fall into the crucible every 2-3° temp. rise. The following results were obtained:

No.	Description		A. I. T.
1	Normal heptane		300°
2	Kerosene		256
3	Heavy oil A		256
4	Heavy oil B		263
70	Fushun low-temp. tar, crude		337
71	Fushun pitch-free oil		405
72	Fushun acid-free oil		287
73	Fushun tar acid		501
60	Okinoyama low-temp. tar, crude		430
61	Okinoyama pitch-free oil		418
62	Okinoyama acid-free oil		292
63	Okinoyama tar acid	above	580
50	Saghalien low-temp. tar, crude		409
51	Saghalien pitch- and acid-free oil		275
52	Saghalien paraffin-free oil		393
53	Saghalien tar acid	above	600

Diesel engine fuels should have a low A. I. T., to insure their combustion in the cylinder. The temp. attainable in the cylinder during the compression stroke can be calcd. by means of the formula $T = T_0\delta^{n-1}$, where T and T_0 are, resp., final and initial abs. temps. of suction air, δ is the compression ratio and n approx. 1.35 in the case of the Diesel engine. Diesel-oil specifications should include A. I. T., and the method of its detn. F. I. NAKAMURA

Chemical and economic considerations concerning wood and coal. FRIEDRICH BERGIUS. *Chem.-Ztg.* 52, 447(1928); *Z. angew. Chem.* 41, 707-11.—In studying the transformation of wood into coal, the attempt was made to shorten nature's process by using high temps. and employing H_2O (as superheated steam) to distribute the heat, thus preventing decompn. by the exothermic reactions involved. Both cellulose and wood gave practically the same coal as end products; apparently it is immaterial whether cellulose or lignin is used. By employing mechanical pressure (up to 6000 kg./sq. cm.) to imitate the great forces occurring in nature when anthracite was formed, a coal contg. 87% C was produced, and CH_4, H_2, CO and CO_2 were evolved simultaneously. The H of coal has a certain "lability" at 350° so that an enriching of the coal in H can be had by heating it with H under pressure. The practical question of dehydrating peat led to the study of coal formation, and the commercial importance of obtaining hydrogenated products from coal was stimulated by the world-wide demand for oil. In utilizing wood chemically so that digestible carbohydrates may be made from it, the cellulose skeleton must be retained. Energy in the carbohydrates is utilized very efficiently by animal organisms both for fuel and for tissue building. How much better it would be for firewood to be used for food rather than for fuel, especially when coal can be had so cheaply. The conversion of cellulose into digestible carbohydrates is based upon hydrolysis with concd. HCl, and later removal of the reagent, without decompg. the carbohydrate formed. Far-reaching technical, economic, transportation and other problems must be studied before the process can be employed commercially. For Germany this matter is especially important as 60% of its meat supply comes from hogs grown within the country itself. W. C. EBAUGH

The origin of coal. WALTER OBST. *Chem.-Ztg.* 52, 629(1928).—A lecture by Bergius (preceding abstract) reminded O. of an accident to a sack of corn meal which became wet and was placed above an oven to dry. After 4-5 weeks the meal was found to be dry and unchanged, except for slight dextrinization near the bottom, but the bottom of the sack had portions of coal up to 10 cm. in length. The temp. was detd. to be 70-90° at the place in question, and the pressure could not have exceeded 50 kg., the total weight of the filled sack. It points to the possibility of coal originating at low temp. and pressure from carbohydrates admixed with certain oils. W. C. E.

Washing of coal by flotation: effect of alkali chlorides contained in the water on the stability of the foam. M. E. BERTHET. *Chimie et industrie* Special No., 217 (April, 1928).—The stability of the foam decreased very rapidly with increase of NaCl up to about 3 g. per l. of H_2O; at higher NaCl concns. the rate of decrease in stability with increase in NaCl was much lower. The stability is not increased by increasing the time of agitation. A. PAPINEAU-COUTURE

Two laboratory investigations on the dissociation of coal. I. Laboratory appara-

tus for studying the low-temperature carbonization of coal. A. GILLET AND M. RORIVE. *Chimie et industrie* Special No., 163–4(April, 1928).—In the lab. app. used for investigating low-temp. carbonization, there is a gap between Fischer's small still (taking about 50 g. coal) and his large rotary still (taking a few kg. of coal), which G. and R. have filled by designing an app. which can handle about 400 g. in 1 hr. It consists essentially in an inverted funnel heated on a molten metal bath (as in the Piron-Caracristi process used commercially in the Ford plant for the treatment of 4000 tons per day). The upward-projecting stem of the funnel is connected to the usual condenser and is provided with a tube for introducing steam or a suitable gas and for a thermo-elec. couple for detg. the temp. Preliminary tests with a Ruhr coal with 28% volatile matter confirmed the results obtained by Audibert, Ste.-Claire-Deville, and others on the coking of coal, bringing out particularly the effects of the size of the coal grains, of the rate of heating and of the addn. of a few % of infusible powders (particularly of semi-coke) on the properties of the semi-coke. **II. Extraction of coal with cyclohexanol at 360°.** A. GILLET AND H. DETAILLE. *Ibid* 164–5.—Treatment of coal contg. 28% volatile matter with cyclohexanol at 360° in presence of a catalyzer (a mixt. of reduced Fe and Sn) gave 44% of combined extract and volatile matter, which was increased to 54% on treating with a 2:1 cyclohexanol-PhOH mixt. The ext. was non-volatile at atm. pressure and contained at least 50% cyclohexanol, which was combined in an unknown manner. The cyclohexanol-PhOH ext. was sol. in concd. H_2SO_4; only traces of this ext. were sol. in concd. NaOH soln., giving on acidification traces of products having a sharp, cresol-like odor. A. PAPINEAU-COUTURE

The chemical utilization of coal. CH. BERTHELOT. *Chimie et industrie* Special No., 166–76(April, 1928); *Science et industrie* 12, 90–3; cf. *C. A.* 22, 152.—An address dealing with carbonization and liquefaction of coal and with the utilization of the products of gasification of coal. A. PAPINEAU-COUTURE

The chemical composition of the hydrocarbons in coal and its effect upon the coking of coal. HUGO NOVÁK AND J. HUBÁČEK. *Paliva a Topeni* 9, 165–70, 187–96(1927).—The authors summarize and review 14 papers published since 1923 and commence by dissolving coal in tetrahydronaphthol at 18 atm. and 300°. Brown coals "Karolina" and "Hedvika" and black coals "Max" and "Jaroslav"—all from Czechoslovakia—were used. The above treatment seps. the coal into 2 fractions—one contg. most of the hydrocarbons and a residue. By treating these fractions with solvents as benzene, petr. ether, EtOH, pyridine, and NaOH, groups were formed with similar and characteristic properties. For greater precision the large groups were sepd. from small groups representing a small percentage of the hydrocarbons but which form a transition from one large group to another. FRANK MARESH

Results of agglomeration of coals by means of hydrocarbons partially dehydrogenated by sulfur. ANDRÉ LÉAUTÉ. *Compt. rend.* 187, 227–9(1928); cf. *C. A.* 22, 3761.—Actual tests on coals agglomerated with different heavy oils show that the partial dehydrogenation of the oils by means of S increases very markedly the strength of the briquets. G. CALINGAERT

The determination of sulfur in coal with the aid of a turbidimeter. B. TYKAČ AND JINDŘICH STREIT. *Paliva a Topeni* 9, 133–5(1927).—One g. of coal is burned in the usual way in a calorimeter bomb. The bomb is washed thoroughly into a beaker and filtered. The soln. is titrated with 0.1 *N* Na_2CO_3 against methyl orange and boiled to remove all traces of CO_2. From the acidity (1 cc. *N* Na_2CO_3 corresponds to 16.035 mg. S) a rough estn. is made, and a vol. corresponding to the range of the instrument is pipetted out, treated with 1 cc. HCl (1:1), and made up to 100 cc. In the turbidimeter, a $BaCl_2$ capsule is added to the soln., and the depth of the soln. at which the flame disappears is read. From the formula $S = 0.6 + 15.3/c$, where c is the depth in cm., the mg. of sulfur (S) are computed. From numerous tables, the agreement of the total S in coal with gravimetric and the Eschka method is very close (less than 0.06% difference). (A complete résumé is given in German.) FRANK MARESH

The sulfur problem in burning coal. J. F. BARKLEY. Bur. Mines, *Tech. Paper* No. 436, 7 pp.(1928).—Furnace reactions in burning coal are discussed and the effect of S content on clinkering is indicated. Clinkering of the ash does not vary directly with the S content of the coal. Often less than 10% of the S goes into the ash, and much goes off as SO_2 or SO_3. As the flue gas temp. drops SO_3 gas begins to unite with water vapor, which on condensation first appears as acid of 98.3% concn., which absorbs water upon cooling. A curve shows the dew-point temps. for the different partial pressures of the acid. W. H. BOYNTON

Hydrogenation of Japanese coals. YOSHIKIYO OSHIMA AND SABURO TASHIRO. The Imperial Fuel Research Institute, Japan. *J. Fuel Soc.* (Japan) 7, 637–42; (In

English 70-2) (1928).—This is the first report on hydrogenation of Japanese coals. The following 3 points were considered: conditions governing the nature of the oil produced, easy sepn. of oil from the residue, and factors necessary for industrial application. The app. used was an autoclave of Ni-Cr steel heated externally by an elec. heater. The sample of coal and H, at a definite pressure, was charged into the autoclave, and the latter was heated at a definite rate and shaken horizontally. The pressure and the temp. were observed every 2 min. The relations between temp. and pressure, pressure and time, and time and temp. were illustrated by 3 curves, and the results are fully discussed. The following results were obtained with certain Japanese coals:

A Analysis of Coal

Sample	Volatile matter	Fixed C	Ash
A	45.38	37.62	17.00
B	41.44	45.78	12.78
C	37.32	52.54	10.24
D	40.98	50.96	8.06
E	42.34	38.86	17.80
F	54.12	29.30	16.58

B Results

Sample	Light Hydrocarbons	Heavy Hydrocarbons	Total Oil Yield	H consumption
A	8.4	76.1	84.5	4.8
B	8.0	70.8	78.5	5.4
C	6.7	60.8	67.5	5.5
D	3.3	75.6	78.9	6.2
E-1	6.1	90.3	96.4	5.0
E-2	15.8	79.4	95.2	4.8

(Figures are based on pure coal.) The detailed report on further investigation will be published in the future. F. I. Nakamura

Influence of varying the pressure and duration of heating upon the results of low temperature distillation of coal. R. Vondráček and B. Hlavica. *Paliva a Topeni* 9, 49-56, 69-74, 85-9, 101-5(1927).—Lignite from Handlová (Slovakia) and coal from Moravian Ostrava were distd. at atm. pressure and in a vacuum The duration of heating varied from 7 to 1000 hrs. The usual methods of analysis were used or improved in some detail for the expts. attempted. The results of the distn. of both coals were compared with each other and with those of other experimenters. The authors question some results obtained by Börnstein to the effect that coals poorest in O should yield the most CO_2. An apparent evolution of H from lignite begins at 400°, while coal evolves H at a lower temp. CH_4 is evolved at the same temp. in both coals. The yields of CH_4 and H are about the same. Brown coal, in fractions below 300°, gives more CO_2 and less of the higher homologs of CH_4. The semi-cokes from both types of coals attain the same compn. at 620°. With a slow rate of heating, the compn. changes in the range of low temps. with a larger yield of gases, primarily CH_4, than rapid heating. The calorific value of gases from lignite was increased 30% by slow heating up to 520°, but 38% for coking coal. Since the gases contain only about 10% of the calorific value of the coal, the effect of slow heating is almost negligible. The yield of tar was increased but slightly under slow heating, but the content of phenols and asphalt was decreased. Distn. *in vacuo* has no fundamental influence upon the compn. of the carbonaceous matter of coal. Through secondary reactions in the gaseous phase, the compn. is altered with an increase of H. The wt. of evolved gases is not changed. Under rapid heating in a vacuum, the calorific value of the gases is lowered, but under slow heating in a vacuum, the calorific value of the gases is increased. Distn. *in vacuo* has an unfavorable influence upon tar formation; the content of free C, phenols and asphalt is increased. An unexplained observation was noted, that in the dry distn. of lignite in a vacuum, the content of N and S in the semi-coke was lowered very markedly. This was scarcely noticeable in the coking coal. Low-temp. distn. in a vacuum will hardly have any practical use. A greater significance can be attached to the rate of heating. Elementary N was liberated from both coals below 500°. Brown coal acquired electroconductivity at a slow rate of distn., *in vacuo* at 570°, while F. Fischer's observations showed that under normal conditions of distn. a temp. of 700° is required. (The article is given in French, and only the résumé is in Czech.) Frank Maresh

Pressure extraction of bituminous coal with tetralin under pressure. E. BERL AND H. SCHILDWÄCHTER. *Brennstoff-Chem.* **9**, 105–13(1928).—A gas coal and a semi-bituminous coal were extd. with tetralin under 6.5 atm. and at 250°. The yields of extractable matter on exhaustive extn. were 20.3 and 16.6%, resp. By distn. of the extd. residue at low temps. little tar was recovered showing that extn. with tetralin removed most of the tar-forming constituents. The tetralin extract contd. 1.43% acid compd. (solid phenols), 0.034% bases, 7.84% asphalt and resinous compd., and 27.1% neutral oils. The neutral oils were sepd. into unsaturated (79%) and saturated (13.8%) compds. From the former, 11 different hydrocarbons were isolated, $C_{12}H_{20}$ to $C_{28}H_{34}$ having formulas C_nH_{2n-4} to C_nH_{2n-18}. The saturated compds. were waxes of the formula C_nH_{2n+2}. Petroleum-ether-insol. asphalts were shown to possess aromatic structure.
J. D. DAVIS

Carbonization in vertical retorts. JAMES L. HYSLOP. Belfast Corp. Gas Works. *Gas J.* **183**, 447–9(1928).—Carbonization has now reached a higher efficiency in continous vertical retorts than in any other form. Eighty-five % of the potential heat in coal is returned in one form or another to the consumer. The process has great flexibility adapting it readily to any class of coal and permitting a control of products to meet market conditions, in conjunction with steaming to which it is well adapted. The extra coke consumed in steaming to produce a certain addnl. no. of therms of gas was found to be 40% of that required by a blue water-gas plant. Twenty to twenty-five % of the coke produced is used in heating the retorts. The absence of clinker formation permits long operation without interruption for cleaning. The quality of gas is seriously reduced for several hrs. after cleaning. Data are given showing that this can be largely eliminated by cleaning out one-half of the grate at a time. Because of the low temp. of the coke discharged and other features, 35–40% of the potential heat in the coke consumed may be utilized in the generation of steam. This is about twice the amt. available with horizontals. By using a high-velocity induced-draft fire-tube boiler, sufficient steam may be produced by this waste heat to meet all of the requirements of the plant. Steady pressure at the gas off-take, as near to atm. as possible, is necessary for the maintenance of yields and quality of products and the working of the plant, especially the avoidance of pipe stoppage due to the hard dry condition of the tar caused by fluctuating pressure or heavy vacuum. This control is secured by foul gas mains of ample size and a sensitive governor as close to the collecting mains as possible. Well screened, nut-size coal gives the best results with steaming. The presence of fines is detrimental because of obstruction of the flow of gases through the charge. In connection with high thermal yields of gas from certain classes of coal, it is shown, in a specific instance, that, although the coke yield remained about the same, the increase in gas-therm yield per ton of coal, by using a higher quality coal, was more than offset by the decrease in tar and NH_3 yields, so that the cost per therm of gas was actually greater.
F. S. GRANGER

Carbonization of anthracite and semi-anthracite fines for the production of hydrogen to be used in the synthesis of ammonia. J. DEMAY. *Chimie et industrie* Special No., 188–201(April, 1928).—Lebeau has shown (*C. A.* **17**, 3411; **18**, 3107; **19**, 3010) that carbonization of low-volatile coal gives a gas very high in H (up to 80% and over). D. suggests the carbonization of such fines for the production of H. The use of the types of oven at present in use for the manuf. of coke or of coal gas has been found unsuitable for the purpose; but lab., semi-com. and com. scale expts. have shown that such a carbonization could successfully be carried out with a good yield of gas contg. 50% H and over by inserting a perforated tube into the mass of coal to ext. the gas. As such grades of coal are infusible and non-coking, continuous feeding and withdrawal of the coal could easily be carried out. The relatively small quantity of CO (up to about 15%) present in the gas could be eliminated by synthesis of MeOH, as in the Claude process for the purification of H from coke-oven gases. The advantages of the proposed process are briefly discussed.
A. PAPINEAU-COUTURE

Low-temperature carbonization of Australian lignite. DAVID BROWNLIE. *Ind. Chemist* **4**, 284–6, 290(1928)—The enormous deposits of lignite in Victoria occur principally in 3 main areas, Latrobe Valley, Port Albert and Altona. The Marwell lignite from Latrobe Valley has about 40% moisture and 7400 B. t. u. per lb. On drying the prox. anal. is Fixed C 41.5%, volatile matter 55.5, ash 3.0. The exptl. work was carried out, in a plant of semi-com. size, in a cast-iron vertical retort, mechanically continuous in operation and externally heated, of "considerable" height, tapering to a larger diam. at the bottom. Producer gas + air was introduced at the top of the setting and travelled downwards, while the gases and vapors from the lignite passed off at the top in the usual way. Some internal heating could also be provided by passing

products of combustion or the residual gas from the process, heated to any desired temp. in 8 nichrome vertical tubes, upwards through the charge. The raw, wet lignite being almost impossible to carbonize, briquets (small circular tablets 2.5" diam. × 1.75" thick) were used. Three methods of carbonization were tried: (1) low temp. 650° with simple external heating; (2) ditto + a very small quantity of internal heating; (3) ditto + more internal heating by heating the gas to be introduced at the bottom of the charge to 540°. The results of a no. of runs are tabulated. The briquets used had 12–13.75% moisture and a B. t. u. per lb. of 8770 to 9030. The carbonized briquets were excellent, having a B. t. u. per lb. of 13,750, less than 4% ash, 4.5 to 11% volatile matter. They were free burning and absolutely smokeless. They were, however, somewhat friable and hygroscopic. E. G. R. Ardagh

Combustion with oxygen-enriched air. W. Gumz. *Feuerungstech.* **16**, 73–6; 88–90(1928).—G. illustrates the effect of O enrichment by computing the case of a fire-tube boiler. Given proper equipment and cheap O, enrichment is entirely practical, especially for peak loads. Ernest W. Thiele

Manifestations of combustion efficiency. R. Saxon. *Chem. News* **137**, 98–9 (1928).—An app. is described to show the presence of unburned hydrocarbons and soot in the exhaust of internal-combustion engines: part of the exhaust gas is lead through a Venturi tube, drawing in a certain amt. of air. The mixt. is passed over a Pt catalyst, which will glow in the presence of hydrocarbons, and then over a mass of an oxidizing salt, which will glow in the presence of soot. The suggestion is made to increase the efficiency of the engine by replacing the muffler by a turbine, independently driven and used to increase the rate of removal of the exhaust gases. G. C.

The liquefaction of Bohemian wax coal with hydrogen under pressure. Hugo Novák and J. Hubáček. *Paliva a Topeni* **9**, 145–58(1927).—Bohemian wax coal (Corona) from Karlovy Vary (Karlsbad) has been subjected to the action of H at a pressure of 200 atm. and a temp. of 400–450°. The expts. were carried out with 600 g. of coal in a rotating autoclave of 5 l. capacity. Heating at the above conditions for 2 hrs. transformed 50% of the dry coal into liquid oils. Catalysts Sn, Cd, Bi, $ZnCl_2$, Fe_2O_3 and mixts. of Sn with $NiCl_2$, $ZnCl_2$ and NiO were tried. The $ZnCl_2$ acts as a neg. catalyst, while Sn, Cd, Bi, etc., have little or no influence upon the rate of reaction or degree of liquefaction. The yield of tar was one-half of the liquid products, and the chem. compn. of the products was changed by hydrogenating. More than 50% of the liquid product distd. over below 250°. The tar contains about 4% gasoline and solar oil. The gasoline and illuminating oils from liquified coal are equal in quality to those obtained from crude oils so that the refining, especially of benzene, will offer no difficulties. The higher boiling oils contain about $^1/_3$ gas oil and 60% paraffin which corresponds to the compn. of tars from the wax coals. From the fractions boiling above 300°, paraffin wax, gas oil, heavy paraffin oils and other products (phenols, creosotes, etc.), corresponding to destructive distn. products of wax coal tar are formed. (A complete résumé is given in English.) Frank Maresh

Effect of moisture content of coal and coke on oven capacities. Erich Dubois. *Gas u. Wasserfach* **71**, 795–8(1928).—The influence of high water content of coal on oven capacity is analyzed and illustrations and tables are given. Increase of moisture causes a rapid decrease in oven capacity. High moisture content of coke is especially detrimental in self-contained gas producers, and should be limited to 10%. R. W. Ryan

How does coal burn? v. Jüptner. *Feuerungstech.* **16**, 157–61, 172–5(1928).—The greater heat produced when C burns to CO_2 makes it likely, though not certain, that this is the primary reaction of C and O_2, rather than combustion to CO. It is also more probable that a mol. of O_2 will strike the C surface so as to produce CO_2 rather than CO. The expts. of other authors are discussed, but no conclusion is reached. Ernest W. Thiele

The Ruths steam accumulator. R. A. Langworthy. *J. Western Soc. Eng.* **32**, Tech. Papers, 373–88(1927).—The theory and applications of the steam accumulator are discussed. The device acts like a storage battery, storing up steam at times of light demand and releasing it to carry the peak loads. D. Gordon

The Benson process for producing high-pressure steam. H. Gleichmann. *Z. Ver. deut. Ing.* **72**, 1037–46(1928); cf. *C. A.* **22**, 3032.—The principles of the process and structural details of the Benson boiler are discussed. Sketches are shown of exptl. boilers; these can generate 3 to 3.5 tons of steam at 230 atm. abs. Feed-water problems and the design of plants are described. D. Gordon

The heat input of irradiated boiler heating surfaces. O. Seibert. *Arch. Wärme-*

wirt. **9**, 180–8(1928).—An elaborate calcn., for a specified boiler, of the radiant heat input at various points on the tubes. ERNEST W. THIELE

High pressure boiler with indirect heating of the Schmidt Heiszdampf-Gesellschaft. BRUNO SCHAPIRA. *Feuerungstech.* **16**, 196–8(1928).—In this system, the plant steam is generated by means of steam at still higher pressure; this steam is in coils, and travels by natural circulation in a closed system between furnace and boiler. Thus any sort of feed water may be used, and no joints or large masses of water are exposed to the fire. ERNEST W. THIELE

Heat transfer by radiation in gas-filled spaces. WILHELM GUMZ. *Feuerungstech.* **16**, 181–5(1928).—Calcns. are given, based on the latest expts. on the absorption and emission of radiation by CO_2 and H_2O, which show that where these gases are present the radiation as calcd. by the usual methods must be reduced by a factor depending on the compn., thickness, and temp. of the gases. It follows that the side walls of a furnace are more severely heated than has been supposed, and that the kindling arch often used with low-grade fuels is undesirable. ERNEST W. THIELE

Protection of soot blowers against the effect of high temperatures in the furnace. HARRAEUS. *Feuerungstech.* **16**, 61–3(1928).—H. gives brief descriptions of about 12 means of protecting blowers when not in use. ERNEST W. THIELE

The question of materials for furnace and boiler plants. WINTERMEYER. *Feuerungstech.* **16**, 169–72(1928).—A condensed discussion of the choice and treatment of materials for boilers and grates. ERNEST W. THIELE

Possibilities in the development of supplementary powdered coal burners. W. GUMZ. *Feuerungstech.* **16**, 41–3(1928).—Calcn. shows that fine grinding greatly increases the capacity of supplementary powd. coal installations; the coarse particles do not burn on the grate, as was formerly supposed. Advantage should be taken of the properties of powd. coal by increasing the radiant heat absorption and by preheating the air. ERNEST W. THIELE

Top-fired annealing furnaces. OLIVER P. LUETSCHER. *Iron Age* **122**, 211–2 (1928)—Raw producer gas is brought from a mech. producer by steel plate flues lined with insulating brick. L. describes a new method of applying the gas. The system can be applied to existing furnaces with little change. It is equally applicable to both intermittent and direct-fired tunnel kiln types of furnaces as well as to other fuels such as powd. coals or liquids in combinatoin with gas. H. C. PARISH

The Magdeburg gas works. W. SCHWEDER. *Gas u. Wasserfach* **71**, 769–73 (1928).—Original plans and improvements to the Magdeburg gas works are given as well as some technical details of operation. R. W. RYAN

Gaseous carbonization products. P. LEBEAU. Faculté de Pharmacie, Paris. *Chimie et industrie* Special No., 73–90(April, 1928).—The carbonization of various sugars, starches, cellulose, lignins, peat, lignites, bituminous coal and anthracite was studied in the lab. by heating 1 g. in an elec. furnace, the temp. of which was increased by steps of 100° which were each maintained const. for 1 hr. All of the gases evolved at each temp. were exhausted by means of a Hg pump, the condensable vapors being liquefied in a condenser immersed in CO_2 snow at —80°. The total vol. and compn. of the gases given off at each temp. were detd. and plotted against temp. Results which have already been published (*C. A.* **17**, 3411; **18**, 3107; **19**, 3010) are conveniently assembled and discussed, and a tentative classification of fuels according to their gaseous carbonization products is given. A. PAPINEAU-COUTURE

Gas analysis. A simple and accurate apparatus. ANON. *Gas World* **89**, 170 (1928).—The app. was designed by L. Silver, of the Kensal Green gas works of the Gas Light & Coke Co., for complete gas anal., including the detn. of H_2 and CH_4 by explosion of the whole of the residual gas from the absorptions. The large vol. of O_2 required is measured with the help of an auxiliary 100 cc. pipet located beside the usual 50 cc. gas buret and a stationary levelling tube. The 3 are connected at the bottom, by tubing and cocks, with each other and with a Hg levelling bottle. Hg is used, instead of water, for displacement, etc., throughout the app. The measuring vessels connect at the top with the capillary manifold from which are suspended an absorption and an explosion pipet, joined at the bottom, through a T connection, to a second Hg levelling bottle. At the top of the absorption pipet is a 3-way Greiner cock with one lead to the manifold and the other outside and bent downward for drawing in or expelling the various absorbing reagents or gas samples. The manifold is also provided with an outlet closed by a cock. After the absorptions, the auxiliary pipet is filled to the 100 cc. mark with O_2 and its bottom connection is closed. The buret is then nearly filled with O_2 and placed, by means of a 3-way cock at its junction with the manifold, in communi-

cation above with the auxiliary pipet so that the total vol. is read together. The further procedure is obvious. F. S. GRANGER

Desulfurizing gases. BRUNO WAESER. *Chem.-Ztg.* **52**, 617–8, 638–40, 658–9 (1928).—The importance of removing S from gases met in industry can scarcely be over-estd. The washing processes of Burkheiser (1907), Feld (1907–9) and others similar to theirs have not been very successful. Purifying boxes, with mechanical improvements, have maintained their superiority. Even coke ovens must purify their gas if it is to be used in cities. The use of alk. absorbents was more important before activated C took its place as a purifying agent. Dil. solns. of Na_2CO_3, NH_4OH, etc., with or without suspended Fe oxides, first absorbed H_2S from the gases, and later regeneration is effected by blowing air through the mass, thus pptg. S itself (cf. Seaboard-Koppers processes). The financial success depends upon whether there is at hand a market for the S, thiosulfates, thiocyanates, cyanides, etc., formed. The process removes 85–90% of the S and uses 1 kg. Na_2CO_3 for 8 kg. of H_2S. Specially activated Fe and Ni oxides yield superior results. American plants using petroleum as crude material yield gas rich in S but low in CN derivs. The operation of certain California gas plants is cited to show how the use of alk. absorbents with oxides of Fe or Ni, and the admixt. of air, is carried out. Late exhaustive tests of the Burkheiser and Feld (modified) processes have shown them to be unsuccessful from an economic standpoint Gluud and Schönfelder use aq. suspensions of Fe oxides, and others propose that Cu, Ni and Mn compds. be employed. ZnO, CuO, WO_3, MoO_3, Fe_2O_3, oxides of the alkalies, alk. earths and the earths themselves have been used. Proposals to use $Ca(OH)_2$, NH_3 solns., alkali hydroxides or carbonates, etc., come repeatedly in patent literature; similarly processes based upon the reaction of H_2S and SO_2 come up occasionally. The use of activated C goes back to 1879 (Lugo). Various forms of C are now employed; with an excess of air admitted to the gas and then the mixt. led over activated C good results have been attained. As much as 100% S in excess of its own weight can be liberated. Very full references to German, French, British and American patents are given. W. C. EBAUGH

The influence of inert gases and water gas on the rate of flame propagation in technical gases. K. BUNTE AND A. STEDING. Gas Institut. *Gas u. Wasserfach* **71**, 773–8(1928); cf. *C. A.* **22**, 3977.—Measurements were made of the rate of flame propagation for mixts. of varying percentages of air with coal gas, and mixts. of coal gas with 16.7% N_2, 16.7% CO_2, 16.7% flue gas and 33.5% water gas, resp., as well as Karlsruhe city gas. Curves are given for the variation of the rate of flame propagation with percentage gas in the gas-air mixt. CO_2 decreased the rate of flame propagation to a much greater extent than N_2, while water gas increased the rate of flame propagation markedly (from about 42 to 79 cm. per second for gas air mixt. contg. 22% gas). The influence of flue gases in lowering the rate of flame propagation was roughly proportional to the CO_2 content. The addn. of 4.7 and 9.1% methane reduced the rate of flame propagation slightly. These differences in rate of flame propagation are important from the gas users viewpoint as the height of the inner cone of the flame is greater with N_2 addns. than with water gas addns. and this difference increases rapidly with decreasing B. t. u. of the gas. A larger flame gives a lower concn. of heat. Curves are given for flame heights. R. W. RYAN

Natural gas as a raw material for chemical manufacture. R. T. ELWORTHY. *Ind. Chemist* **4**, 275–8(1928).—The present uses of natural gas are listed and the processes for making various products (carbon black, chlorinated constituents, ethylene glycol, H, He, etc.) are briefly described. Much information on the natural gas situation in Alberta, Canada, is given. E. G. R. ARDAGH

Development problems in the exploitation of natural gas. S. J. M. AULD. *J. Inst. Petroleum Tech.* **14**, 190–218(1928).—Persian gas contg. over 10% by vol. of H_2S is sepd. from the oil by a high-pressure vertical or preferably horizontal separator at pressures varying from 60 to 100 lb./sq. in. Different formulas relating pressure drop to gas flow are discussed critically. A thin plate orifice meter connected to a recording instrument in which the differential pressure is measured directly by means of an inverted bell balanced in liquid is found accurate, for low-pressure gas, to less than 2% over a flowing range of 60,000–300,000 cu. ft./hr. The boiler of a hot-water supply app. heated by the complete combustion of gas contg. 6–10% by vol. of H_2S showed no signs of pitting or corrosion and practically no scale after 2 yrs. continuous use. Gas contg. H_2S cannot be stripped by active charcoal because its adsorptive efficiency falls after 10 days' use to about 50% because of the deposition of elementary S in the pores of the charcoal from oxidation of H_2S by traces of air admitted with the gas or the steam. The factors affecting the efficiency of the oil absorption process are the

temps. of the gas and oil, the pressure, the gas/oil ratio, the mech. design of the absorber and the nature of the absorbent. Gasoline engines used on drilling rigs have operated satisfactorily on natural gas contg. "several" percent of H_2S without trouble from corrosion or undue wear. STEPHEN LACEY. *Ibid* 218–21.—A written discussion on the flow of gas in pipes. Curves are given showing the coeff. of friction of a fluid in "smooth-drawn brass" and uncorroded cast-Fe pipes of circular cross-section.

R. E. SCHAAD

Retort construction and the constitution of low-temperature gas benzine. YOSHISADA BAN. Imperial Fuel Research Inst. *J. Fuel Soc.* (Japan) 7, 615–24; (in English 62–7)(1928).—A review of work of several investigators on the compn. of low-temp. light oils. The low-temp. plant at which B. made his investigation consists of 6 cast iron vertical retorts, the total capacity of which is 6 tons per day. The retort is 11 ft. high and slightly tapered; its section is 5" × 2'6" at the center. The retort is covered with carborundum brick to avoid local over-heating, and is heated in horizontal flues, which run backward and forward up to the chimney. The results are illustrated with curves and are discussed in detail.

F. I. NAKAMURA

Carbon as an economical substitute for gasoline in explosion motors. CHARLES ROUX. *Chimie et industrie* Special No., 218–27(April, 1928); cf. *C. A.* 22, 3757.—Peat contg 90% H_2O can be economically treated by mech. means on a com scale to give a granulated product at 75% H_2O content, which can easily be reduced to 50% by air-drying and then to 25% in a dryer using waste heat from a carbonization plant (the details of the process are being kept secret for the time being). Farm tractors equipped with gas producers when operated with carbonized granulated peat ("granol") showed little or no loss of power as compared with the same motor run with gasoline; while with wood charcoal there was a loss of 25–30% power but the motor otherwise ran quite successfully. R. gives a very detailed description of his experience during a 15,000-km. run in a Ford-Montier racing car equipped with a C. G. B. gas-producer, which was fed with "granol" for about 1000 km. and with ordinary charcoal (as used for household purposes) for most of the time. Conclusion: With the present stage reached in the development of gas producers for automotive engines, granol is practically equiv. to gasoline as regards the power developed in the engine and is as reliable and easy to handle; wood charcoal has the only disadvantage of a loss of 25–30% power, which, in new engines, can be compensated by increasing the bore of the cylinders and the compression Raw wood possesses certain disadvantages; it is better suited for stationary producers, but could be used (*e. g.*, in the colonies) with a considerable measure of success for automotive engines.

A. PAPINEAU-COUTURE

Ammonium sulfate: present processes of obtaining it in gas and coke plants. CH. ARNU. *Science et industrie* 12, No. 170, 42–7(1928).

E. H.

The cycle process for ammonia recovery from coke-oven gases. V. I. DENISOV. *J. Chem. Ind.* (Moscow) 5, 13–8(1928).—In the cycle process (cf. Fokin, *C. A.* 21, 3730) coke-oven gases are washed by water trickling in the scrubbers which dissolves both free NH_3 and NH_4 salts. The weak crude NH_3 water above the coal tar is steamed for the recovery of free NH_3 which distils together with some water and forms concd. NH_4OH. Fixed NH_3 together with some unrecovered free NH_3 remains in the stock water; the latter is used, instead of pure water, for spraying the scrubbers in distg. the next batch of coal, and the new crude NH_3 water and stock water obtained are used in the same way. There is always an excess of stock water over the amt. required for spraying the scrubbers and wetting the coal, and this excess must be dumped in the fields, involving thereby a loss of the dissolved NH_3. Another loss of NH_3 is due to the circumstance that fixed NH_3 does not distil and therefore is not recovered. In the old process combined NH_3 was recovered by distn. of the crude NH_3 water with lime. D.'s calcns. show that the treatment of stock water with lime does not pay; the expense of lime, part of which is due to neutralization of free CO_2 and H_2S contained in the stock water, and the expense of steam, are not justified by the value of NH_3 which could be obtained by this treatment after removing the free NH_3 by steam alone. In spite of involving a decrease of NH_3 yield, the cycle process produces NH_4OH at a lower cost than the old process of recovery of NH_3, which was based on the use of lime water. In the 2 yrs. which elapsed since the introduction of the cycle process in Russian coke ovens it was found that the corrosion of Fe parts of the app. by NH_3 water, which was originally feared, did not take place. In an editorial note appended to this paper, D. is flatly contradicted, and a calcn. is given which tends to show that by the treatment of crude NH_3 water and of stock water by lime NH_3 can be obtained at a lower cost than by the cycle process.

BERNARD NELSON

The cycle ammonia process. M. D. LIPYATSKIKH. *J. Chem. Ind.* (Moscow) 5,

480-3(1928); cf. Fokin, *C. A.* **21**, 3730 and Denisov, preceding abstract.—Compared with the old process the cycle process gives a lower yield of NH_3. Thus by the lime water method recovered NH_3 represented 0.22% of the wt. of the dry coal used; by the cycle process the yield of NH_3 is 0.13-0.22% of the wt. of coal. The yield of NH_3 obtained by the cycle process could be greatly improved if volatile NH_3 were entirely removed from the crude NH_3 water in the distn. column; unfortunately existent app. do not lend themselves to a complete sepn. of volatile NH_3. To recover the volatile NH_3 the crude NH_3 water is treated with a direct current of steam and, as some of the latter condenses thereby, the residual soln. of fixed NH_3 (stock water) is unduly dild. and is obtained in too large a vol. to be completely used for spraying the scrubbers and for wetting the coal. Part of this water is thrown away and involves a corresponding loss of the fixed NH_3 it contains in dil. soln. This loss could be avoided by distg. crude NH_3 water by external application of steam instead of introducing the steam directly into the water; the amount of the latter would thus remain const. and it could be completely utilized. After being thus used several times the water would become enriched in fixed NH_3 and phenols to such an extent that it would be advisable to distil it with alkali to volatilize NH_3 and to treat it either with org. solvents or with activated C to recover the phenols. It is advisable not to wet the coals to an excess, as by increasing the amt. of water used for wetting the coal the vol. of NH_3-liquor obtained is increased and the concn. of the NH_3 in the liquor is lowered; it is desired to obtain liquors as concd. as possible. NH_3 obtained by the cycle process is considerably cheaper than that obtained by the old (lime water) process, but it is contaminated with CO_2 (60 g. per l. of soln.) and with H_2S (10 g. per l.). In the manuf. of $(NH_4)_2SO_4$ the cycle process cannot compete with the more advantageous direct method of obtaining this salt by washing the coke-oven gases with H_2SO_4. BERNARD NELSON

Technological notes. HUGO NOVAK. *Paliva a Topeni* **9**, 170-82(1927).—N. reviews recent methods applied in removing phenol from ammonia water, vacuum distn. of scrubbing oils in gas plants and coke plants, dry cleaning of illuminating gases, drying of air for blast-furnace stoves with silica gel, removal of CO_2 from gaseous mixts. in ammonia synthesis, and the production of gases with a higher heating value in generators for the complete gasification of coal. FRANK MARESH

Coal tar: its treatment and its applications. R. DUCHÊNE. *Science et Industrie* **12**, No. 174, 40-6(1928). E. H.

The rational utilization of coal-tar oils and pitch. L. TRABUC. *Chimie et industrie* Special No., 333-5(April, 1928).—Discussing the problem chiefly from the French economic standpoint, T. considers that all coal tar should be distd., the creosote oils being used for wood impregnation, the naphthalene and anthracene being used for the explosives and other chem. industries and the pitch being used for road-dressing in emulsified form. The disadvantages of using coal tar as such on roads are discussed, showing that the more volatile portions, which are removed by distn., slowly evap after being applied to the road and are lost. The "Association Routiére et Chimique" has devised a process which is now being used satisfactorily for emulsifying pitch just before applying to the roads and is marketing its products under the registered trade mark of "Arcite." A. PAPINEAU-COUTURE

Producer for low-temperature tar without tar recovery. J. HUDLER. *Feuerungstech.* **16**, 63-4(1928).—The tar in the gases from producers of this type is more profitably burned with the hot gas. The advantage of the type lies in its more uniform operation, not in the tar. ERNEST W. THIELE

Tar from peat of Ostashkov district. B. V. MAKSOROV. *J. Chem. Ind.* (Moscow) **4**, 755-8(1927).—U. S. S. R. possesses enormous deposits of peat which are easily mined and have a high content of org. matter. The tar obtained from the Ostashkov peat by distn. has been studied. After the removal of water the tar appears as a dark-brown unguent possessing a sharp odor. Its d_{18} is 0.9554. The amount sol. in concd. H_2SO_4 (unsatn.) is 80% by vol., Hubl I value is 98 89, Engler viscosity 3.2 at 50°. The tar oxidizes energetically in air, particularly on stirring and warming, and then blackens while emitting fumes of NH_3, amines and water. Its elementary compn. is: C 77.85, H 10.07, N 2.95, S 2.64 and O 6.49%. It differs from ordinary peat tar by its strongly alk. reaction and abundance of N compds. By fractionating 100 parts of the tar the following products are obtained: oil 65.9, residue 26.1, gases and water 8 parts. The oil has an exceedingly unpleasant odor; its lowest boiling (benzinic) fraction (up to 150°) represents only 1.3% of its wt.; its middle fraction (b. 190-200°) consists of a mixt. of cresols and xylenols (phenols); its heavy fraction gives on cooling paraffin crystals, m. 62.1, d_{20} 0.917. The compn. of the oil obtained by distn. of the Ostashkov peat tar is as follows: phenols 11.1, org. acids 1.6, org. bases 7.6, neutral O and S compds.

3.7, neutral N compounds of the type of pyrroles, indoles, etc., 6.4, solid paraffin 5.9, liquid paraffin hydrocarbons 27.2, cyclic hydrocarbons 18.6, unsatd. hydrocarbons 17.9%. The technical utilization of this peat tar is still an unsettled problem.
BERNARD NELSON

Desirable characteristics of coke: chemical. J. D. DAVIS. Bur. Mines, *Repts. of Investigations* No. 2884, 8 pp.(1928).—Coke in general should contain not more than 4% moisture, 2% volatile matter and 1.25% S. Metallurgical coke is limited to 0.01% P. Coke ash should have a fusing temp. above 2200° F. Foundry coke should contain at least 86% fixed C. The importance of reactivity in blast furnace and water gas coke is debatable; producer coke should have high reactivity while foundry and domestic cokes should have low reactivity.
D. GORDON

Determination of the reactivity of coke. D. J. W. KREULEN. *Z. angew. Chem.* 41, 498–501(1928).—A current of air is passed at a const. speed over a weighed amt. of the coke in a porcelain tube maintained at 700°, and the amt. of CO_2 evolved in a definite period of time is detd. The boat contg. the coke, which is in the cold part of the tube while the furnace is heating up, is pushed by means of a wire into the heated portion and 2 min. are allowed for it to reach 700°. Connection is then made to the CO_2 absorption app. (a tower contg. coke moistened with 30% KOH soln.), and absorption is allowed to proceed for 5 min. The increase in weight of the tower is taken as a measure of the reactivity.
B. C. A.

The calculation of coking times when oven conditions are changed. WERNER LOHRISCH. *Feuerungstech.* 16, 133–6(1928).—By collecting available data and making reasonable assumptions, L. is able to apply the mathematical theory of heat conduction to coke-oven problems. The results agree fairly well with practice.

Atomizable mobile liquid fuel. ARTHUR W. BURWELL (to Alox Chemical Corp.). U. S. 1,684,125, Sept. 11. Finely divided solid fuel such as coal is suspended in a colloidal gel formed from a normally liquid petroleum hydrocarbon mixt., *e. g.*, the material produced by catalytic oxidation and addn. of NaOH to fuel oil constituents.

Manufacture of peat coals. MAGNA DANNEVIG. Norw. 45,056, April 16, 1928. Mech. features of app. The hot gases from the drying and carbonizing process contg. a considerable amt. of combustible substances are burned again in a sep. app., the heat being utilized for a preliminary drying and heating of the peat mass.

Oils from coal, etc. I. G. FARBENIND. A.-G. Brit. 283,545, Jan. 13, 1927. Coal or other suitable carbonaceous materials are treated, at pressures of 75 atm. or higher and which may be up to 1000 atm., and at temps. (preferably about 300–400°) below the coking temp. of the extg. agent with hydrocarbon materials or their suitable derivs. which are liquid under the reactive conditions and which contain substances b. 100–300°. Among the extg. agents which may be used are: xylene, cresol, hydrogenated naphthalenes, aniline, alk. substances decompg. coal, oils b. above 180° obtained in the process, oils from the distn. or low-temp. carbonization of coal, lignite or mineral oils or from the destructive hydrogenation of coal, tars, mineral oils or the like or from

the catalytic hydrogenation of oxides of C under pressure. These oils may also be mixed with those b. above 300° as described in Brit. 282,691 (*C. A.* **22**, 3763). Over 50% of the coal treated may be converted into liquid oils. Catalysts and gases free from H may be present, and the process may comprise stages of successively increasing pressure.

Gas and oil production. FREDERICK T. SNYDER (to Canada Super-Coal, Ltd., to S. R. Allen and H. H. Hansard). Can. 283,635, Sept. 25, 1928. Gas and light oils are produced by feeding fuel to a gas producer, distg. said fuel by passing in contact therewith the gases of the producer, burning the solid product of said distn. in the base of the producer with a blast of air, injecting heavy oil as a cooling fluid into the products of said combustion above the zone of combustion, and subsequently increasing the amt. of gas flowing in contact with said fuel by passing additional gas into said producer above the zone of said fluid injection, and fractionally condensing the condensable distillates to sep. them from each other and from the gaseous and the solid products.

Destructive hydrogenation of carbonaceous material. CARL KRAUCH AND MATHIAS PIER (to I. G. Farbenind. A.-G.). Can. 282,876, Aug. 28, 1928. Carbonaceous materials are destructively hydrogenated by bringing the materials into intimate contact with a hydrogen-contg. gas under a pressure of at least 50 atm. and at a high temp. in the presence of a catalyst, with one or both reagents in a state of fine distribution in one another. Cf. *C. A.* **22**, 2463.

Treatment of carbonaceous material. HUBERT DEBAUCHE. Can. 282,960, Sept. 4, 1928. Carbonaceous material is subjected to low-temp. distn. and the semi-coke while retaining sufficient heat is successively and uninterruptedly submitted to screening, grading, mixing and agglomerating, thereby avoiding the necessity of any intermediate heating.

Apparatus for the distillation of carbonaceous material. EDWARDO M. SALERNI. Can. 283,205, Sept. 11, 1928. A still for carbonaceous material has an upper drying chamber through which the charge is progressively fed while being agitated and disintegrated and in counter flow to the hot gases emerging from a lower distn. chamber in which are located a plurality of troughs through which the charge is passed and agitated. The spent solid material is passed to a cooling means. The hot volatile constituents are freed from dust and condensed.

Carbonizing stove. JOSEF PLASSMANN (to Chem. Techn. Ges. m.b.H.). Can. 283,562, Sept. 25, 1928. A stove for carbonizing fuels comprises a plurality of superposed circular cells heated from above and below and at the inner wall, and enclosed by a rotatory exterior jacket to which are attached the filling means and the discharge means.

Combination coal-dust and gas burner. MICHAEL ELBERT. Ger. 451,911, Nov. 4, 1927.

Method and apparatus for operating furnaces for steam boilers and superheaters. AKT.-GES. BROWN, BOVERI & CIE. Ger. 451,926, Oct. 29, 1927. The cooler waste gases are returned to the fire or combustion chamber and introduced as a flat or fan-shaped stream which more or less envelopes the flame.

Facilitating the charging and discharging of furnaces used in the dry distillation of bituminous materials. PATENTAKTIEBOLAGET GRÖNDAL-RAMEN. Ger. 452,008, Nov. 26, 1927. Open-ended trays are placed in layers on a car. The car rolls on wheels into a frame or cage having plates which form covers for one end of the corresponding tray. The cage rotates around a horizontal pivot. The cage contg. the car and trays is then rotated to a slanting position for charging. A channel attached to one end of the cage serving as a side cover for the trays has openings corresponding to the open ends of the trays and while the cage is in the slanting position it is charged from a hopper above. After charging, the cage is rotated to its horizontal position and the car with the loaded trays rolled into the furnace, where distn. takes place. For discharging a similar app. is used which has an arrangement for loosening the material that has baked into the trays.

Centrifugal air cleaner for internal-combustion engines, etc. CHARLES G. HAWLEY (to Centrifix Corp.). U. S. 1,684,023, Sept. 11.

Apparatus for generating illuminating and fuel gas. ERNST GOFFIN. Ger. 451,976, Nov. 4, 1927.

Plant construction (with twin generators) for making water gas and producer gas. J. Lowe. Brit. 283,909, Jan. 20, 1927.

Production of water gas and hydrogen. Herbert A. Humphrey (to Imperial Chemical Industries, Ltd.). Can. 281,814, July 17, 1918. In low-temp. carbonization and gas manuf. high coking coal is preheated in presence of O to control its coking properties; the product is carbonized at a temp. below 600° to produce lump semi-coke; the semi-coke is gasified with steam and the gas is treated with steam at high temp. to decompose the CH_4. The gas is used for the synthesis of *methanol* with the single passage of the gas over a catalyst, and the residual gas is used for *NH_3 synthesis*, after replacement of the CO by H, removal of CO and addition of N.

Retort seal. Paul G. Strassmann (to Indugas Industrie- und Gasofen -Baugesellschaft m.b.H.). Can. 282,710, Aug. 21, 1928. A seal for the base of a retort consists of an upper dry and non-gastight closure and a coöperating lower wet closure.

Purifying tars, tar oils, etc. J. Karpati and M. G. Hubsch. Brit. 283,569, Jan. 15, 1927. Tars, tar oils and other tar derivs. are treated for the removal of phenols by a solvent for phenols dild. with water (suitably at temps. of 90–150° and pressures of 1.5–6 atm.). Me, Et and Pr alcs., acetone, CH_2O and AcH may be used as solvents, and the alc. may be of 20% strength. The effectiveness of the solvents is improved by the further addn. of substances such as NaCl or Na_2SO_4 which reduce the soly. of the hydrocarbons. The more acid phenols are more easily sol. and the process may be conducted to effect fractional sepn. of different phenolic products.

F. M. ROGERS

The advantages of physical methods for the refining of petroleum. A. Guiselin. *Chimie et industrie* Special No., 289–91 (April, 1928).—A discussion of the advantages and possibilities of phys. processes for the refining of petroleum, such as filtering through clay or treatment with Me_2CO, EtOH or SO_2. A. Papineau-Couture

Scientific foundations of the refining of petroleum. I. Gas and gasoline. A. E. Dunstan. Anglo Persian Oil Co. *J. Roy. Soc. Arts* **76**, 922–42 (1928). **II. Distillation methods.** *Ibid* 945–63. **III and IV. Refining of petroleum distillates.** *Ibid* 965–81, 985–98.—Four lectures on the modern art of petroleum refining, emphasizing what is known of the scientific principles underlying the major operations. G. Calingaert

Cracking under low pressure. K. Kostrin. *Neftyanoye Khozyaistvo* **12**, 39–45 (1927); *Chem. Zentr.* **1927**, 1523–4.—A comparatively low pressure is used nowadays to crack hydrocarbons. This is due to the demand for more unsatd. hydrocarbons, which are desirable anti-knock compds., as compared with higher pressures used before to eliminate the unsatd. compds. A paraffin mazout from Surakhanui (Baku) cracked in a tube still at 480–490° and 2.5–3.0 atm. gave 33.5% distillate and 59.2% residues. The residue had a flash point 12° below that of the original mazout and was suitable for fuel. The initial b. p. of the distillate was 90°; 39% distd. off below 150°. The benzine obtained contained 13% unsatd. hydrocarbons. This quantity could be decreased to 6.5% by treatment with fuller's earth, probably by polymerization of unsatd. compds. The boiling range moves simultaneously towards higher temps. H_2SO_4 acts in the same direction but more powerfully; therefore it could not be recommended for treatment. A. A. Boehtlingk

Cracking in the liquid phase. A. Dobryanskii and A. Mureyeva. *Neftyanoye Khozyaistvo* **12**, 411–3 (1927).—The cracking of oil is generally carried out in the vapor phase. D. and M. investigated the decompn. by heat in the liquid phase at 405–415° and under atm. pressure. Lubricating oils and paraffin wax were cracked. The gas obtained was collected in fractions of 500 cc. and each fraction separately analyzed; the cracking distillates were also collected separately and analyzed. It was possible to study the chem. changes during the run. Ethylene, propylene, heavy hydrocarbons and the satd. hydrocarbons by subtraction were detd. according to Dobryanskii (*Neftyanoye Khozyaistvo* **9**, 565) in the gases obtained. The amount of ethylene and heavy hydrocarbons decreases, and the amt. of satd. hydrocarbons increases with the progress of decompn. The longer side chains of aromatics are probably the first to be split at the beginning of the decompn., followed by a second splitting which leads to the formation of satd. hydrocarbons. The sp. gr. of the distillate increases and its content of low-boiling (below 150°) hydrocarbons decreases with the progress in decompn. The

cracking is not affected by the presence of pumice, coke, Cu or Fe shavings.
A. A. Boehtlingk

Comparison of the reaction products obtained by the cracking and by the berginization of paraffin. H. I. Waterman and J. N. J. Perquin. Ecole technique sup. de Delft. *Chimie et industrie* Special No., 244–57(April, 1928).—See *C. A.* **22,** 497.
A. Papineau-Couture

The combustion of hydrocarbons. Hydroxylation and (or) peroxidation. W. A. Bone. *Nature* **122,** 203–4(1928).—B. reviews a few of his early expts. on slow combustion of hydrocarbons and points out that the new peroxidation theory, while attractive on certain counts, does not contradict the evidence for the hydroxylation theory. Reply. A. Egerton. *Ibid* 204.—The action of anti-knocks indicates the existence of a chain reaction depending on the formation of some active product. This suggests the intermediate formation of active unstable peroxide, the active products formed by reorganization or decompn. of the compd. being able to continue the reaction chain.
G. Calingaert

Improvement of the combustion of hydrocarbons (in explosion engines) by nascent oxygen obtained by mixing the liquid fuel with previously oxidized terpenes. André Laurent. *Chimie et industrie* Special No., 319–23(April, 1928); cf. *C. A.* **21,** 3444.—"Targol" consists of oxidized terpenes, the exact nature of which is not divulged. Attempts to activate the terpenes by treatment with O_3 were unsatisfactory, because its excessive reactivity gives irregular results with liability of explosion in the carburetor or excessively violent explosions in the motor cylinder. Preliminary oxidation with O_2 gives very satisfactory results, as shown by the fact that about 25,000 automotive engines are now running regularly with gasoline mixed with "targol" in latitudes ranging from Belgian Congo to Norway and Sweden. The merits of this mixt. are discussed in the light of its actual performance in every-day operation from the standpoints of fuel economy, increased power, mech. and chem. effects on the motors, effects on lubrication, effects on public health. A. Papineau-Couture

Panuco oil field, Mexico. Charles L. Baker. *Bull. Am. Assocn. Petroleum Geol.* **12,** No. 4(1928).—The oil of the Panuco section varies in gravity from 12.5° to 12.9° Bé., contains 3.5 to 5.7% S, an av. of 3.5% (max. 5%) gasoline, and has an asphaltic base. Topila oil varies from 15° to 17.2° Bé. Ebano oil averages from 10.6° to 11.8° Bé. The temp. of the Panuco oil ranges from 90° to 120° F. The temp. ordinarily raises a few degrees upon the appearance of salt water. The compn. of Panuco gas is 50 to 98% CO_2, with CH_4 and possibly other petroleum derivs. taking 2nd place, and H_2S 3rd. There is also probably a little SO_2. Most of the gas will not burn. The CO_2 is derived from 2 sources: (1) the metamorphic action of hot magmas, intruding limestone (calcination) and eruptive after-effects have liberated vast quantities of it, and (2) a part has been derived by the dissolving action of the underground waters, already highly charged with the same gas from the first source, and therefore forming a solution which readily dissolves the limestone. The H_2S appears to be either entirely of magmatic origin or derived from the reduction of sulfate in soln. in the water, since practically all the pyrite and chalcopyrite found in drilling samples are entirely unaltered. The H_2S has evidently been the leading agent in the formation of tar from the oil, making it excessively heavy. The O of the asphalt can be partially or entirely replaced by S and the Panuco oil contains S in the elementary condition up to the satn. point for S at the prevailing temps. The total salinity of the *waters* analyzed ranges from 2.8 to 7.2%. It is apparent from this variation that the waters have different sources, and that there is no mingling of the waters even in the near-by fracture zones. The high percentage of K is the most remarkable feature. Three sources of K are: (1) from acidic holocrystalline rocks, (2) from potash-bearing desiccation sediments associated with possible gypsum-bearing beds known in the cordillera or other saline residues of older date, and (3) from leaching of the acidic tuffs of the Upper Cretaceous. Compared with sea water there has been the addn. of K, Ca and CO_2 radicals and the subtraction of the SO_4 and Mn radicals. (A table with 11 analyses is given.)
C. L. Cooper

Limestones as a source of oil. Parker D. Trask. *Bull. Am. Assocn. Petroleum Geol.* **12,** No. 5(1928).—A distn. of limy oozes in 2 widely sepd. regions, the Florida Bay and the Gulf of Batabanó, gave a max. yield of 2.5 gal. per ton. The chance for possible contamination of oil from surface water or from seepage from a buried non-limy formation is negligible. The fact that 1% of the total wt. of these sediments can be caused to become volatile and condense into a liquid is very significant, and indicates that such beds are potential future source beds. C. L. Cooper

Jamin action—what it is and how it affects production of oil and gas. Stanley

C. HEROLD. *Bull. Am. Assocn. Petroleum Geol.* **12**, No. 6(1928).—Jamin action is a phys. phenomenon due to alternating globules of liquid and bubbles of gas in channels of capillary dimensions. A natural reservoir may be described as a huge bundle of capillary tubes radiating in all directions from the well. The globules and bubbles offer a resistance to any hydrostatic pressure tending to push the fluids toward the open well. If this hydrostatic pressure is of sufficient intensity, it overpowers the combined resistance of all globules located on the radiating lines, but if it is not of sufficient intensity, these globules and bubbles may be said to dictate the conditions of production from the well. These alternative conditions with respect to pressure and resistance determine volumetric and capillary controls, respectively. Particular emphasis is placed upon the effects of Jamin action with regard to the rate of production, vol. produced from the well, and percentage of recovery from the sands by natural flow; also the features accompanying the use of pumps and gas lifts are discussed. The force drive is given a brief review, and the paper concludes with a description of the method of discriminating in the field between volumetric and capillary controls.
C. L. COOPER

The effect of pressure on the migration and accumulation of petroleum. F. M. VAN TUYL AND R. C. BECKSTROM. *Bull. Am. Assocn. Petroleum Geol.* **10**, No. 10 (1926).—This paper describes several expts. in which various types and arrangements of sedimentary materials, after being charged with oil and water in such a way as to simulate conditions in nature, were placed in a steel cylinder and compacted at high pressures. The results are believed to justify the conclusion that the compaction of petroliferous sediments either as the result of the wt. of the overlying load or of deformation is an important cause of the movement of oil into reservoir rocks.
C. L. COOPER

A quick method for determining porosity. W. L. RUSSELL. *Bull. Am. Assocn. Petroleum Geol.* **10**, No. 10(1926).—R. describes a quick method for detg. porosity in oil and gas sands by means of a reasonably cheap app. that can be easily carried in field work. The novel feature of the method described lies, not so much in the mechanism as in the use of $CHCl_2.CHCl_2$, which possesses the advantageous features of readily entering the pore space of all types of sand without causing disintegration and without rapid evapn. An idea of the accuracy of this method is given by an analysis of each possible source of error, both in method and app., and the conclusion is reached that the $CHCl_2.CHCl_2$ method affords a reasonably accurate means for the detn. of porosity, especially useful for rapid work.
C. L. COOPER

The effect of flooding oil sands with alkaline solutions. R. C. BECKSTROM AND F. M. VAN TUYL. *Bull. Am. Assocn. Petroleum Geol.* **11**, No. 3(1927).—This paper gives the results of a series of expts. on the flooding of oil sands with ordinary water and solns. of various kinds and concns. The most satisfactory results were obtained by the use of dil. alk. solns. of salts of the weak acids and strong bases, Na_2CO_3 being the most effective of all. Several types of app. were employed, including in one series of expts. blocks of Dakota sandstone, which, after being charged with oil under pressure, were subjected to flooding tests.
C. L. COOPER

Viscosity determinations on less than 200 cc. of oil. L. BLOCH AND A. DOBRYANSKII. *Neftyanoye Khozyaistvo* **12**, 554–7(1927); *Chem. Zentr.* **1927**, 1531.—The viscosity in Engler degrees is measured by the time of flow of 200 cc. of oil. In order to make possible the detn. on less than 200 cc. oil, and thus in less time, the following equation was developed for the relation between time of flow and vol.: $T/t = {}^1/_3[(800/v) - 1]$, in which T is the time of flow of 200 cc. and t the time of flow of v cc.
A. A. BOEHTLINGK

The problem of gasifying heavy oil and its modern solution. JOSEF SIMON. *Feuerungstech.* **15**, 313–5(1927).—The Hahn oil burner is described. The oil is heated to 300–350° with a metal bath. The vapors are mixed with highly superheated steam and burned in a Bunsen type burner. Something analogous to the water-gas reaction takes place, the flame being blue.
ERNEST W. THIELE

Sulfur compounds in transformer oil. E. FERBER. *Z. angew. Chem.* **41**, 680–2 (1928).—The complete removal of S from the heavier distillates of petroleum or lignite tar, which is necessary before hydrogenation, is effected by treatment with metallic Na. The carbonaceous residue was acidified with dilute HCl and extd. with light petroleum, from which a yellow oil was obtained by evapn. This proved to be a mixt. of disulfides, from which, by reduction, amyl, heptyl and octyl mercaptans were isolated.
B. C. A.

The stability of transformer oils. A. R. MATTHIS. *Chimie et industrie* Special No., 324–7(April, 1928).—See *C. A.* **22**, 1467.
A. PAPINEAU-COUTURE

Moisture in oils used in the electrotechnic industry. Rapid method for the approximate determination of their moisture content. A. R. MATTHIS. *Chimie et industrie* Special No., 328–32(April, 1928).—See *C. A.* 21, 1882. A. P.-C.

A study of the pyrogenation of mineral oils. G. DIXMIER. *Chimie et industrie* Special No., 283(April, 1928).—A no. of lubricating oils subjected to Conradson's test gave results varying from 0.11 to 2%. The same oils subjected to 50-hr. tests in airplane motors did not show differences in the fouling of the motors having nearly as large a ratio as 1:20. Promising results have been obtained in developing a test based on heating the oil 150 hrs. at 150° and detg. the residue insol. in low-boiling petrolic ether. A. PAPINEAU-COUTURE

A study of the sulfuric acid reaction of mineral oils. M. CORNET. *Chimie et industrie* Special No., 281–2(April, 1928).—The H_2SO_4 test of mineral oils (dissolving 50 cc. of oil in 50 cc. benzine, agitating with 10 cc. concd. H_2SO_4, letting stand and noting the increase in vol. of the acid layer) was introduced on account of the notion that it gave a measure of the tendency to formation of tarry matter when the oil is used in motors. An attempt was made to det. if possible the amt. of polymerization taking place in the test (by detg. the mol. wt. cryoscopically before and after the test) and also to ascertain what changes, if any, take place in the nature of the hydrocarbons (by detg. the crit. soln. temp. in $PhNH_2$). On treating various oils with 40% H_2SO_4 (on the amt. of oil) at 20° and at 100° the changes in mol. wt. were so small as to be without significance. When the oils were treated with H_2SO_4 in the cold there was no appreciable change in the crit. soln. temp.; but at 100° there was a noticeable increase in the crit. soln. temp. Oils which were heated in absence of H_2SO_4 showed no change in crit. soln. temp. C. concludes that there is no relationship between the H_2SO_4 test and the action of heat in the motor on the oil; and this conclusion is further strengthened by the fact that oil can be subjected to the H_2SO_4 test, purified, and repeatedly treated in the same way, the results being practically the same each time. A. PAPINEAU-COUTURE

The distillation of shale oil from a liquid phase. I. II. ERNST VON PEZOLD. *Chem.-Ztg.* 52, 541–2, 562–4(1928).—P. reviews previous work in which oil shale was heated in the presence of a solvent. In his expts., P. uses shale oil as a solvent, and concludes that this increases the yield of oil materially. G. CALINGAERT

Working up turbine distillate for white oil. S. A. NAZAROV. *Neftyanoye Khozyaistvo* 14, 772–4(1928).—Turbine oil distillate was treated 12 times in succession with small portions of H_2SO_4 (contg. 20% free SO_3) at low temp., neutralized with 4.5° Bé. NaOH, treated with fuller's earth and pressed at a temp. of 70°. In this treatment the d_{15}^{15} decreased from 0.89362 to 0.87276, the flash point increased from 184° to 187°, the I no. decreased from 1.643 to 0, the sludge from 4.8% to 0, the abs. viscosity from 0.563 to 0.409. The strong odor disappeared. Analyses are given of the sludge recovered from each of the H_2SO_4 treatments. The acid has polymerizing, drying, oxidizing and solvent action in the first portions and sulfonation action in the following treatments. The amount of acid used was 1.6% by wt. for the first treatment and increased gradually to 6.57% calcd. on the amount of oil left for the 12th treatment. The loss in oil was 3.98% for the first treatment and 0.3% for the last. After the seventh or eighth treatment the change in the quality of the distillate was hardly noticeable. The acid sludge especially from the last treatments can be successfully applied for treatment of cylinder and machine oils. A. A. BOEHTLINGK

Construction and operation of oil stills. L. A. MEHLER. *Fuels and Furnaces* 6, 1073–7(1928).—Various types of conduction and radiant-heat stills are described, with diagrams, and their methods of operation, together with the limitations of each kind of still, are considered in this paper. Formulas used by the combustion engineer in calcg. the quantity of heat transmitted to the still and recirculating ratios for economy in operation are given. J. W. SHIPLEY

The use of tallöl (liquid rosin) in the alkali wash of petroleum distillates. K. DITTLER. *Chem.-Ztg.* 52, 577–8(1928).—Tallöl (Wastoil, liquid rosin) is a by-product of the cellulose industry. It is obtained in Scandinavia by treating rosin-rich conifer wood with 10 Bé. NaOH, and hydrolyzing the soaps obtained by mineral acids. A typical dry product showed: acid no. 157.3, sapon. no. 167.9, I no. 115, fatty acids 48.5%, rosin acids 43.3%, unsaponifiable matter 8.2%. Its odor precludes its use in making soft soaps. It is a good substitute for oleic acid to prevent the formation of emulsion in the alkali wash of petroleum distillates. The best results are obtained with 3 to 5 Bé. NaOH. Mix well, heat with indirect steam to at least 85°, and draw the clear soln. after 12 hrs. of settling. The oils refined with this soln. may take a brownish coloration, but they are clear and stable. G. CALINGAERT

Study of two gasolines with high olefin-hydrocarbon content obtained by distillation of coal and of shale. R. Garnaud. *Chimie et industrie* Special No., 275–6(April, 1928).—The detn. of olefins by treatment with cold concd. H_2SO_4 as it is generally carried out is very inaccurate with high olefin contents, because the olefins undergo considerable polymerization and the polymers dissolve in the hydrocarbons which were not attacked by the H_2SO_4. G. modified the method by sepg. the unattacked residue and distg. to the same temp. as the end point of the distn. of the original gasoline, the dissolved polymers being less volatile. Comparative detns. on an aviation gasoline produced from shale oil gave 28% olefins by the ordinary method and 71% by G.'s modification, the latter agreeing fairly well with the Br no. detn. (107, equiv. to 65.5% olefins calcd. as heptylene). The 2 gasolines examd. contained a certain amt. of diolefins, which tend to polymerize in use in the motor, but which lab. tests showed could easily be removed by filtration through fullers' earth. A. P.-C.

Tension of benzine vapors. I. M. Polzik. Izvestiya Teplotek. Inst. *Bull. Inst. Fuel Research* (Russia) **1927**, No. 4, 1–13.—The static method of detn. of vapor tension in benzine indicates the necessity of considering not only the liquid present whose vapors sat. the space but also the proportion of vols. between the liquid and vapor phases. A new factor is introduced in the equation of Stanley Lewis, which is changed into $P = f(T, m_1, m_2, m_3, \ldots\ldots v_1/v_v)$, where T is the abs. temp., m_1, m_2, m_3, ... are mol. quantities of each component in the liquid phase and v_1/v_v is the proportion between the vols. of the liquid and vapor phases. Narrow benzine fractions do not indicate this dependency. A. A. Boehtlingk

Anti-knock compounds and the adiabatic ignition of hydrocarbons. André Pignot. *Chimie et industrie* Special No., 277–8(April, 1928); cf. Aubert, P. and Villey, *C. A.* **22,** 863. A. Papineau-Couture

The influence of tetraethyl lead on the detonation of gaseous air-fuel mixtures. R Duchêne. *Compt. rend.* **187,** 200–1(1928); cf. *C. A.* **22,** 1476.—Further explosion expts. are run on gaseous C_6H_{14}-air mixts. at 80°, alone and with the addn. of 5% $PbEt_4$ to the C_6H_{14}. The photographic record of the propagation of detonation in the absence of $PbEt_4$ is weakened or no longer present when $PbEt_4$ is added. This demonstrates the anti-knock effect of $PbEt_4$ in homogeneous gas mixts. G. C.

The problem of detonation in explosion motors. E. Pistolesi. *Ann. scuola ing. Padova* **3,** 386–92(1927).—Callendar's nuclear theory and Smith's theory of pyrophoric effect are suggestive. By thermodynamic analysis the influence of the rate of compression and of the initial temp. of the mixt. on detonation can be evaluated. It shows that an increase of the rate of compression and of the initial temp. increases the mass of unburned mixt. which detonates under the compression of the burned fraction. It can be assumed that above a certain increase of the detonating mass the effect of detonation will attenuate itself, and the max. effect will take place when the detonating portion is about 50%. This would indicate that the temp. and compn. should be increased decidedly except for the danger of self-ignition. Therefore, the best conditions to avoid self-ignition increase the dangers of detonation. A. W. C.

The formolite reaction. A. Dobryanskii. *Neftyanoye Khozyaistvo* **12,** 57–64 (1927); *Chem. Zentr.* [II], **1927,** 1530.—The formolite reaction was systematically investigated to det. the source of trouble in formolite tests. Methylal was taken to replace the commercial aldehyde, which varies greatly in concn. A soln. of benzene in benzine was used as aromatic. The following items were investigated: (1) The concn. of H_2SO_4. Tests were made with 6.6 cc. methylal and 10 cc. of H_2SO_4 on 1 g. benzene in 9 cc. benzine. The formolite number increased from 2.8 with 85.6% H_2SO_4 to 126.9 with 93.0% H_2SO_4. (2) Duration of the reaction. The highest and stable formolite number is obtained in 10 min. by using the following proportions: 1 g. benzene + 9 cc. benzine + 7.5 cc. 93.6% H_2SO_4 + 5 cc. methylal. (3) The quantity of H_2SO_4. If 1 g. methylal is used for 1 g. benzene, the highest formolite no. unchanged by the addn. of H_2SO_4 is obtained with approx. 6–8 cc. of H_2SO_4. This is the max. of H_2SO_4 when for 1 g. benzene 2, 3, or 4 cc. methylal is used; an excess of H_2SO_4 is harmful in this case. (4) The best proportion of methylal and H_2SO_4 is 1.5 vol. H_2SO_4:1 vol methylal. (5) The formolite number is independent of the amount of the above optimal mixt. if more than 10 cc. is taken for 1 g. benzene; the formolite number appears smaller in smaller quantities of mixt. The formolite pptn. is qual. different if the quantity of mixt. is considerably below the requirement; an oil with diphenyl odor is then formed. D. gives the name α-formolite to this condensation product; the d[illegible] product which is obtained through treatment with H_2SO_4 in excess and which becomes horn-like when dry is called γ-formolite; and the substance formed under optimal conditions is called β-formolite. (6) The concn. of benzene in benzine should

not be below 10%. In detg. the formolite number of hydrocarbons difficultly sol. in benzine the methylal and H_2SO_4 treatment should be repeated. A. A. B.

The formolite reaction. A. Dobryanskii and M. Olevskii. *Neftyanoe Khozyaistvo* **12,** 227-31(1927); *Chem. Zentr.* [II], **1927,** 1530-1; cf. preceding abstr.—A similar investigation was made with a 40% soln. of CH_2O instead of methylal. The results were not so accurate. If formalin is added first to benzene in benzine and the H_2SO_4 later, much less formolite is formed than when the H_2SO_4 is added first. All observations below were made according to the last method. (1) With 8 cc. 10% benzene solution + 16 cc. H_2SO_4, the highest formolite yield is with 6% formalin. (2) With 10 cc. benzene soln. + 5 cc. formalin the highest yield is obtained at about 20 cc. of H_2SO_4; but the yield is affected very little by excess of H_2SO_4. (3) With 1 cc. of 79% benzene soln. and 1 vol. formalin to 4 vols. H_2SO_4 in the reagent, the max. of the reagent is 20 cc. For 1 vol. formalin to 3 vols. H_2SO_4, the max. in reagent is about 30 cc.; for 1:2.5 the max. is about 25 cc. The highest formolite number was obtained with the proportion 1:3. (4) With 7 cc. formalin and 21 cc. H_2SO_4 the highest formolite number is obtained with 2.6 g. benzene. It was found to be 124 for these optimal conditions; *i. e.,* it agrees in this case with the most favorable numbers obtained when methylal is used. One mol. benzene is required for 3 mols. of HCHO in the optimal mixt.; the wt. of the product formed (124 parts from 100 parts benzene) is considerably smaller than corresponds to the expression $C_6H_6 + 3CH_2O - 3H_2O$. A part of HCHO was evidently used always for side reactions. The high sensibility of the formolite number against the amount and concn. of the aromatic hydrocarbons makes the detn. of aromatic hydrocarbons in unknown mixts. problematical. The formolite number can at best be used only for comparisons. A. A. Boehtlingk

Insulating oils. G. Stadnikov and Z. Vozzinskii. *Neftyanoe Khozyaistvo* **12,** 694-6(1927); *Chem. Zentr.* [II], **1927,** 1915.—The sludge formed in transformer oils has its origin in the condensation of oxidation products formed from the oil. This condensation is greatly favored by naphthenesulfonic acids. The formation of sludge is frequently accompanied by a decrease in acidity of oil due to the condensation of acids; the decompn. of oil could not be measured by its acidity for this reason. Proofs of the condensing action of the naphthenesulfonic acids: When refined solar oil is heated with AcOH and cyclohexanol in a CO_2 atm. only esterification takes place if naphthenesulfonic acids are absent. In the presence of naphthenesulfonic acids sludge is also pptd. Sludge is formed by AcOH without alc. in the presence of naphthenesulfonic acids; also from acids with ketones and aldehydes. A light yellow oxidation product is obtained if air is led through transformer oil at 160° in the presence of a Cu gauze. The acidity of oil when heated with naphthenesulfonic acids is decreased, forming sludge. Naphthenesulfonic acids can be detected by this condensation method. The AcOH becomes colored when oil is heated with 4% AcOH and 2% AcOH (a part of the AcOH must remain undissolved); the intensity of color depends on the amount of naphthenesulfonic acids present in the oil. No darkening was observed in pure oil heated at 100° for 18 hrs. A. A. Boehtlingk

Oxidation of insulating oils. N. A. Butkov. *Izvestiya Teplotech. Inst.* (*Bull. Inst. Fuel Research* (Russia)) 1927, No. 4, 37-40.—B. reviews the work done by other authors and himself. The high oxidation of mineral oils is explained by catalysis. Catalytic oxidizing agents can be metals, soaps and org. compds. (autoxidants). Stadnikov's theory is criticized (*C. A.* **20,** 2634). A bomb, enameled on the inside and provided with a pressure gage, was charged with 10 cc. of oils of various origins and O at 14 atm. This app. was heated from 3 to 5 hr. up to 150°. Anti-oxidants such as β-naphthol and β-naphthylamine proved to be very effective. The formation of CO_2 and CO was observed and detd. either analytically or by calcn. from the increase in pressure. The following detns. were made in the oils after the expt.: acidity, sapon. value, excise resins, sediment formed by treatment with Na_2O_2. Highly refined oils are unstable toward oxidation, particularly oils treated with fuming acid. Unrefined oils are more resistant to oxidation. Refined oils when mixed with unrefined distillate of the same oil (25%) become more stable. The oxidation processes in oils are divided into: (1) Oxidation of impurities present (sludge, unsatd. hydrocarbons, etc.). The oil becomes stable if they are removed. (2) Oxidation of the oil hydrocarbons. Under the best conditions such oxidation is very slow; the rate depends on the structure of the oil hydrocarbons. Transformer oils can be oxidized faster by catalytic action. A. A. B.

The direct current conductivity of insulating oils. D. H. Black. *Phil. Mag.* [7], **6,** 369-84(1928).—A theory is put forward to account for the absorption current in liquid dielectrics. It is assumed that contact resistances are formed at one or both

electrodes by the passage of an elec. current, this causing the well-known decay of current with the time the potential has been applied across the electrodes. Exptl. support of the theory is given, and it seems capable of explaining in a simple manner the anomalous cond. phenomena observed in liquid dielectrics under direct current stresses. GEORGE GLOCKLER

Reviews of colloid technic. IV. Lubrication. C. WALTHER. *Kolloid Z.* **45**, 374–8(1928).—A review covering the various theories and formulas propounded in recent years (21 references) and the technical developments in the field of lubrication (19 references). G. CALINGAERT

Tar-formation number and stability of lubricating oils. BAUM. *Erdöl u. Teer* **4**, 423(1928).—It is contended that the tar-formation no., by the sepn. method, which shows the alteration of the oil on heating with passage of O_2 through it, is no criterion of stability in use because it does not take into account the catalytic effect of the metals present in the bearing, which may greatly predominate over the effects of heat and O_2 alone. The increases in the tar-formation nos. of various oils, after periods of use, showed great variation and were out of all relation to the original nos. The method is further objected to on the ground that it requires too long a time. The sp. gr., acid and sapon. nos. and H_2SO_4 reaction are claimed to be sufficient for characterization and the tar no. of Kissling, which can be detd. in a few minutes, for the detn. of the tarry constituents, if desired. F. S. GRANGER

Detection of paraffin in ceresin. D. HOLDE AND K. H. SCHÜNEMANN. *Z. angew. Chem.* **41**, 368–75(1928).—Wax-like products from Polish and Caucasian ozokerite, consisting chiefly of isoparaffins, are refined with H_2SO_4 and worked up as ceresin. Paraffin is frequently added to a ceresin, and this addn. was usually detected by fractional pptn. with alc. from chloroform soln., the fractions being examd. in a refractometer; the *n* of a ceresin is higher than that of a paraffin. A no. of samples of ceresin, m. 60–87°, and of paraffins which may be mixed with them, m. 50–60°, have been examd. and it is found that the latter are less easily pptd. from soln. and have much lower *n*s except in the single case of a Rangoon paraffin. The sp. gr. of paraffins is 0.867–0.915, and of ceresins 0.912–0.943; molten paraffins are less viscous than ceresins. Treatment with chlorosulfonic acid or 30% fuming H_2SO_4 provides still further distinction, as the extent of reaction is small with paraffins, but may involve up to 70% of a ceresin. Examn. of mixts. of pure ceresin with known amts. of different paraffins showed that treatment with acids combined with pptn. from soln. provided the most sensitive test for detection of added paraffin. B. C. A.

Automatic constant-temperature bath for asphalt tests. C. W. BETZ. *Eng. News-Record* **101**, 242–3(1928).—An illustrated description of an automatic electrically controlled circulating system in use in the lab. of the Bur. of Tests and Specifications, County of Allegheny, Pittsburgh, Pa., which regulates the temp. of water to within 0.1°. R. E. THOMPSON

Action of catalyzers on the distillation of wood. G. DUPONT AND R. LASCAUD. *Chimie et industrie* **Special No.**, 284–8(April, 1928).—See *C. A.* **21**, 3739. A. P.-C.

A practical wood-coking furnace. ANON. *Feuerungstechnik* **15**, 320–1(1927).—The retort described is wrought iron, vertical, larger toward the bottom, and externally fired. It is not continuous; tar appears to be the only by-product. E. W. T.

Centrifugal mixers [for acid treatment of crude oils] (BUHTZ) 1. The propagation of combustion in mixtures of hydrocarbons and air (DUCHÊNE) 24. Identification of oil field waters by chemical analysis (REISTLE) 14. Attack of cotton by mineral oils at higher temperatures (STÄGER) 25. C compounds of the magma (HELLMERS) 8. Radiometric exploration of oil deposits (BOGOIAVLENSKY) 3. Determining absolute viscosity of paraffin oils, lubricating oils, etc. (RAASCHOU) 2. The negative catalysis of autoxidation-antioxygenic activity (MOUREU, DUFRAISSE) 2. Filter for petroleum (U. S. pat. 1,684,025) 1.

DUNSTAN, A. E.: **The Scientific Foundations of the Refining of Petroleum.** Cantor Lectures. London: Royal Society of Arts. 95 pp. 3s.

Decolorizing, clarifying and purifying petroleum oils. HAROLD L. KAUFFMAN and IRWIN A. CLARK (to Harold L. Kauffman). U. S. 1,684,035, Sept. 11. The oil is mixed with finely ground filtering material such as fuller's earth and agitated with superheated steam; the mixt. is passed through a heating device with superheated steam slowly and without heating the oil above the b. p. of the oil being treated, the

mixt. is "steamed down" to a temp. somewhat above 100°, further cooled, and the filtering material is then sepd. from the oil. An app. is described. Cf. *C. A.* **21**, 3126.

Cracking hydrocarbon oil. GUSTAV EGLOFF (to Universal Oil Products Co.). U. S. 1,682,742, Sept. 4. Oil is passed through a heating coil into an expansion chamber which is connected with a dephlegmator; agitating fans are positioned in the upper portion of the vapor chamber; the dephlegmator is connected to a condenser, and the app. is maintained under superatm. pressure. Cf. *C. A.* **22**, 3772.

Apparatus for cracking hydrocarbon oils. ROBERT T. POLLOCK (to Universal Oil Products Co.). U. S. 1,683,801, Sept. 11. A dephlegmator is employed which is provided with partitions in a vertical cylindrical shell near the ends of the latter, forming upper and lower compartments and an intermediate compartment; a vapor inlet and vapor outlet communicate with the intermediate compartment and vertical tubes extend through the latter and connect the upper and lower compartments. The lower partition is provided with apertures through which the reflux condensate formed in the intermediate compartment can pass into the lower compartment. A cooling medium such as raw oil can be introduced into the upper compartment and can be withdrawn with the reflux condensate from the lower compartment. Other features of the app. are also described.

Apparatus for cracking oil. GUSTAV EGLOFF and WILLIAM R. HOWARD (to Universal Oil Products Co.). U. S. 1,683,766, Sept. 11. Pipes through which oil is passed and in which it is heated contain spiral agitating devices which are given a rotary movement by oil passing through the pipes. Each of these agitators is provided with a thrust bearing at the discharge end of the tube in which it is located.

Treating liquid residue from oil cracking processes. LYMAN C. HUFF (to Universal Oil Products Co.). U. S. 1,683,826, Sept. 11. Residual oil is withdrawn from a pressure cracking still while at a temp. above 200°, the pressure on it is lowered and it is introduced into an enlarged chamber from which evolved vapors are taken off and in which a body of the heated oil is maintained; the oil is continuously circulated in a closed cycle and regulated quantities of the hot oil are withdrawn from the cycle and used in furnaces as fuel.

Treating residue from oil-cracking operations. GUSTAV EGLOFF (to Universal Oil Products Co.). U. S. 1,683,767, Sept. 11. Residual oil contg. C in suspension which will not readily settle out on standing is centrifuged to ppt. the C particles after mixing the material with a distillate or other suitable hydrocarbon material of lower b. p. than the residual oil to lower the viscosity. The treatment is effected at a temp. below 95°.

Hydrocarbon still. WARREN K. LEWIS and NATHANIEL E. LOOMIS (to The Standard Oil Development Co.). Can. 283,093, Sept. 4, 1928. A still has two sets of connected coils for the stock, one set heated by radiant heat from a checker brickwork arch and the other by contact with products of combustion.

Refining hydrocarbon oils. SIJBREN TIJMSTRA (to Roxana Petroleum Corp.). U. S. 1,684,159, Sept. 11. Oils such as cracked oils are treated with a "doctor soln." and there is then added to the treated oil an aq. soln. of Na polysulfide or other suitable polysulfide capable of releasing free S and pptg. Pb from the oil.

Distilling oil from shales or coal. R. H. CROZIER. Brit. 283,639, Oct. 13, 1926. The material is heated at the upper end of a vertical retort to a high initial temp. (at least 400°) to volatilize pitch-like constituents and the heating of the semi-coke thus formed is maintained as the charge descends in the retort. A retort and vapor trap construction is described.

Treating oil shales and other bituminous materials. WILLIAM W. BLAISDELL. U. S. 1,684,007, Sept. 11. The material is preheated to a point somewhat below that at which the hydrocarbon vapors are formed and subsequently superheated to form such vapors in a sep. chamber of an app. which is described. The heat of the exhaust gases from the superheating chamber is used for the preheating after admixt. with atm. air to reduce their temp. The material is mechanically agitated in the preheating chamber and is passed to the superheating chamber without permitting escape of vapors.

Apparatus for treating oil. GEORGE C. KELLEY. Can. 283,501, Sept. 25, 1928. Oils having present various proportions of emulsions and water in suspension are treated by a preliminary heating in this app. to facilitate the sepn. of the water without increasing the emulsion, and the oils are confined in passages which are completely filled and so prevent foaming and ebullition during the time the oil receives its max. heat treatment.

Drying oil for electric transformers, etc. ALLGEMEINE ELEKTRICITÄTS-GES. (to International General Electric Co.). Brit. 283,592, Jan. 15, 1927. Oil for elec. trans-

formers or other insulating purposes is dried by contact with silica gel, a "bleaching earth" or other adsorbent of water, and is preferably maintained in contact with the adsorbent in the transformer or other app. during storage and transport.

Distributing pipe system, etc., for "routing" oil fractions or other materials undergoing fractional distillation. FRANCIS M. HESS. U. S. 1,683,778, Sept. 11.

Distillation apparatus for reclaiming oil from crank-case drainings, etc. ARNOLD L. HENNY. U. S. 1,684,270, Sept. 11.

Oil gas. CONSTANTIN CHILOWSKY. Can. 282,409, Aug. 14, 1928. Heavy oils are converted into non-condensable gaseous products with a minimum of liquid or condensable products, by atomizing the heavy oil, heating it to 700–1100° and passing the vapors over a catalyst heated to incandescence. The catalyzer is either a refractory, as Al_2O_3 or MgO, or metallic as Ni, Fe, non-rusting alloys and steel. Cf. *C. A.* 22, 1673.

Gasoline. EUGENE H. LESLIE and EDWIN M. BAKER. Can. 282,747, Aug. 28, 1928. Natural-gas gasoline soln. in absorption oil is introduced into the lower part of a distg. column above the lower end, hot vapors of the absorption oil, previously exhausted of gasoline, are introduced at a rate sufficient substantially to exhaust said soln. of its gasoline content, the exhausted absorption oil is heated to generate more hot vapors, substantially all the vapors leaving the top of the column are condensed except wild hydrocarbons, a part of the condensate is refluxed to said column above where the soln. enters, and a liquid gasoline product is collected and withdrawn from said column at a place above where said soln. enters and below where the refluxed condensate enters.

Fabric for "breather bags" of gasoline storage tanks, etc. CLARENCE M. CARSON (to Goodyear Tire & Rubber Co.). U. S. 1,683,759, Sept. 11. Fabric is treated with a gas-tight coating of glue-glycerol mixt. or other suitable proteinous material contg. a softening agent, the coating is partially dried, the fabric is stretched on a frame, treated with Na alum, CH_2O, $K_2Cr_2O_7$ or other suitable tanning soln. and the drying is then completed.

Increasing the power yield of benzine as a motor fuel. HANS BORGE. Norw. 44,899, Feb. 27, 1928. A few percent of refined sperm oil is added to the benzine.

Extraction of oils from pitch and asphalt. HERMANN SUIDA. Austrian 108,697, Sept. 15, 1927. The pitch, etc., is fed through a sloping conduit in a gas generator and is heated by the generator gases surrounding the conduit, the vapors evolved from the pitch being withdrawn at the top of the conduit. The residual coke falls out of the conduit on to the grate of the generator.

Sulfonic acids from mineral oils. G. S. PETROV. Russ. 428, Sept. 15, 1924. Sulfonic acids are extd. with an aq. soln. of EtOH, MeOH or Me_2CO and this ext. is used over again to obtain a higher concn. of sulfonic acids in the solvent.

Sulfonic acids from acid sludge from mineral or similar oils. G. S. PETROV. Russ. 1,447, Sept. 15, 1924. Acid sludge is dild. with water in equal parts and heated in an autoclave for 3–4 hrs. at 20 atm. The oil layer is then distd. and the fractions obtained are sulfonated as usual.

Sulfonic acids. G. S. PETROV. Russ. 460, Sept. 15, 1924. Acid-treated oil distillates, mineral oils, paraffin wax or ceresin is sepd. from sludge taken up with water and treated with gasoline, CS_2 or a similar water-insol. compd. to sep. the hydrocarbons.

Lubricant. ERNEST EDGINGTON. Can. 282,618, Aug. 21, 1928. A lubricant contains 1 pint of raw linseed oil, 2 oz. of beeswax and 2 teaspoonfuls of coloring matter.

23—CELLULOSE AND PAPER

CARLETON E. CURRAN

Progress in the field of cellulose and wood-pulp manufacture in the last six years. ERIK HAGGLUND. Inst. für Holzchemie der Akadamie Åbo (Finnland). *Z. angew. Chem.* 41, 6–14(1928). E. H.

Isolation and detection of cellulose in peat. K. HESS AND V. KOMAREVSKII. *Z. angew. Chem.* 41, 541–2(1928).—A method for the isolation of cellulose from peat has been developed and applied to a sample of peat from the environs of Moscow. The air-dry material (8–10% of moisture) is extd. with ether (loss, 6%) and then with an alc.-benzene (1:2) mixt. (loss [bitumen], 10%). The extd. material is next shaken with 1% NaOH soln. until no more colored substances are removed (loss, 49%), and

then subjected several times to the alternate action of a dil. (0.3-1%) soln. of ClO_2 and 2% Na_2SO_3 soln. (loss, 23%). The white, fibrous residue is dissolved in cuprammonium hydroxide and cellulose pptd., after addn. of alc. with acetic acid. The cellulose is washed with dil. acetic acid, water, alc., and, finally, ether. The purity of the sample is detd. by measuring the rotatory power in cuprammonium hydroxide soln. or the rotatory power of the acetate in chloroform or pyridine-acetone soln. The present sample contained 10% of cellulose, calcd. on the air-dry material. Whenever possible the purity of the cellulose obtained should be confirmed. The failure of Odén and Lindberg (*C. A.* **20**, 3342) and Marcusson (*C. A.* **21**, 1784) to do this renders the results open to criticism. B. C. A.

The study of cellulose and cellulose acetates by means of x-rays. JEAN J. TRILLAT. *Rev. gén. colloïdes* **6**, 57-68, 89-95(1928).—See *C. A.* **22**, 3043. E. H.

Cellulose acetate and cellulose acetate rayon. WILHELM A. DYES. *Chem.-Ztg.* **52**, 554-6, 574, 590-1, 630-1, 651-2(1928).—This series of articles is a general review of the economic and commercial sides of the development of cellulose acetate and cellulose acetate rayon. The various patents in this connection are discussed.
FREDERICK C. HAHN

Benzoylcellulose. KATSUMOTO ATSUKI AND KICHIRO SHIMOYAMA. *Kunstseide* **10**, 250(1928); cf. *C. A.* **21**, 4062.—Regenerated or normal cellulose is treated with 35% NaOH soln. and aged for 24 hrs. at ordinary temp. The resulting alkali cellulose is treated with BzCl and benzene in the following ratios: $C_6H_{10}O_5$: NaOH : BzCl = 1 : 4 : 10, and the mixt. is heated 1-2 hrs. at 50-60° on the water bath. The reaction product is poured into water, and washed several times with a large vol. of hot water. The benzoylcellulose obtained was $C_6H_8O_3(BzO)_2$ contg. about 66% benzoate group. The product from regenerated cellulose is sol. in $CHCl_3$ and acetone, giving solns. of very low viscosity. The films obtained from these solns. were very brittle. The product from normal cellulose is not clearly sol. in $CHCl_3$, its soln. having a very high viscosity, and its films being brittle. The brittleness with regenerated cellulose is attributed to the degraded state of the cellulose, while with the normal cellulose it is attributed to imperfect dispersion of the benzoylcellulose in the solvent. FREDERICK C. HAHN

X-ray investigation of cellulose nitrate. R. O. HERZOG AND S. VON NÁRAY-SZABÓ. *Z. physik. Chem.* **130**, 616-25(1927).—The Debye-Scherrer diagrams given by specimens of cellulose nitrate prepd. in different ways and of different N content all exhibit the same interference. It is therefore concluded that the various cellulose nitrates are in reality mixts. of cellulose trinitrate and unchanged cellulose. Consideration of the kinetics of the nitration and of nitration in general favors the theory of the exclusive production of cellulose trinitrate. The latter belongs to the quadratic system, the lattice consts. being a = 14.75, b = 7.88 and c = 10.30 A. U. The elementary cell contains 4 mols. B. C. A.

Micro-method for the determination of the nitrogen content of nitrocellulose. Fractionation of nitrocellulose by diffusion. D. KRÜGER. *Z. angew. Chem.* **41**, 407-8 (1928).—A sample of nitrocellulose (5-10 mg.) is moistened with a small quantity of alc. and hydrolyzed by heating at 50-60° with 5 cc. of 30% NaOH soln. and 0.5 cc. of 30% H_2O_2 soln. until a clear soln. is obtained. The nitrate is then reduced to NH_3 by addn. of 10 cc. of 30% NaOH soln. and 0.25 g. of Devarda's alloy, and the NH_3 is steam-distd. into $N/70$ HCl, the excess of acid being titrated with standard NaOH soln. If a soln. of nitrocellulose in an org. solvent is allowed partially to diffuse into the pure solvent, it is found that a sepn. into 2 fractions of different phys. behavior and of different N content has taken place. B. C. A.

The chemistry and physics of artificial silk. R. O. HERZOG. Kaiser Wilhelm-Inst. für Faserstoffchemie. *Z. angew. Chem.* **41**, 531-6(1928). E. H.

Treating viscose rayon. LAMBECK. *Kunstseide* **10**, 115-6(1928).—A discussion is given of the essential features of the spinning-pot and of the spool methods for the manuf. of rayon. It is pointed out that plants using the spool method may offset some of the disadvantages of this process by introducing machines for twisting and reeling the thread while still wet. FREDERICK C. HAHN

Poisonous gases in a viscose rayon plant and their removal. JOHANN EGGERT. *Chem.-Ztg.* **52**, 505-6(1928).—A general discussion of the question of removing H_2S and Cl from the spinning and the bleaching app., resp. The drawbacks of various construction materials used for equipment for removing gases are discussed from the standpoints of corrosion and cost. A *corrosion-resisting material*, "Haveg," is especially recommended as a construction material in the foregoing cases. FREDERICK C. HAHN

The properties of silk coagulates made by pouring colloidal silk solutions into concentrated tannin solutions. P. P. VON WEIMARN. *Kolloid-Z.* **45**, 39-42(1928).—

The coagula made by pouring solns. of silk in aq. salt solns. (NaI) into 30 to 40% tannin soln. can be drawn out into glistening threads, but on drying they become very brittle. Most of the tannin can be washed out by prolonged boiling in water but the resulting threads are not stable. By washing in water, then in hot 9% soap soln. and finally in water, the tannin can be removed completely and stable threads produced. F. L. BROWNE

The preparation of stable threads from silk coagulates. P. P. VON VEIMARN. *Kolloid-Z.* **45**, 36–9(1928).—Glistening silk threads were made artificially by allowing very concd., viscous solns. of silk in aq. salt solns. (NaI or NaCNS) to flow in a fine stream into concd. solns. of coagulating salts (Na citrate or Na K tartrate) and then washing out the salts in boiling water. Some of the threads so prepd. remained unchanged after $1^1/_2$ yrs.; others became brittle. F. L. BROWNE

Chemistry and the press. ALBERT RANC. *Chimie et industrie* Special No., 101–8 (April, 1928).—An address bringing out the part played by chemistry in the production of modern newspapers. A. PAPINEAU-COUTURE

The use of tallöl in the alkali wash of petroleum distillates (DITTLER) 22. Tanning products derived from the manufacture of wood cellulose (ESCOURROU) 29. Composition and structure of the cell wall of wood (RITTER) 11D. Dispersoidological investigations. XVIII. The structure of cellulose fibers (VEIMARN, *et al.*) 2. Ac_2O [in acetylating cellulose] (Brit. pat. 283,781) 10. Boiling down liquids evolving volatile constituents (Ger. pat. 451,973) 13.

Cellulose. HERMAN BUBEC (to I. G. Farbenind. A.-G.). Can. 283,412, Sept. 18, 1928. Cellulose of high degree of purity is manufd. by first mercerizing the cellulose, and then treating with a NaOH soln. of 8 to 9% and finally washing the product free from alkali.

Cellulose. ARTHUR FRANZ (to I. G. Farbenind. A.-G.). Can. 283,573, Sept. 25, 1928. Cellulose is produced from vegetable material by treatment at temp. below 80° with a concd. soln. of a chlorate, more readily sol. in H_2O than $KClO_3$, and comprising spent lye of a previous operation in mixt. with a moderate quantity of HCl.

Cellulose product. OTTO C. STRICKER. Can. 282,455, Aug. 14, 1928. Cellulose is produced by the decompn. of vegetable fibers by the use of boiling solns. (lyes) consisting of a salt-like compd. of at least one sol. hydroxy compd. of the isocyclic series (phenols, cyclohexenol, hydrogenated phenols naphthols, hydrogenated naphthols, methylcyclohexanol, polyphenols, hydroxysulfones, sulfonic or carboxylic acids of above substances, functional derivs. of phenols or its homologs), with a metal (alkali group, certain of the alk. earth metals and metals of the magnesium group are suitable) which replaces at least one H atom of the hydroxy compd.

Manufacture of cellulose. AKTIESELSKAPET RAOUL PICTET & F. THARALDSEN. Norw. 43,950, April 19, 1927. An addn. to Norw. 42,934 (*C. A.* **21**, 2188) regarding the manuf. of cellulose by treating cellulose-contg. materials with an aq. soln. of SO_2. The boiling process is carried out under a pressure of at least 8 atm. During one or more periods of the boiling the temp. is kept partly below, partly above 110°.

Boiling cellulose. EINAR MORTERUD. Norw. 44,543, Oct. 24, 1927. When a cooking is finished, before the digester is emptied, a part of the hot liquid is blown over into a second digester filled with raw chips, the discharged amt. of hot liquor in the first digester being immediately replaced by an equal amt. of cold used liquid of nearly the same concn.

Heating the liquid in cellulose digesters. AKTIESELSKAPET RAOUL PICTET & F. THARALDSEN. Norw. 44,363, Aug. 29, 1927. A part of the liquid is taken out from the filled digester and heated and eventually evapd. in a sep. heating app. The mixt. of gas and steam is blown directly into the same or another digester. The evapd. liquid may also be returned into the same or another digester.

Letting off the pressure from cellulose digesters. EINAR MORTERUD. Norw. 44,111, June 7, 1927. Mech. features of the procedure intended to reduce the time required for letting off the steam pressure from the boilers while the heat of the escaping steam is utilized as completely as possible.

Treating cellulose and similar materials with chlorine. H. HJORTH. Norw. 44,087, May 30, 1927. Cellulose and similar materials in the form of a half solid mass contg. about 30% of dry matter are in thin layers subjected to the action of Cl gas partly under free fall through the Cl gas in a cylindrical (vertical) app. with rotary axle, under reduced pressure. The Cl gas is introduced at a considerable distance above the outlet for the treated materials in the bottom of the app.

Composition for treating cellulose sheets. CHARLES R. FELIX. Can. 282,965, Sept. 4, 1928. The compn. specified contains 72 g. Na_2CO_3, 1 qt. of liquid Na silicate soln. 40° Bé., 46 g. Na tungstate and 2 gallons of water. Cf. *C. A.* **21,** 3743.

Cellulose ester. HEINRICH HEINMANN and ALFONS BAYERL (to I. G. Farbenind. A.-G.). Can. 283,266, Sept. 11, 1928. Cotton to be esterified is first treated with formic acid of 85% strength. Cf. *C. A.* **21,** 3742; **22,** 164.

Cellulose ether. LEON LILIENFELD. U. S. 1,683,831, Sept. 11. Low-alkali-content and low-water-content alkali cellulose contg. not over 50 parts each of alkali and water per 100 parts cellulose is treated with etherifying agents such as alkyl sulfates or halides and caustic alkalies and etherifying agents are allowed to act on the intermediate formed. The products obtained are suitable for making films, etc.

Cellulose ethers and alkali cellulose. LEON LILIENFELD. U. S. 1,683,681, Sept. 11. An alkali cellulose of low water content suitable for alkylation or aralkylation is prepd. by treating an alkali cellulose obtained by evapg. water from an alkali cellulose contg. more water than alkali, with solid caustic alkalies. U. S. 1,683,682 specifies drying the material at a temp. below 18°, in prepg. alkali celluloses of low water content by drying watery alkali celluloses.

Cellulose nitroacetates and similar esters. I. G. FARBENIND. A.-G. Brit. 283,595, Jan. 15, 1927. Manuf. of nitric acid-aliphatic acid esters of cellulose is so conducted that during the esterifying process the cellulosic material is exposed in such a form to the action of the HNO_3 that the nitration proceeds of itself rapidly and uniformly. *E. g.*, cotton may be first partly esterified by Ac_2O in the presence of H_2SO_4 and HOAc, with subsequent addn. of HNO_3. Various other alternative procedures of similar character are also described.

Celluloid. EMIL G. JOHNSON. Can. 283,499, Sept. 25, 1928. Celluloid is rendered pliable for molding by suspending it in an air-tight chamber and subjecting it to the fumes of acetone or other suitable solvent, to soften said material, then molding the material and subjecting it to oven heat.

Sulfate cellulose boiling liquid. TORBJÖRN N. M. MOLIN. Norw. 44,412, Sept. 26, 1927. Dil. boiling liquid, soda soln. or water after addn. of CaO is carried continuously through a series (2 or more) of dissolving vessels where the fused mass from the soda furnaces is introduced in continuous current. Before entering into this process the boiling liquid may be used for impregnating the raw chips, a treatment which has been found to further the economy of the sulfate cellulose process.

Recovery of acetic acid from cellulose acetate solutions. SOCIETE CHIMIQUE DES USINES DU RHÔNE. Ger. 462,994, June 28, 1928. See Brit. 266,684 (*C. A.* **22,** 597).

Concentrated acetic acid from solutions of cellulose acetate in acetic acid. VEREIN FÜR CHEM. IND. A.-G. (Eduard Löw, inventor). Ger. 463,871, July 19, 1928. The AcOH is driven out with a current of steam or dil. AcOH vapors at ordinary or reduced pressure. Cf. *C. A.* **22,** 1473.

Regeneration and utilization of sulfite cellulose waste liquor. WILHELM MICHAEL AND ALBERT PALM (to I. G. Farbenind. A.-G.). Can. 283,415, Sept. 18, 1928. In the process of producing cellulose by means of H_2SO_3 and NH_3, free H_2SO_3 is blown from the waste liquor, NH_3 and a catalytic material are added, the liquor is heated in a closed vessel to a temp. above 180°, C is filtered off, H_2SO_4 and $(CO_2H)_2$ are pptd. and filtered off, and the liquor is used again in a following pulping operation after introducing H_2SO_3. After repetition of these operations NH_4 salts of org. acids are recovered from the filter and liquor finally obtained.

Regulating flow of viscose. EZIO PENSOTTI. Austrian 108,692, Sept. 15, 1927. A pump for use in manufg. artificial silk from viscose is described.

Artificial silk. F. J. GAHLERT. Brit. 283,752, Feb. 10, 1927. See U. S. 1,666,090 (*C. A.* **22,** 2056).

Artificial silk. NORDDEUTSCHE VERWALTUNGS GES. Brit. 283,481, Jan. 10, 1927. To reduce the denier number of freshly prepd. artificial threads, the threads as produced by suitably modifying the coagulating process or by a sep. treatment to which the freshly spun threads are subjected, are stretched mechanically without being subjected to sliding friction, as by the use of a suitable set of rollers, and are dried under tension. The use of swelling agents and numerous other details of procedure are described.

Fine threads of viscose silk. LAMBERTUS ALEXANDER VAN BERGEN. Dutch 18,391, July 16, 1928. Addn. of 1/2 to 2% of Zn or Al sulfate to the acid spinning bath (sulfuric acid + sulfate) allows spinning of very thin threads (6 and 3 deniers) without increase in acidity (4 to 5% acid).

Apparatus for producing artificial silk filaments by the stretch-spinning cupram-

monia process. J. P. Bemberg A.-G. Brit. 283,923, Jan. 20, 1927. Threads during their treatment with acid in channeled devices or troughs are led through guides (which may be formed of acid-resisting steel) adjustably positioned within the troughs, by which the grain of structure of the finished threads can be controlled.

Feeding wood chips to a digester. George H. Tomlinson. Can. 282,665, Aug. 21, 1928. The hot liquor blown from a digester with a cooked charge is sepd. from the charge and redirected to the top of the digester and simultaneously fed thereinto with the wood chips for a second charge, thereby soaking and preheating and closely packing the wood chips in the digester.

Agitating and washing fibrous pulp in a series of separate baths. Charles A. Johnson (to Brown Co.). U. S. 1,683,782, Sept. 11. Mech. features.

Sulfite pulp. George H. Tomlinson. Can. 282,834, Aug. 28, 1928. A charge of wood chips is preheated in a digester to a temp. of approx. 100° by means of hot liquor discharged with the cooked pulp in a previous digesting operation, a charge of cooking acid is preheated in another container to a temp. approx. 100° by means of hot gases obtained as the result of a previous digesting operation, the two preheated materials are brought together in a digester in such a manner as to maintain approx. the same temp. between the chips and cooking acid, and then steam is introduced into the mass to complete the cooking operation. Cf. *C. A.* **22,** 1041.

Apparatus for manufacture of sulfite pulp. Lemuel B. Decker. Can. 283,384, Sept. 18, 1928.

Recovery of waste gases in sulfite pulp manufacture. George A. Richter (to Brown Co.). U. S. 1,683,628, Sept. 11. In recovering SO_2 from hot blow-pit vapors and gases, the latter are conducted through spiral brick or other suitable confined inert interstitial material in counter-current flow to cold acidulated water, so that vapors are condensed and the gases are cooled; the cooled gases are then led through another mass of interstitial material in contact with water to effect absorption of SO_2; the acidulated water for the first-mentioned treatment is supplied from the second stage of the process and the SO_2 liberated in the first stage may be reused in the pulp manuf.

Sulfite liquor. George A. Richter (to Brown Co.). Can. 283,024, Sept. 4, 1928. A cooking liquor for the production of pulp comprises H_2SO_3 soln. contg. $(NH_4)_2SO_4$ and sodium salts.

Regenerating spent sulfate liquors. Alfred H. White (to J. E. Alexander and E. G. Goodell, trustees). Can. 283,128, Sept. 4, 1928. The spent liquors obtained by the sulfate process for the manuf. of pulp are regenerated by concn. until the effective heating value of the liquor is more than sufficient to calcine a wt. of $CaCO_3$ equal to the wt. of the sol. inorg. salts in the liquor, burning the concd. liquor in air and in the presence of $CaCO_3$, whereby the $CaCO_3$ is converted into CaO, intimately mixing the CaO with the non-combustible residue of the liquor to form a solid product comprising largely CaO, alkali carbonates and sulfates, mixing said solid products while still above a red heat with carbonaceous matter sufficient to reduce the sulfates to sulfides, largely effecting such reduction at a temp. above 1100° F., and leaching the reduced mass with H_2O to dissolve alk. salts.

Tanning agent from sulfite cellulose waste liquor. Carl Hüttenes and Carl Peter Hüttenes. Ger. 451,913, Nov. 4, 1927. One cu. m. of sulfite cellulose liquor of 6.5° Bé. is neutralized with 7 kg. of CaO and heated to boiling. Twelve kg. of cryst. Na_2S is added and boiled for 45 min. The Na_2S added amounts to 10–12% of the dry content of the liquor. The resultant product is filtered and concd. to 24° Bé. The lime is pptd. with 1.55 kg. of 96% H_2SO_4 dild. with an equal quantity of H_2O and 9.6 kg. $Al_2(SO_4)_3$ dissolved in the same quantity of water. The above quantities of reagents are added to 100 l. of the filtrate. The lime ppts. as sulfate and is filtered off. The filtrate is further concd. to 30° Bé. It is then dried to a yellowish powder. Na_2SO_4, $NaHSO_4$, $Cr_2(SO_4)_3$ or $(NH_4)_2SO_4$ may replace the $Al_2(SO_4)_3$. In place of 12 kg. of Na_2S used above, 8 kg. of Na_2S and 4 kg. of NaOH may be used.

Derivative from ligninsulfonic acid. Anthony J. Hailwood (to British Dyestuffs Corp., Ltd.). Can. 282,677, Aug. 21, 1928. A new deriv. of ligninsulfonic acid (sulfite cellulose pitch) is obtained by treating at 110–120° under pressure with NH_3 soln. The new product is particularly suitable for addn. to dispersed *dye pastes* which are to be dried to powder form. It also finds application as *tanning agents*.

Paper pulp. B. Dorner (to Euromerican Cellulose Products Corp.). Brit. 283,851, Jan. 17, 1927. Materials such as corn stalks, straw, flax, esparto grass and the like are finely shredded, water-sol. constituents are extd. with a stream of hot or cold water (which may require 4–5 days). The liquor thus obtained may be evapd. to use in

stock feed or may be fermented to *produce alc.* The leached material is beaten and boiled in NaOH soln. at ordinary or increased pressure, using just enough alkali to react with the silica present. Pentosans may be recovered from the liquor thus produced. The partially cooked material is then further digested with NaOH and washed and bleached in the usual manner.

Paper pulp. EXECUTORS OF BARON CABLE, G. C. GODFREY, E. C. BENTHALL, E. S. TARLTON and H. F. WHEELER (TRADING AS BIRD & CO.) and E. SPENCER. Brit. 283,910, Jan. 20, 1927. In a semi-continuous process for producing cellulose or paper-pulp from material such as bamboo, grasses, wood or reeds in a cascade digestion system in a closed ring in which each digester is charged in turn (the stock in any one being then subjected to a series of treatments with caustic liquor or mixed caustic and sulfide or sulfite liquors, at successively increasing pressures and concns., followed by leaching and washing), the digesting liquor after use in any one digester is passed to the digester next-but-one lower in the cycle of operative sequence. The liquor may be blown over by steam pressure and made up with wash water to the desired vol. and concn. An app. is described. Brit. 283,911 specifies passing steam from a pulp digester in which the process is complete into another digester which is being or has been freshly charged to heat the charge and any assocd. liquor. An app. is described.

Beater for paper pulp. LORENZO M. AVENSON. U. S. 1,683,597, Sept. 11. **Treating paper pulp and other fibrous masses.** K. SVEEN. Norw. 44,095, June 7, 1927. In order to obtain a better agglomeration of the particles of paper mass and in order to further the sepn. from the liquid, relatively small quantities of dissolved or emulsified substances such as gelatin, glue, casein, rubber latex, soap, etc. are added to the suspension which already contains $Al_2(SO_4)_3$ or similar colloid-coagulating substances. A good working addn. is 0.1% of the total dry matter of glue in the form of a soln. which has been stored at 5–15° for a couple of days. It may be favorable to apply the glue together with some substance having the power of pptg. the glue colloid, for instance sulfite cellulose waste liquor.

Paper filter packs. HENRY S. HELE-SHAW and JOSEPH A. PICKARD. Can. 281,702, July 17, 1928. Paper filter packs are prepd. for edge filtration by treating the paper with any of the following substances, nitrocellulose, acetylcellulose, rubber, chlorinated rubber, celluloid, casein, cellulose esters, synthetic or natural resin, paraffin, hardened gelatin, asphaltum, bakelite and similar formaldehyde condensation products.

Transparent paper. O. KLOTZ. Brit. 283,751, Feb. 7, 1927. Paper such as pergamyn or parchment paper is rendered transparent and suitable for bags for edible articles by coating on one or both sides with gelatin soln. and drying.

Water-proofed paper. JAMES REID. Can. 282,444, Aug. 14, 1928. Close-grained paper is water-proofed without destroying its flexibility and strength by quickly passing the paper through a bath of mineral rubber (a bituminous product) 100 parts, scale wax 10 parts and Montan wax 2 parts, the mixt. being heated above 350° F. (say 450° F.), and quickly stripping the superfluous coating and lowering the temp. of the finished product. Cf. *C. A.* **22**, 3530.

De-inking solution. WILLIAM LEWIS. Can. 283,130, Sept. 4, 1928. A de-inking soln. for paper stock contains Na or K silicate, NaOH, pearline and water.

Ornamentation of paper surface. MICHEL RUDIE (to W. V. Dawson, Ltd.). Can. 283,047, Sept. 4, 1928. The surface of paper is ornamented by applying dyes of chemically repellent nature in contiguous relation and enabling the dyes to build up a border of heightened color outlining the division between the color areas and applying to said color areas a self-crystallizing compd. of metallic sulfates and preventing the crystn. at certain portions of the surface by previous chem. treatment.

24—EXPLOSIVES AND EXPLOSIONS

CHARLES E. MUNROE

Max von Duttenhofer. H. BRUNSWIG. *Z. ges. Schiess-Sprengstoffw.* **23**, 257–60 (1928).—A review of the contributions of D. to the *smokeless powder* industry, commemorating the 25th anniversary of his death. C. G. STORM

Further regarding liquid air explosives. C. BUNGE. *Z. ges. Schiess-Sprengstoffw.* **23**, 193–4(1928); cf. *C. A.* **22**, 2057, 3047.—Controversial, relative to dangers of use. C. G. STORM

The question of safety in use of liquid air explosives. F. W. WEDDING. *Z. ges. Schiess-Sprengstoffw.* **23**, 159–60(1928).—Prussian statistics are cited to show that

liquid air explosives used in mining are in no respect safer to use than the usual solid explosives. C. G. Storm

The new Hungarian Government powder factory in Füzíő. Franz Langenscheidt. *Z. ges. Schiess-Sprengstoffw.* **23**, 157–8(1928).—This factory, completed in May, 1927, comprises sep. units for the manuf. of *nitroglycerin, nitrocellulose,* military *smokeless powder* and *TNT*. The power plant is constructed underground in dolomite rock, so as to be bomb-proof and safe from air attack. Nitroglycerin is manufd. by the improved Nathan process. American type nitrators are used in the nitrocellulose plant, to obtain uniform nitration and freedom from nitrator fires. After centrifuging to remove the spent acid, the nitrocellulose is again covered with cooled H_2SO_4 in order to obtain more complete recovery of the HNO_3. TNT is made setting by the 2-stage nitration process, and recrystd. from H_2SO_4, yielding a product with setting of 80°, which may be increased to 80.3° by recrystn. from an org. solvent. C. G. S.

Blasting with liquid oxygen. M. Grunow. *Bautechnik* **6**, 412–7(1928).—Operating details are given. E. M. Symmes

The preparation of mixed acids (with particular reference to the explosives industry). von Bezold. *Z. ges. Schiess-Sprengstoffw.* **23**, 190–3(1928).—The mixing of strong HNO_3 and H_2SO_4 or oleum in various types of app. is described. Of special interest is an app. for this purpose in which neither compressed air nor mech. stirrers are used for mixing. The HNO_3 and H_2SO_4 are allowed to flow from weighing or measuring tanks, together with a stream of previously mixed acid, into a header terminating in a coil of "Azidur" immersed in a cooling tank. The uniform mixt. flows from the coil into a receiving tank, is pumped to an elevated storage tank from which it can flow through a cooler back to the mixing header. The process may be made continuous, and a capacity of about 5 tons per hr. may be obtained. C. G. S.

Miedziankit and its manufacture at Langelsheim am Harz. M. Winter. *Kali* **22**, 161–4, 181–4, 201–5, 226–9(1928).—This is a review of the history and manuf. of "Miedziankit," a chlorate explosive contg. $KClO_3$ 87%, *petroleum* 10% and beech wood flour 3%. This is stronger than saltpeter blasting powder but weaker than dynamite. Details are given of plant and building construction, power, water and steam supply and fire and lightning protection. Safety measures include mat surface window glass and tanks outside every door for quenching blazing clothing. The $KClO_3$, contg. less than 0.15% $KBrO_3$ and 0.05% H_2O, is dried, ground in a Gloria or a Matador mill, mixed with wood meal and cartridged. It is then satd. with a petroleum distillate (I) by dipping 3 times into pans contg. $^1/_3$ the total quantity required. I must have a flash point above 30° and a free acid content less than 0.075% (as H_2SO_4) and is freed from water by filtering through CaC_2. Paul J. Culhane

Apparatus for determining the ignition and explosion points of explosives. M. Kostevitch. *Z. ges. Schiess-Sprengstoffw.* **23**, 156–7(1928).—Two types of app. are illustrated and described. One for the detn. of the ignition temp. of such materials as *smokeless powders* is entirely of glass, 0.1 g. of sample being sealed in a 3.5-cc. glass bulb suspended near the bottom of a large test tube within a second larger tube, the latter being immersed in the liquid-heating bath. Thermometers are placed in the inner tube and in the bath. The glass app. aids in detecting the first signs of ignition. The app. for detn. of explosion point of *high explosives* is constructed of metal, the electrically heated bath being of Wood's metal. The sample is contained in a sealed glass bulb of 0.5-cc. capacity suspended in a metal tube within the bath. Detns. of the ignition temp. of Russian and German nitrocellulose smokeless powders 16 years old showed these powders to be in excellent condition and superior to other types of powders. C. G. Storm

Ignition temperature of aromatic nitro compounds. S. Micewicz and K. Majkowski. Officers' Engineering School (Warsaw.) *Przemysl Chem.* **12**, 197–214 (1928).—Detns. of ignition temps. of certain explosives according to the methods recommended by official specifications do not give a true value because the temp. of the bath in which the explosive is heated deviates widely from the temp. of that substance. Strong exothermic processes of decompn. were noticed in these investigations. These result in a higher temp. of the explosive than is recorded by the heating bath so that at a certain stage the flow of heat from the bath to the explosive reverses its direction. To avoid such complications app. must be so designed that the temp. will be measured right in the explosive material itself and not in the surrounding bath so that the smallest variations of temp. may be recorded. To make this possible the thermometer must have very low heat capacity. M. and M. used for the thermometer a Pt-Ir resistance wire 0.05 mm. diam. and 10–16 mm. long, soldered with Ag to Cu leads 1–1.5 sq. mm. and 25–30 cm. long. After igniting it the Pt-Ir wire would be

immersed in 1.2–1.5 g. of the molten sample held in a test tube 15 mm. diam. and 16 cm. long. This test tube would then be put in a bath of molten Wood's metal or oil, the temp. of which is measured with a Hg thermometer. For measuring changes of resistance of the Pt-Ir wire a modified form of Wheatstone's bridge was used. Each new piece of wire on soldering it with Ag had to be calibrated. With trinitrotoluene (I) and picric acid (II) violent variations of temp. took place after it became hotter than the bath, *i. e.*, a few seconds before the explosion. This was not observed with tetranitromethylaniline (III). I and II (but not III) reach a max. temp. during heating which is followed by a lowering of temp. and then the detonation. Because of the rapid and violent variation this temp. was not established. Detns. were made with the bath being heated at the rate of 5°/min. and 10° or 20°/min. The method of "sudden heating" which consists of suddenly immersing the test tube with the sample in a bath preheated to the right temp. gave consistent and good results because side reactions taking place during gradual heating of the explosive are then largely avoided. It is most important to establish a definite temp. to which the bath is to be preheated before the sample is plunged into it. The following results were obtained with this method: I 312–318°; II 337–346°; III 208–226°, depending on the temp. of the bath into which the sample is plunged. A. C. Zachlin

The use of firing machines and firing switches for high voltage current in mine blasting. Heyer. *Z. ges. Schiess-Sprengstoffw.* **23**, 185–9, 233–4(1928).—A description of various types of app. used for firing *mining explosives*, and methods of connecting shots. C. G. Storm

The electric firing of blasts with high voltage current in quarries. W. Borchers. *Z. ges. Schiess-Sprengstoffw.* **23**, 189–90(1928).—A discussion of safety precautions, etc. C. G. Storm

The propagation of combustion in mixtures of hydrocarbons and air. R. Duchêne. *Chimie et industrie* Special No., 279–80(April, 1928).—See *C. A.* **22**, 1476. A. P.-C.

Laws governing the combustion of colloidal powders. Henri Muraour. *Compt. rend.* **187**, 374–5(1928); cf. *C. A.* **22**, 1042.—It has been found that the area, $\int pdt$, expressed in kg. per sq. cm. per sec., is a characteristic of a burning powder which is practically independent of the cooling effect of the walls of the containing vessel, and of the density of loading. Assuming that the presence of another powder having a higher rate of combustion and a higher explosion temp. would accelerate the combustion of one of low rate of combustion and low explosion temp., tests were made, in a Vieille bomb, of the last-mentioned powder, alone, and of the same wts. of charge of it in admixt. with 50–75% of a powder having a very much higher rate of combustion and double the explosion temp., but the results for all were identical within the errors of expt. M. concludes that the total area, $\int pdt$, characteristic of a given powder, is not modified when there is substituted for a part of this powder a powder of different quickness, no matter what the temp. of the gas from the added powder may be, and he holds the simplest explanation to be that because of its continuous emission the gaseous mass which surrounds the powder grains cannot come into contact with the surface of the powder. This is therefore carried to its decompn. temp only by the layer of gas in contact with it and which it is itself emitting. Hence the gaseous mass which surrounds the grains of burning powder acts solely by its pressure and not by its temp. Charles E. Munroe

The duration and length of explosion flame from different explosives. H. Kast and H. Selle. *Z. ges. Schiess-Sprengstoffw.* **23**, 153–6(1928).—The usual methods were employed for obtaining photographs on both rotating and stationary films of the flame effect from the explosion of *TNT*, *Tetryl*, *guhr dynamite* and a no. of different types of German *coal-mining explosives*. With the latter the duration of flame was 0.0003 to 0.00035 sec. and the length 11 to 85 cm. For TNT, tetryl and guhr dynamite, resp., the duration was 0.020, 0.011 and 0.0045 sec., and the length 150, 150 and 85 cm. The coal-mining explosives showed only a primary flame, whereas TNT in particular showed 3 stages of flame, a primary flame of about 0.001 sec. duration, a weak secondary flame of 0.003 sec., and an after flame of 0.015 sec. The latter is caused by the burning of combustible gases on mixing with the air. C. G. S.

The study of moving flames. Wm. Payman. Safety in Mines Research station, Buxton. *J. Chem. Soc.* **1928**, 1738–40.—A brief description of the "flame-speed" and "wave speed" cameras used for photographing the motion of flame in gaseous mixts. The former can be used only for photographing slowly moving and feebly actinic flames, while the latter can be used for all kinds of flames and shock-waves, and also in an undarkened room. In both, the photographic film is stretched around a revolving

drum, provided with a device for synchronizing the time of exposure with the moment of passage of the flame across the field of view. In the flame-speed camera a diverging beam from a powerful mirror-arc lamp passes through a small orifice (giving a point source), and through the explosion-tube to the camera drum. By placing a plano-convex condenser (20 cm. diam.) between the explosion-vessel and the camera film, a reduction of about $^1/_4$ the actual size is obtained, eliminating the use of too wide a film for photographing the entire explosion. In the wave-speed camera (cf. *C. A.* **20,** 2074; **21,** 322, for a complete description) a beam from a mirror-arc lamp, so reflected by a concave mirror to be convergent, is focussed on the camera lens, a diaphragm on which serves to sep. refracted from non-refracted light. By properly arranging the 2 cameras a direct photograph is obtained of the flame the same in size as the refraction photograph, providing the flame is sufficiently actinic. J. BALOZIAN

Striated photographic records of explosion waves. II. An explanation of the striae. COLIN CAMPBELL AND ARTHUR C. FINCH *J. Chem. Soc.* **1928,** 2094–106; cf. *C. A.* **21,** 3271.—Several theories have been advanced to account for the striae observed in photographs taken with a moving-film camera, of explosions waves produced in gaseous mixts., especially those of CO and O_2, with or without addns. of small quantities of H. These theories have been investigated experimentally and it is concluded that the theory of E. F. Grieg, *viz.*, that the striae are due to the flame traveling along a helical path in the tube best accounts for all the facts observed. C. E. M.

Fatal accident at Billingham. ANON. *Chem. Age* (London) **19,** 237(1928).—An explosion, by which two men were killed, occurred Sept. 9, 1928 at the CO gas holders of the Synthetic Ammonia and Nitrates branch of the Imperial Chem. Industries. The men killed were on a platform some 30 ft. high working at a repair job when the gas escaped from a holder mixed with air and took fire from an unknown source. The gas mains were provided with isolation valves held closed against the pressure of the gas by oil pressure on the opposite side of the piston and by some undetd. means one of these valves is believed to have been released. CHARLES E. MUNROE

Detonation explosive. THORVALD LINDEMAN and MAGNE HAFSTAD. Norw. 44,012, May 9, 1927. A finely pulverized alloy contg. metallic Ce together with another strongly electropositive metal such as Mg, Al or both is mixed with an oxidizing substance, for instance $KClO_3$, NH_4NO_3, $KMnO_4$, $KCrO_4$, etc. The content of Ce of the alloy may be replaced in full or in part by other metals belonging to the group of the rare earth metals.

Time fuses for explosives. CURTIS'S & HARVEY, LTD., AND A. J. GRIMWOOD. Brit. 283,741, Jan. 21, 1927. A black powder used for loading time fuses is made by use of "cuprene" (a condensation product of C_2H_2 described in Brit. 146,258 (*C. A.* **14,** 3533)) instead of all or part of the charcoal usually employed. This powder is firmly compressed in grooves of rings which may be made of brass or of Al alloy with brass-lined grooves.

25—DYES AND TEXTILE CHEMISTRY

L. A. OLNEY

The Sandoz chemical works, Basle, Switzerland. CHAS. E. MULLIN. *Am. Dyestuff Rept.* **17,** 594–5(1928).—Special reference is made to the production of immunized cotton at this plant. L. W. RIGGS

The relation between laboratory and bulk production. H. H. HODGSON. *J. Soc. Dyers Colourists* **44,** 275–6(1928). L. W. RIGGS

Colors in commerce. EDWIN W. ELY. U. S. Bureau of Standards. *Am. Dyestuff Rept.* **17,** 572(1928).—The subject is discussed from the points of view of the manufacturer, the distributor and the consumer. The situation is summed up as follows: Overdiversification is wasteful. Overstandardization stultifies and restricts. Simplification, intelligently and moderately applied, offers a happy medium between these 2 extremes. L. W. RIGGS

Constitution of colors. GEORGE V. HEYL. *Paint, Oil Chem. Rev.* **86,** No. 8, 8–11, 15(1928).—The constitution of lithol red and the dyes generally grouped under the name of lithols are reviewed. Many lac-dyes and org. pigments are studied with respect to the effect of their constitution on shade and phys. properties. True *lithols* are differentiated from *pseudo-lithols* and red org. pigments. The lake reds are classified and reviewed with reference to prepn. and color groups. R. J. MOORE

Brief review of the development of anthraquinone dyes. ROBERT E. SCHMIDT. *Z. angew. Chem.* 41, 41–6, 80–5(1928). E. H.

Some chemical and physical properties of anthracene blue. RAYMOND L. DREW. *Am. Dyestuff Rept.* 17, 591(1928).—The sol. Anthracene Blues are described in a general way, and Anthracene Blue WR and WG are compared as to their dyeing properties. L. W. RIGGS

Auxanin B. PAUL RABE. *Melliand Textilber.* 9, 665(1928).—By working silk, rayon or cotton fabrics dyed with basic colors on Katanol-Sb mordant in a bath made of 2–5% Auxanin B (on wt. of goods) and a little NaCl and HOAc for 45 min. at 25–30°, a marked increase in light-fastness results. E. R. CLARK

Manufacture of para red. D. DAVIDSON. *Paint, Oil Chem. Rev.* 86, No. 1, 18D–20(1928).—The uses and manuf. of para red are reviewed. Detailed formulas and procedure for prepg. extra light, bluish light and dark para reds are given. R. J. MOORE

Condensation of badan extract with *p*-nitrosodimethylaniline. S. N. GODNEV. *J. Chem. Ind.* (Moscow) 5, 78–9(1928); cf. *C. A.* 22, 3302.—Dyestuffs can be obtained by condensation of badan ext. with aromatic compds. Thus, when 10 pts. (by weight) of dry badan ext., 7 pts. *p*-nitrosodimethylaniline-HCl and 200 pts. CH_3OH or C_2H_5OH are heated on a water bath the mixt. acquires first a yellow-brown, then a black-green and finally a black color. After 8–10 hrs. of heating, the alc. is distd. off and the resine-like residue is dried in a vacuum oven below 50° till it becomes solid. To sep. the insol. substances the solid is treated with 50 times its weight of hot water, filtered and the filtrate is evapd. to dryness on a water bath. The yield of the sol. dyestuff is 8%. The dyestuff is sol. in cold water, CH_3OH and C_2H_5OH. Dil. acids such as CH_3COOH, $(COOH)_2$, HCl and H_2SO_4 dissolve it with a red-brown color, concd. solns. being black. C_6H_6 and ether do not dissolve it. 0.5 *N* NaOH or Na_2CO_3 ppts. the dyestuff from its aq. solns. Tests for the presence of tannins show negative results, and this indicates that the dyestuff was formed at the expense of tannins and *p*-nitrosodimethylaniline. By direct dyeing of wool and cotton black, brown and dark gray colors are obtained. Acid dyeing of wool yields dark brown colors, whereas alk. dyeing of cotton gives gray-blue colors. If the dyestuff soln. is used in the presence of reducing agents, wool is dyed in brown and cotton in gray-blue. Attempts to condense the badan ext. with *p*-nitrosophenol under the same conditions have been unsuccessful. B. N.

Alizarin lakes. S. LIPATOV. *Melliand Textilber.* 9, 496–7(1928).—The combination of NO_2-Alizarin with Cu and Ba is a strictly chem. process following the laws of mass action. E. R. CLARK

Azoic colors on wool. S. C. TURNER. *J. Soc. Dyers Colourists* 44, 276–80(1928).—Expts. were made to det. the absorption of members of the Naphthol AS series by wool, and the naphtholated wool was examd. for damage by the caustic alkali used. The results are shown in 7 tables and 4 charts of graphs. Wool was not weakened by being naphtholated, nor did damage occur until the concn. of NaOH in the dye bath reached about 1.25 g. per l. Salt protected the fiber to some extent and increased the absorption of different naphthols in amts. varying from 0.8 to 82.7%. Salt slowly pptd. the naphthols from soln. at different rates for different naphthols. This action was stabilized by the addn. of Leonil S, which also acted as a protective colloid against damage by alkali, and, being a wetting-out agent, increased the penetration of the naphthol, thus promoting level dyeing. L. W. RIGGS

Indanthrene colors on rayon. GEORGE RUDOLPH. *Textile World* 74, 961–3 (1928).—See *C. A.* 22, 2276. RUBY K. WORNER

Testing the suitability of dyes for viscose rayon. A. J. HALL. *Am. Dyestuff Rept.* 17, 585–6(1928); cf. *C. A.* 21, 1357.—Sufficient uniform yarn from the same consignment of viscose should be reserved in storage for a large no. of tests. One-half of the test samples in skein form is uniformly immersed for 4 hrs. at room temp. in a 5% soln. of NaOH. The yarn is then well washed and is soured with HCl or AcOH, again is washed free of acid, hydroextd. and dried at 50°. In testing the suitability of a dye for viscose or other cellulose rayon, samples of yarn treated as above described and untreated samples are dyed together. If the dye used is an even one the 2 samples of dyed yarn will have nearly the same shade, but if the dye is an uneven one, the alkali-treated silk will be much deeper in shade than the untreated silk. L. W. R.

Selection of direct cotton dyes for viscose rayon. COURTAULDS, LTD. *Kunstseide* 10, 161–3(1928); cf. *C. A.* 22, 2060.—A new test, called the "temperature range test," is described, which involves testing the affinity of rayon for a given dye at different temps. (20–90°). Dyes showing max. affinity at 20° give the most even results on a large scale, while those dyes showing a max. affinity at 90° give the most uneven results.

Preference should be given therefore to those dyes showing max. affinity at 20°. These dyes, however, may be dyed at higher temps. A no. of direct cotton dyes are classified on the foregoing basis. FREDERICK C. HAHN

The development of dyeing and printing works in the last ten years. R. HALLER. *Z. angew. Chem.* **41,** 121–7(1928). E. H.

Physical chemistry of aniline black dyeing. ERNST KRAUS. *Melliand Textilber.* 9, 494–6(1928).—A consideration of ionic reactions involved. The max. fixation of $PhNH_2$ with min. loss by volatilization follows when the $PhNH_2$ salt is made with strong acids. The drying and oxidation should be carried out at the lowest possible temp. and the reaction mixt. should contain salts of strong bases with the acid used. E. R. CLARK

Studying Naphthol AS dyeing with cellophane. GUSTAV SCHWEN. *Melliand Textilber.* **9,** 674–5(1928).—By dyeing cellophane with Naphthol AS and coupling with the Fast Reds, etc., a material may be prepd. which facilitates study of changes in the dispersion of the color particles. Thus the effect of soaping is immediately seen in a change from transparency to cloudiness. With several combinations it was noted that hot pressing (230–250°) caused a reversal of this action, cloudy samples becoming clear. The temp. of this transition is related to the m. p. of the Naphthol AS-Fast red compd. E. R. CLARK

The physical condition of steam in continuous agers. P. AUG. DRIESSEN. *Melliand Textilber.* **9,** 670–1(1928).—While dyeing directions call for such conditions as moist steam free from air in the ager, it is rarely true that mill operatives have a proper conception of what is meant. It is suggested that "dry" steam be defined as steam so superheated that isothermal compression and considerable cooling do not induce mist formation. "Saturated" steam is invisible and mist-free, but very slight cooling or isothermal compression produces mist. "Damp" steam carries water as mist. In general the satd. condition is best for dye fixation. An atm. of satd. steam can only be attained by a very close check on temp. with due regard to barometric variations. E. R. CLARK

Colloresin D (dry) and its uses in textile printing. PFEFFER AND GMELIN. *Melliand Textilber.* **9,** 666(1928).—This substance is a cellulose ether produced by the I. G. It is sold as a dry, colorless wadding. In 8 times its wt. of warm water it swells slowly to yield a thick paste, the swelling being accelerated by the use of Nekal BX Heat induces coagulation while non-volatile alkalies and acids in general and water-sol. org. liquids such as glycerol decrease the viscosity. Tannins cause pptn. As compared with starch, gums, etc., for use in printing pastes, Colloresin offers the advantages of easier removal, freedom from mold growth, and better fastness of dyeings. In printing vat colors with its aid, the goods are printed with the Colloresin-thickened color mixt., and are then dried, treated with $Na_2S_2O_4$, steamed out of contact with air and soaped. Various other procedures are described. E. R. CLARK

The dyeing of Manila fiber. FRED GROVE-PALMER. *Textile World* **74,** 963–5, 1023(1928).—When cheapness is the main consideration, basic dyes may be used. In this process, the tannin which is a constituent of Manila hemp acts as a mordant. If fastness to light is important, substantive dyestuffs are preferable. Addn. of logwood-iron black will improve the dyeing of those fabrics which are to receive very strenuous treatment in wear. Luster is best obtained in a sep. bath after dyeing the fiber or fabric. RUBY K. WORNER

Bleaching and dyeing of muga silk. FRED GROVE-PALMER. *Am. Dyestuff Rept.* **17,** 579–90, 605–6(1928).—The crude methods of producing muga silk in India are described. In dyeing muga silk the gum is first removed and the fiber is put into a bleach bath made as follows: 1.25 gal. of tech. 85% HCO_2H and 0.25 lb. Na_3PO_4 are added to 120 gal. of soft water. To this soln. about 9 lb. of Na_2O_2 is added gradually with const. stirring and the reaction of the bath is adjusted by acid or alkali to a faint alky. when 2.5 pints of Turkey red oil is added to the bath and the goods are entered. The bath should be kept at 30° for 2 hrs., when it is raised slowly to 50° and is maintained at 50° for 2 hrs. The steam is then shut off and the bath, with the goods, is allowed to stand until the next day or longer. The bleached fiber is then rinsed in at least 3 waters. The dyeing of muga silk is about the same as for other silks, due allowance being made for the natural yellowness of the fiber, which is not entirely bleached out. L. W. RIGGS

Action of light on cotton dyed with vat dyestuffs. F. SCHOLEFIELD AND C. K. PATEL. *J. Soc. Dyers Colourists* **44,** 268–74(1928).—(1) Certain cases of tendering, which have occurred during the dyeing of viscose and cotton with vat dyestuffs, are to be attributed to the incidence of light on the dyed material during the dyeing process,

or before the first wash. (2) In other cases the effect of light at this stage is to produce a change in hue, and exceptionally, a partial or apparently complete destruction of the dyestuff. (3) The colors involved are mainly yellows and oranges, though Indanthrene Yellow G and Alizanthrene Yellow 6R are exceptions which produce neither change of shade nor tendering of cotton or viscose. (4) Similar effects were produced by impregnating the dyed material with weak alk. solns. of H_2O_2 and exposing to light. (5) The explanation of the chem. actions which occur is to be found in the production of H_2O_2 by exposure of the leuco-vat dye to air, and the activation of this H_2O_2 by light absorbed by the dyestuff. The alkali present in the dyebath accelerates this oxidation. (6) Should a second dyestuff be present this may be oxidized preferentially to the cellulose or to the original yellow or orange. Ciba Blue 2B was especially sensitive in this respect. (7) The foregoing results appear to support the theory that H_2O_2 is an immediate cause in the fading of dyed fabrics. L. W. RIGGS

Feltron C in the hat industry. RICHARD HAGEN. *Melliand Textilber.* **9,** 680–1 (1928).—This I. G. product restrains the browning of hat felts accompanying long contact with hot dyeing liquids. Consequently, its use facilitates the production of light clear shades. E. R. CLARK

The structure of individual fibers. CHARLES F. GOLDTHWAIT. Mellon Inst. *Proc. Am. Assoc. Textile Chem. Colorists* **1928,** 221–7; *Am. Dyestuff Rept.* **17,** 565–71.—The object of this paper is "to review briefly some of the more up-to-date ideas on the structure and behavior of textile fibers." The references are chiefly to work done in England during the past 2 or 3 years. L. W. RIGGS

Fiber cross-sections. A. HERZOG. *Kunstseide* **10,** 111–5(1928); cf. *C. A.* **22,** 2843.—Details are given for measuring the cross-sections of fibers, which consists in the following 3 stages: (1) direct measurement of sections under the microscope; (2) projection of microscopic image on a screen divided into squares of $^1/_4$ deniers; (3) measurement of the drawing of microscopic sections with the aid of drawing app. which operates without distorting the picture. FREDERICK C. HAHN

Delignification of jute fiber. JOGENDRA KUMAR CHOWDHURY AND RANENDRA KUMAR DAS. Dacca Univ. *J. Indian Chem. Soc.* **5,** 231–43(1928).—The study of delignifying jute is taken up. Beechwood creosote (I) is selected as the solvent for the lignone having the least effect on the cellulose. I hardens the jute fibers in the autoclave on account of its acidic nature converting the cellulose into hydrocellulose. Ten % C_5H_5N on the amt. of I used has the max. effect and is superior to NH_3 or $PhNH_2$, leaving the fibers with good tensile strength. Max. delignification was obtained without serious injury to the fiber by heating at 193–195° at 28–30 atm. pressure for 4 hrs. The addn. of HCl or I_2 as catalysts did not assist delignification. Analysis of the treated jute indicates a decrease in lignone from 19.7 to 4.4% and a furfural decrease from 11.0 to 8.7%. The β-cellulose content may be reduced in the jute by heating with 6% NaOH. It appears probable that in jute the incrusting matter is a lignone-cellulose complex and that the incrusting matter is very firmly fixed to the cellulose. The moisture in jute varied from 9 to 13%. D. H. POWERS

How warp-knit fabric can be approximately analyzed to aid duplication by trial and error. R. PRESGRAVE. *Textile World* **74,** 1451–3(1928).—The following factors are considered in regard to glove-silk fabric made on tricot and milanese machines type of cloth (tricot or milanese); nature and size of yarn used; distribution of yarn on the warps and in the needles; type of stitch (including ratio between warp lengths and the no. of bars used; gage of machine; length of rack ("quality"); ratio between finished width and knitted width; and weight of a unit area. RUBY K. WORNER

Testing knit-goods accessories. WM. DAVIS. *Textile World* **74,** 1453–5, 1163 (1928).—The ballistic testing machine, designed by the Cotton Research Assocn. of Great Britain for examg. ribbons, tapes and bands for breaking force, is described and illustrated. RUBY K. WORNER

Tensile testing of single wool fibers. P. KRAIS. *J. Text. Inst.* **19,** 32–6T(1928).—The "Deforden" app. for measuring the tensile strength, breaking extension, and torsional resistance of single fibers is described in detail, and examples of its application to tech. problems are given. There is no difference in strength between wool and "bristly" hairs of the same diam., but the latter have the higher percentage extension at the breaking point. B. C. A.

Plasticity of wool. J. B. SPEAKMAN. Univ. Leeds. *Proc. Roy. Soc.* (London), **B103,** 377–96(1928).—Wool contains elastic and plastic elements arranged in parallel. Wool fibers are imperfectly elastic in water as a result of the plasticity and rupture of fibrillae within the constituent cells. This fibrillar plasticity is due to hydrolytic changes assocd. with the peptide linkages; it may be reduced by reagents which react

or combine with the imido groups, thereby decreasing their affinity for water and inhibiting the hydrolysis of the peptide linkages. JOSEPH S. HEPBURN

Primary action of chromic acid on wool fiber. M. A. IL'INSKII AND D. I. KODNER. *Z. angew. Chem.* **41**, 283-5(1928); cf. *C. A.* **22**, 3329.—Wool fiber absorbs chromic acid from soln. even in presence of mineral acids, to form a complex in which the wool substance acts as a base, combining with about 10% of chromic acid. This is about the equiv. quantity on the assumption that the mol. contains 2 basic (NH_2) groups. The complex is stable towards water. B. C. A.

Phenomenon of wetting in the wool textile trade. J. B. SPEAKMAN. *J. Textile Sci.* **2**, 114-8(1928).—The development and tests of wetting agents are described. Under the use of wetting agents as assistants in the various processes in woolen textile manuf., several com. emulsifiers are considered. L. W. RIGGS

Yorkshire rivers purification—wool manufacturer's problem. ALFRED F. BARKER. *J. Textile Sci.* **2**, 97-9(1928).—The wool-scouring industry in Yorkshire has a by-product of approx. 34,000 tons of fats, 33,000 tons of soils and 11,000 tons of K salts. These by-products are among the chief sources of river contamination. This contamination may be avoided by having the wool cleaned before shipping or at the port of entry. L. W. RIGGS

Reducing the solubility of sericin. FRED GROVE-PALMER. *Am. Dyestuff Reptr.* **17**, 555-7(1928).—A "hard" silk contg. 17.8% of sericin and a "soft" Kashmir silk with 28 to 29% of sericin are compared. In the boil-off Kashmir silk loses its sericin more readily than hard silk. If the soft silk is treated from 15 to 30 min. with 4% HCHO at ordinary temp. the sericin became less sol. in boiling water, or in the soupling bath of 1% Marseilles soap at 70°. The loss of sericin was least when the silk was treated with 3% HCHO for 15 min. at temps. ranging from 72° to 85°. Above 85° the loss of sericin increased rapidly with the rise in temp. L. W. RIGGS

Shortcomings of rayon. CAMILLA. *Kunstseide* **10**, 120-1(1928).—The worst shortcoming of rayon is the brittleness of threads. Two factors to which the brittleness is attributed are the effects of iron and acid. A number of data are given which show the influence of acid on the Cu no. HCl and H_2SO_4 were used in concns. up to 1%. The influence of acid increases the Cu no. as high as 7 times that of the undamaged rayon With regard to the effect of Fe, it is stated that the brittle spots had a content of Fe exceeding that of normal rayon by 20%. FREDERICK C. HAHN

Uniform testing methods for rayon. H. STADLINGER. *Kunstseide* **10**, 245-8 (1928). The importance of standard testing methods for rayon is emphasized. Examples are given of inconsistent results obtained in different testing labs. A comm. consisting of both practical and academic men, formed in Germany to study this question, has adopted regulations concerning uniform methods for the following points: definition and discrimination of rayon and silk; tests for discriminating rayon and silk; kinds of rayon; detn. of titer, stretching, tensile strength, breaking tension. Detailed conditions are given for the tests. FREDERICK C. HAHN

Effect of moisture on the strength and elongation of rayon. Y. KAMI. *Kunstseide* **10**, 207(1928); cf. *C. A.* **22**, 1047.—Rayon shows increased elongation by wetting with water and at the same time loses its strength. The magnitude of the increased elongation and decreased strength is independent of the duration of moistening. FREDERICK C. HAHN

Cellulose acetate rayon-cotton mixed fabrics. K. WOLFGANG. *Kunsteide* **10**, 117-8(1928).—General rules are given for dyeing fabrics of this type. F. C. HAHN

Attack of cotton by mineral oils at higher temperatures. H. STÄGER. *Helv. Chim Acta* **11**, 377-86(1928).—A comparison is made of the attack of cotton wool by turpentine and transformer oil mixed with various org. acids. The results indicate that the disintegration of the insulation of transformers is not due to acids formed by oxidation of transformer oil, and support the view that interfacial forces are the important factor. B. C. A.

Effect of processing on affinity of cotton for metallic salts and Naphthol AS. KARL HENKEL. *Melliand Textilber.* **9**, 149-50, 501-2(1928).—The impurities in cotton have a bearing on the absorption of mordants and Naphthol AS. *E. g.*, in standard dyeing tests, Egyptian cotton absorbed 0.232 mol. Naphthol AS when dyed without boiling out. Boiled out cotton of similar type combined with 0.198 mol., bleached with 0.218 mol., and mercerized with 0.335 mol. Consequently where cotton cannot be dyed in the imperfectly purified state a certain extra consumption of dyes must be accepted, unless the material is mercerized. Of various metallic salts, cotton shows the greatest affinity for those of Al when the absorption is expressed in mols. E. R. CLARK

Estimation of china clay in sized cotton goods. GEORGE SMITH. *J. Textile Inst.* **19,** T323-8(1928).—The previously published methods for the estn. of China clay in sized cotton goods are criticised and the following method is recommended: From 1 to 2 g. of cloth is weighed accurately and is treated with 20 cc. of HCl (sp. gr. 1.1) in the boiling water bath until well disintegrated, when it is filtered through a Gooch or ashless filter and the residue is washed free of HCl. After drying at 100° to const. wt. the residue is ignited at a bright red heat in a Pt or SiO_2 crucible and weighed as "ignited clay." This wt. divided by the factor 0.87 gives the wt. of dry clay. If a sample of the original clay is at hand the correction factor may be detd. by expt. L. W. R.

The uses of esterified cotton. G. E. L. HIND. *J. Soc. Dyers Colourists* **44,** 280-1 (1928).—"The main purpose of esterifying cotton is to enable the production of numerous effects by piece dyeing instead of yarn dyeing, and apart from any saving in costs, its use should lessen the risks of stock-keeping and thus enable manufacturers to have at their disposal a more extended range of colors and also give quicker delivery. Patents covering the process are pending." L. W. RIGGS

Comparative p_H values of starches used by some North Carolina cotton mills. A. H. GRIMSHAW. *Textile World* **74,** 1327-31(1928); cf. *C. A.* **22,** 3798.—A detailed description of the procedure used for testing the p_H value of starches with the La Motte Roulette Comparator is included. RUBY K. WORNER

Soft water in the kier boil. S. F. ALLING. *Am. Dyestuff Rept.* **17,** 558(1928).—If not practicable to use soft water in all processes in the cotton mill, it should always be used in the kier boil for the removal of fats and waxes. L. W. RIGGS

Hypochlorite bleaching. M. MUNSCH. *Melliand Textilber.* **9,** 487-92(1928).—The current tendency to reduce the severity of purifying treatments preceding the chemicking of vegetable fibers has revived interest in the effect of HOCl on the non-cellulose compds. present in the raw material. The fate of N compds. is of special interest. The data given indicate that primary amino compds. yield NH_3 when treated with HOCl. This itself reacts immediately to form NH_2Cl whose presence may be detected by its characteristic odor, especially noticeable in linen bleaching; although sol., NH_2Cl has a mordanting action fixing colors from the chemic bath on the fiber being bleached. Cotton treated with an old linen bleaching chemic becomes stained. If the original N compds. yield secondary or tertiary N compds. on the fibers following alk. digestion, the chloroamines formed are insol. and yield active Cl and HCl on storage with resultant tendering. To remove them an addnl. alk. treatment rather than antichloring is required. E. R. CLARK

Chlorine as a bleaching agent for cotton. YNGVE DALSTRÖM. *Svensk Kem. Tids.* **40,** 106-18(1928).—A critical review of current methods in laundry investigations in which many tests are tabulated. Activated Cl is discredited as harmful to cellulose textiles. Cl forms oxycellulose much more readily than does O_2 and decreases more than tensile strength of cotton ribbons. This is explained by the formation of nascent HCl. Small quantities of sol. SiO_2 [60 mg. per l.] protect cellulose from injury by Cl. Perborates are favored as less injurious to fabrics and more efficient in oxidizing pigments. A. R. ROSE

Efficiency of the bleach or dye impaired by condition of wool. GEORGE RICE. *Dyer Calico Printer* **60,** 28(1928).—A general article, including a description of the steeping process for treating very dirty wools. RUBY K. WORNER

Zinc soap (damage to textiles). KEHREN. *Melliand Textilber.* **9,** 687-92(1928).—By reason of the corrosive action of mild alkalies including soap solns., Zn stains are fairly common on bleached and dyed fabrics. The diphenylamine acetate-$K_4Fe(CN)_6$ test for Zn brings out this type of damage clearly. E. R. CLARK

Colors for paint, lacquer and graphic industries (HEYL) **26.** Analysis of sulfonated oils (THOMAS) **27.** Dispersoidological investigations. XVIII. The structure of fibers (VEIMARN, *et al.*) **2.** Cleaning furs (Brit. 283,709) **29.** Dye soap (Can. pat. 281,874) **27.** Derivative from ligninsulfonic acid (Can. pat. 282,677) **23.**

Research and the Cotton Industry. Edited by R. H. Pickard. Manchester: The British Cotton Industry Research Assoc. 80 pp. Price to non-members, 5s. Reviewed in *J. Soc. Dyers Colourists* **44,** 23(1928).

Shirley Institute Memoirs, Vol. VI, 1927. Published by the British Cotton Industry Research Assoc., Didsbury. 132 pp. Reviewed in *J. Textile Inst.* **19,** 190(1928).

Dyes. DURAND & HUGUENIN A.-G. Brit. 283,482, Jan. 10, 1927. Brown mordant dyes are made by diazotizing an aminoazo compd. of the type R^1-N:N-R^2NH_2

(in which R^1 is an aromatic residue contg. an OH group in *o*-position to a COOH group and R^2 is an aromatic residue contg. a sulfonic or COOH group) and treating the resulting diazo compd. in an alk. or acid medium, at ordinary or higher temp., until its coupling powder has disappeared. Several examples are given.

Dyes. I. G. Farbenind. A.-G. Brit. 283,777, May 24, 1927. Black copying colors are obtained by coupling a diazotized dialkylated phenosafranine with a cresol, *e. g.*, from diethylphenosafranine and *p*-cresol.

Dyes. I. G. Farbenind. A.-G. Brit. 283,897, Jan. 19, 1927. Sol. dyes are obtained either by sulfonation of the monoazo dyes produced by coupling a diazotized *o*-nitroarylamine with an acetoacetic arylide or by coupling a diazotized *o*-nitroarylamine with a sulfonic acid of an acetoacetic arylide, of which examples are given. The products yield full yellow shades fast to light and to water when used as size colors, and dye wool evenly in clear yellow shades fast to light and fulling.

Dyes. I. G. Farbenind. A.-G. Brit. 283,979, July 17, 1926. The dyes obtainable by coupling *o*-hydroxy-diazo compds. with a naphthol or an arylaminonaphtholsulfonic acid are converted into Cr compds. by treating them with Cr formate or other suitable chroming compds. under the action of heat and pressure. Examples are given of dyes producing blue and brown fast shades on wool.

Dyes. Karl Thiess, Bernhard Deicke and Robert Schmidlin (to Grasselli Dyestuff Corp.). U. S. 1,684,331, Sept. 11. Dyes "more or less easily sol. in water," which dye animal fibers greenish yellow to brown-red tints of good fastness to light and to fulling, are obtained by condensing 1,3-dihalo-2,6-dinitrobenzene (or substitution products) with 2 mol. proportions of a 4-aminodiphenylaminosulfonic acid (or a substitution product). The condensation is preferably effected at boiling temp. A catalyst such as a Cu compd. or alc. may also be present. Several examples are given.

Dyes and intermediates. R. Vidal. Brit. 283,467, Jan. 8, 1927. Sepn. of amino compds. such as those produced by the reduction of nitroso compds. of α- and β-naphthol, phenol, *o*- and *m*-cresol and dimethylaniline by aq. Na_2S is effected by the use of NH_4 salts such as NH_4Cl or $(NH_4)_2SO_4$ as pptg. agents. A similar sepn. may be effected with products obtained by condensation, by means of Na_2S, of nitrosophenols, nitrosonaphthols and nitrosodimethylaniline with phenols or aromatic amines. When aniline, dimethylaniline or nitrosodimethylaniline is employed, alc. is added. Sulfuretted dyes are made by fusion with S of both the amino compds. and the condensation products sepd. as described.

Sulfur black dyes. R. Vidal. Brit. 283,468, Jan. 8, 1927. Di- or tri-nitrophenol or their mixts. are introduced into an aq. soln. formed from cryst. Na_2S, and after heating to complete the reaction the mass is cooled and nitrosophenol or nitroso-*o*- or *m*-cresol is added. The dye may be isolated by diln. with water and aeration to effect oxidation and pptn. with an NH_4 salt. Cf. *C. A.* **22,** 3536.

Anthraquinone derivatives. I. G. Farbenind. A.-G. Fr. 635,040, May 25, 1927. 1-Anthraquinonyl ketones are prepd. by the action of an oxidizing acid, preferably chromic acid, on a benzanthrone, in which at least 1 H atom in the Bz-1 or Bz-2 position is substituted by an alkyl, aryl, acyl, aroyl, nitro or carboxylic group. Thus 1-benzoylanthraquinone is prepd. from Bz-1-phenylbenzanthrone, and 1-acetylanthraquinone from Bz-1-methylbenzanthrone. Several examples are given. The compds. are *intermediate products for dyes.*

Azo dyes. Erwin Hoffa and Erich Fischer (to Grasselli Dyestuff Corp.). U. S. 1,684,275, Sept. 11. A 4-nitro-2-diazobenzene-1-carboxylic acid ester, *e. g.*, the diazo compd. from 4-nitro-2-amino-1-benzoic acid methyl ester, is caused to react with 2-hydroxynaphthalene-3-carboxylic acid anilide or similar compd. to obtain products which are suitable for use as pigment dyes. The components mentioned, coupled in the presence of a substratum, give a pigment of bluish red color of good fastness to light and suitable for use on *wall-paper.* Cf. *C. A.* **22,** 3995.

Azo dyes from pyridine. Iwan Ostromislensky (to The Pyridium Corp.). Can. 283,436, Sept. 18, 1928. Diazotized aniline and α,α-diaminopyridine are directly coupled in the proportions of more than 46.5 and less than 186 g. of the first and 109 g. of the second. The product is purified by recrystn. from boiling water.

Azo dyes and their chromium compounds. Société anon. pour l'industrie chimique à Bâle. Ger. 452,014, Nov. 4, 1927. 3-Aminonaphthalene-1,8-dicarboxylic acid is diazotized with any suitable diazo compd. and developed with any suitable developing compd. The azo dye resulting is then treated with a chromium-yielding reagent. *E. g.*, 10.7 parts of the above-named acid is dissolved in 150 parts H_2O with the aid of 10 parts of 30% NaOH, treated with 10 parts of soda, cooled and treated

with the diazo compd. produced from 8.5 parts of p-$H_2NC_6H_4SO_3H$. The dye is salted red and dried. Other amino sulfonic acids can be substituted. The above acid . is treated with 11.7 parts of 2,4,5-$O_2N(HO)(H_2N)C_6H_3SO_3H$ diazotized or various other chloronitromethylaminophenolsulfonic acids. 3-Aminonaphthalene-1,8-dicarboxylic anhydride (10.6 parts) is dissolved in 150 parts of H_2O with the aid of 10 parts of 30% NaOH, cooled to 20° with 30 parts of ice and treated with 25 parts of 30% HCl. Nitrite soln. (3.5 parts) is added and the diazo compd. is pptd. The resulting suspension is run into an alk. soln. of 6.9 parts of salicylic acid. After the developing is ended the excess alkali is neutralized with acid and the dye salted out, filtered and dried. 1, 8-Aminonaphthol-4,6-disulfonic acid (16 parts) is substituted for the salicylic acid. The dye produced from 3-aminonaphthalene-1,8-dicarboxylic acid and diazotized 3,4,5-$H_2N(HO)(O_2N)C_6H_2SO_3H$ is boiled in 950 parts of water with Cr formate soln. corresponding to 22.6 parts of Cr_2O_3. The Cr compd. is obtained by salting out 47.6 parts of dye resulting from the acid and diazotized 2,3,5-$HO(H_2N)$-$(O_2N)C_6H_2SO_3H$ in 950 parts of H_2O boiled with a CrF_3 soln. corresponding to 22.6 parts of Cr_2O_3. The product is washed with water, dissolved with warm, weak NaOH soln., neutralized with AcOH and sepd. 52.6 parts of the dye resulting from the acid and diazotized 1,2,3,5-$HO(H_2N)(HO_3S)C_6H_2CO_2H$ in 1000 parts H_2O are treated as in the preceding example. 53.3 parts of dye resulting from 4,8,2-$HO(H_2N)$-$C_{10}H_5SO_3H$ and diazotized 3,1,8-$H_2NC_{10}H_5(CO_2H)_2$ in 150 parts of H_2O is boiled with $Cr(OAc)_3$ soln. corresponding to 22.8 parts of Cr_2O_3. 58.7 parts of dye resulting from 2,6-$HOC_{10}H_6SO_3H$ in 1500 parts of boiling H_2O is boiled with $Cr(OAc)_3$ soln. corresponding to 22.8 parts of Cr_2O_3. 58.8 parts of dye resulting from 1,4-$HOC_{10}H_6SO_3H$ and diazotized 3,1,8-$H_2NC_{10}H_5(CO_2H)_2$ in 1800 parts of boiling H_2O is boiled with $Cr(OAc)_3$ soln. corresponding to 15.2 parts of Cr_2O_3. Cf. *C. A.* **21**, 3468.

Vat dyes. Walter Mieg and Albert Job (to Grasselli Dyestuff Corp.). U. S. 1,684,327, Sept. 11. Dianthraquinonylaminophenanthrenequinonylenes are obtained from α- or β-aminoanthraquinones, or, preferably, from α-aminoanthraquinones and 2,7-dihalophenanthrenequinones. A product may be thus obtained which dyes cotton from a vat copper-red shades. Various details and examples are given.

Water-soluble dyes. Otto Siebert, Karl Thiess, Bernard Schöner, Robert Schmidlin, Walther Benade and Bernhard Deicke (to Grasselli Dyestuff Corp.). U. S. 1,684,330, Sept. 11. Dyes of good fastness to light and suitable for use on *leather* or other materials are obtained by causing 4-nitro-4′-aminodiphenylamine-2-sulfonic acid or other suitable 4-aminodiphenylamine compd. to react upon 2-nitro-1-chlorobenzene or other suitable similar halogenated benzene deriv. (which may also contain a sulfonic group). Several examples are given.

Dispersing agents for dyes. Soc. anon. pour l'ind. chim. à Bâle. Fr. 634,864, May 23, 1927. The residues from the distn. of BzH, turpentine and colophony are treated with sulfonating agents such as H_2SO_4, oleum or chlorosulfonic acid and are used as addns. to dye baths particularly for dyeing artificial silk with insol. or slightly sol. dyes.

Dyeing. Courtaulds, Ltd., H. J. Hegan and J. H. Taylor. Brit. 283,672, Nov. 1, 1926. Tendering of cotton, artificial silk and similar materials by the immunizing treatment with tannic acid and $SnCl_2$ is avoided by a final treatment with a weakly alk. agent such as a soap soln. or a dil. Na_2CO_3 soln. The material to be immunized may be undyed or dyed with dyes of the indanthrene series or other dyes and the treated material is unchanged when treated with a direct dye.

Dyeing. J. W. Leitch & Co., Ltd., A. E. Everest and J. A. Wallwork. Brit. 283,838, July 8, 1926. Wool either alone or in the presence of other fibers (excepting silk) such as cotton or "viscose silk" is dyed by impregnating with a dil. neutral or slightly alk. soln. of an arylide of 2,3-hydroxynaphthoic acid in the presence of soap or other suitable org. solvent or dispersing agent and developing in a bath contg. a diazo compd. Numerous examples and details are given. Brit. 283,839 specifies dyeing silk, either alone or in the presence of other fibers, by impregnating it with an arylide of 2,3-hydroxynaphthoic acid in a soap soln. in the absence of added alkali, and developing in a bath contg. a diazo compd. Printed effects may be obtained, in either of these processes, by printing the impregnated material with a paste contg. a diazo compd. Cf. *C. A.* **22**, 2279.

Dyeing textile materials. Pieter Mijer (to The Two-Tone Corp.). U. S. 1,683,687, Sept. 11. Atomized liquid coloring material is allowed to settle from a homogeneous cloud-like mass on the material to be dyed so as to produce a regular effect without spotting. An app. is described. Cf. *C. A.* **21**, 330.

Removable partition, etc., for dyeing apparatus. W. GERBER. Brit. 284,126, May 24, 1927. Structural features.

Impregnating textiles and other materials. RANGAR S. SKANCKE. Norw. 44,698, Jan. 2, 1928. The materials are treated alternately with aq. solns. of alkali soaps and $Al(OAc)_3$. To the last-named soln. is added some AcOH and water-sol. acetates in order to establish and maintain a p_H in the soln. which favors the impregnating process.

Washable fabrics. ALBERT H. VANDAM (to Turner and Vandam, Inc.). Can. 283,611, Sept. 25, 1928. A washable woven fabric including a glossy white background a shadow design thereon printed with zinc oxide, slightly tinted with a fast dye, and a colored design printed over the shadow design is specified.

Waterproof composition. CARL G. A. LUNDBERG. Can. 282,994, Sept. 4, 1928. Waste material from wool or cotton manuf. or roved wool and cotton is treated with H_2SO_4 for 12 hrs. and the mixt. centrifuged to remove acid. The material is then washed with H_2O for 6 hrs. and again centrifuged, and material then dried. The purified material is treated for 30 min. with a warm (80°) soln. of 78 parts $ZnCl_2$, 14 parts $ZnSO_4$, 8 parts HNO_3 (by wt.) which has been allowed to boil 2 hrs beforehand. The material is liberated from any excess soln. and dried. The material is then impregnated with a rubber soln., cast into molds and subjected to pressure.

Impregnating fabrics. HARRY M. SPECHT. U. S. 1,683,849, Sept. 11. A pile fabric or the like is coated on the back with a compn. of fragrant gums such as benzoin, labdanum, tolu, balsam of Peru or styrax in soln., the soln. is dried and the face of the fabric is treated with a soln. which may also contain suitable fragrant material, the odor of which is suitable for blending with that of the material applied to the back of the fabric. Fabric thus treated is adapted for making powder puffs.

Improving cloth through a galvanic metallic precipitate. WERNER ENZ. Ger. 451,963, Oct. 29, 1927. CuS is pptd. from $CuSO_4$ by H_2S, filtered and drained. Sixty g. CuS is mixed with 60 drops of oleic acid and the mass is applied in a smooth layer to a copper plate. The fabric to be treated is placed on top of this and pressed out. This plate containing the fabric is inserted into a bath of $CuSO_4$ as the negative electrode. A copper plate acts as the positive electrode. A c. d. of 1–1$^1/_2$ amps./30 sq. cm. is used. The fabric after the electrolysis is washed in water, dil. KCN and again in water, then dried. Other materials than Cu and CuS can be used.

Painting silk. ADOLPH A. WETTSTEM. CAN. 283,227, Sept. 11, 1928. Lithopone 45%, yellow chrome 25%, gear varnish 22%, linseed oil 6% and turpentine dryer 2% are mixed together and allowed to age for 72 hrs. The mixt. is then applied to silk, artificial silk and rayons and gold dust or bronze dust is applied to said compd. on either or both sides of the fabric. Any surplus dust is removed by vacuum means from the fabric after the compd. has dried.

Weighting silk. ROBERT J. O'BRIEN, JR. (to Collway Labs.). U. S. 1,684,286, Sept. 11. Rubber in colloidal state in soln. is applied to silk threads.

Apparatus for washing artificial silk or other threads wound on bobbins. SPINNSTOFFWERK GLAUCHAU A.-G. Brit. 283,950, Jan. 21, 1927.

26—PAINTS, VARNISHES AND RESINS

A. H. SABIN

Microscopy of body colors. H. WAGNER AND J. KESSELRING. *Z. angew. Chem.* 41, 833–7(1928).—The use of the microscope in detg. the nature of the constituents of natural and artificial pigments is illustrated by several examples. Various colloidal constituents may be identified by their adsorptive power for certain dyes; *e. g.*, kaolin is colored by basic dyes, colloidal silica by both acid and basic dyes, kieselguhr by basic dyes, and hydrated alumina by acid dyes. Suitable dye solns. contain 1% of Brilliant Green, Acid Violet, or Orange II. Cryst. substances, such as fluorspar, calcite, or dolomite, are detected by the polariscope. B. C. A.

Colors for paint, lacquer and graphic industries. A general survey. GEORGE V. HEYL. *Paint, Oil & Chem. Rev.* 86, No. 1, 10–13, 20–1(1928).—The colors reviewed are classified as follows: (1) inorg., (*a*) natural minerals, (*b*) synthetically processed mineral colors; (2) org., (*a*) natural dyestuffs of animal or vegetable origin, (*b*) synthetically processed of coal-tar origin. Tables are given for classes 1-b, 2-a and 2-b, listing the com. name, chem. company, uses and remarks. Class 2-b is subdivided into color groups and covers also the relative fastness to oil at 30°, to H_2O at 50° and to sunlight. R. J. MOORE

The manufacture of submarine paints. JUAN GARCIA. *Quim. Ind.* **5**, 164–7 (1928).—A discussion of protective paints used for ship hulls and submarine structures. The best and most frequently used paints are: Hg oleate, linoleate, tungstate and resinate, or, better still a combination of Hg-Cu-As salts. Holzapfel's Cu-Hg paint developed in 1885 is one of the best. MARY JACOBSEN

The red-lead question. Action of red lead in rust-protecting paints. H. WOLFF AND R. SINGER. *Farben-Ztg.* 33, 1909–13(1928).—Rahder's statement (*Farben-Ztg.* **33**, 741–3(1927)) that red lead accelerates the corrosion of Fe is true only for the system: red lead–Fe–water, and does not hold for paints in which red lead forms the pigment. The oil adsorbed by highly dispersed red lead may vary very considerably, and is of more importance in detg. the rust-protecting capacity of a paint than is the total oil content. The oil content, degree of dispersion of the pigment, and the swelling capacity of a paint are not interdependent functions. The last-named depends on the free oil content, *i. e.*, on the oil which is not adsorbed on the surfaces of the particles of pigment. The protective action of the paint is due to a thin, almost mol. film in which the oil is present as an extraordinarily strong adsorption complex with the pigment and the base. The swelling capacity of the upper layers cannot therefore be a measure of the protective action of the paint, which is much more likely to be due to the formation of a protective film on the surface of the Fe. B. C. A.

Mechanism of the drying of red lead and white lead pigments. W. VAUBEL. *Z. angew. Chem.* **41**, 181–3(1928).—In the drying of pigments prepd. from red lead and white lead and linseed oil, although the oxidation of the linseed oil to linoxyn is the main process, subsidiary reactions occur as follows: (1) neutralization of the free acids present in the oil by the lead pigment, (2) hydrolysis of the linseed oil by the Pb compd. affording glycerol and lead linoleate, (3) reaction between the Pb compd. and glycerol, (4) neutralization by the Pb compd. of the mono- and di-glycerides present or formed in the drying process, (5) neutralization of the acetic acid or formic acid formed by oxidation in the drying process. Such hydrolysis of the linseed oil may be a source of streakiness in the pigment, owing to the hygroscopic character of the glycerol liberated, and the presence of glycerol so formed constitutes a danger to the effectiveness of the "anti-rust" pigments contg. lead, white lead and red lead reacting only very slowly with glycerol. Litharge reacts rapidly with glycerol, affording a solid compd., $C_3H_5(O\cdot PbOH)_3$, which on heating at 120–130° to const. weight is converted into $Pb[O\cdot C_3H_5(OPb)_2O]_2$, which can be used in the detn. of glycerol. $Pb(OH)_2$ reacts very slowly, the reaction being accelerated by heat. PbO_2 does not react cold, but reacts rapidly when heated; $PbSO_4$, $BaSO_4$, and lithopone are without action on glycerol. ZnO reacts more slowly than red lead, but faster than white lead. In addn. to their advantages in covering power, lead pigments thus possess advantages in their reactivity towards decomposition products formed in the drying process. B. C. A.

Sublimed blue lead. D. S. MOSBY. *Paint, Oil, Chem. Rev.* **86**, No. 1, 18–9 (1928).—The chem. compn., phys properties, manuf. and paint characteristics of sublimed blue lead are reviewed. Photomicrographs show the comparison of this pigment with red lead with regard to uniformity of size and shape of the particles. R. J. M.

Constitution of ultramarine. E. GRUNER. *Z. angew. Chem.* **41**, 446–50(1928).—A review of the various theories of the constitution and of the cause of the color of ultramarine. B. C. A.

Mineral black. H. M. LANGTON. *Ind. Chemist* **4**, 311–4(1928).—Mineral black is one of the very few naturally occurring black pigments. In Bavaria, the Tyrol, Spain, Italy, Switzerland and U. S. A. (Penn.) it is made by grinding and levigation or wet-grinding of a highly carbonaceous shale or slate. The pigment is usually blue-black or brownish black. Around Bideford in Devonshire the mineral occurs in a pasty form. An account of the geology and the history of these deposits is given, also an account of the method of mining. Analyses of the product obtained by different methods, its phys. properties, and its appearance under the microscope are set forth. A discussion of its behavior as a paint pigment, as a cement pigment, as a rubber reinforcing pigment, in tile manuf., and as a pigment in the manuf. of tarpaulins, linoleum, paper and vulcanite concludes the article. A bibliography of literature on mineral black and related black pigments is included. E. G. R. ARDAGH

Recent improvements in the quality of American lithopone. JAMES E. BOOGE. *Paint, Oil, Chem. Rev.* **86**, No. 1, 18b-c(1928).—Lithopone production is now over 175,000 tons a year and has passed both white lead and ZnO. Recent improvements in texture and ease of mixing are reviewed. *Texture* is defined as freedom from coarse material, grit, hard aggregates, etc. Three tests for hiding power in general use are outlined, *viz.*, indirect tinting strength, cryptometer and paint-out test. The latter is pre-

ferred and a method given. Relative hiding powers so detd., with lithopone as 100, are as follows: American process ZnO 85–90, titanox 120–135, 50% ZnS lithopone 135–140; ZnS and TiO_2 run between 200 and 300. Methods for testing texture and ease of mixing are given. R. J. Moore

Bleaching of linseed oil. K. Würth. *Farben-Ztg.* **33**, 1852–3(1928).—Linseed oil was treated with ozonized air, a large, moving surface of oil being exposed during the process. The oil was rapidly bleached and its consistency unchanged, but on gentle heating, the oil assumed a brownish color and a gas having a strong odor was evolved. Similar results were obtained by treating the oil with air while exposed to ultra-violet light from a Hg lamp. The presence of moisture in the air or in the oil may influence the processes involved. B. C. A.

Varnish resins in the Far East. A. F. Suter. *Oil Colour Trades J.* **74**, No. 1561, 777–8(1928).—These notes of an extended tour for the purpose of studying the origin of various varnish resins deal with the damars and copals of Ceylon, Federated Malay States, Dutch East Indies, Sumatra, Java, Celebes and Borneo. R. J. Moore

Lacquer and varnish films. P. S. Kennedy. *Wood Industries* **50**, 1–6(1928).—Varnish- and lacquer-film failures on wood are identical as to fracture. The same phys. causes produce both. Each type is definitely recognized. Varnish-film fractures may return to their original state; lacquer-film fractures never. Cracks can be detected under the microscope in $^3/_4$ of the time before becoming macroscopic. Varnish dries to a plastic film; lacquer dries to a tight film. Varnish is always increasing in vol., whereas a lacquer film is decreasing. Easy-rubbing nitrocellulose lacquer is unsuitable for durable service on wood. Humidity cracks are possible with nitrocellulose lacquers, and improvement in this respect is possible by use of elastic lacquer for undercoats with varnish for topcoats, use of a combination varnish-lacquer product, or the use of a lacquer with a suitable synthetic plastic base. The term lacquer should refer only to quick drying and hardness; not to the components. It is possible to produce a synthetic lacquer material resistant to ultra-violet rays and one which resists the workings of wood both in and out of doors. E. M. Symmes

Nitrocellulose lacquers. S. S. Smith. *Ind. Australian Mining Standard* **79**, 490(1928).—A review from the English viewpoint. E. M. Symmes

Duco—a product of management. W. A. McGarry *Management* **31**, 37–42 (1928). E. M. Symmes

Constitution of colors (Heyl) **25**. Formaldehyde (Coulouma) **10**. Esters of glycolic acid (Ger. pat. 463,139) **10**. Painting silk (Can. pat. 283,227) **25**. Repairing cracked patent leather (Brit. pat. 283,995) **29**.

Luttringer, A. D.: **La linoxyne et le linoléum.** Encyclopédie du Caoutchouc et des Matières Plastiques. Paris: A. D. Cillard. 169 pp. F. 36.

Smith, S.: **The Cellulose Lacquers.** London: Sir Isaac Pitman & Sons, Ltd. 145 pp. 7s. 6d.

Paint. Liebeskind Williams. Can. 282,463, Aug. 14, 1928. A white paint contains 92.3% Zn, 2.3% Na_2CO_3, 3.1% flowers of S, 1.5% NaCl and 0.8% ultramarine blue by wt., fused, finely ground and mixed with a vehicle. Cf. *C. A.* **22**, 1486.

Paint vehicles and fillers. W. T. Branscombe and R. C. L. Everleigh. Brit. 283,998, July 24, 1926. An oily vehicle such as linseed oil and turpentine carries in suspension a pore-filler made by treating blown linseed oil or other suitable fatty oil with a small proportion of S or S chloride.

White lead. Holzverkohlungs-Industrie A.-G. Ger. 463,938, July 19, 1928. A basic lead acetate soln. contg. less PbO than is required for the prepn. of $Pb(OH)_2$-$2PbCO_3$ is pptd. with carbonates and refluxed with stirring. The product corresponds to chamber white lead in all properties.

Primings, varnishes, paint vehicles. William T. Branscombe and Richard C. L. Everleigh (to Pinchin Johnson & Co., Ltd.). Can. 281,837, July 17, 1928. A priming material, varnish or paint vehicle consists of a fatty oil (linseed oil) treated with S or SCl_2. The reaction is controlled to prevent coagulation by diln. with turpentine, the mass before becoming too stiff having added thereto a thinning agent, and driers, varnish, resins or a mixt. thereof.

Solvents for use in nitrocellulose lacquers, etc. J. Schindelmeister. Brit. 283,619, Oct. 6, 1926. Esters of borneol, isoborneol or terpineol such as the formates, acetates, butyrates, oxalates, phthalates and salicylates are used as solvents or colloid-

ing agents, alone or with other substances such as EtOH, PrOH, BuOH or AmOH, cyclohexanol, C_6H_6 or toluene. Synthetic resins, natural resins, coloring substances, fillers, etc., may be added to the compns.

Nitrated carbohydrate solution. GARRETT H. PETERS (to Hercules Powder Co.). Can. 283,058, Sept. 4, 1928. In a non-blushing soln. contg. nitrated cellulose and volatile constituents including a solvent and diluent the volatile ingredients of the soln. are substantially immiscible with water. *E. g.*, a soln. for use as a *lacquer* contains 10.5 parts nitrocotton on the dry basis, 30 parts butyl acetate, 45.5 parts toluene, 7.5 parts ester gum and 5 parts tricresyl phosphate.

Waterproofing paste. GERALD B. DYDE. U. S. 1,684,086, Sept. 11. A waterproofing paste suitable for use on leather, canvas or imitation leather is formed of boiled linseed oil 1 gal., turpentine 1 pint, Burgundy pitch 1 lb. and yellow beeswax 1 lb.

Furnace (with an endless conveyor) for use in lacquer enameling, etc. ALLGEMEINE ELEKTRICITÄTS-GES. (to International General Electric Co.). Brit. 283,591, Jan. 15, 1927.

Linoleum. C. F. HUMPHREYS and J. C. MCCARTHY (to Armstrong Cork Co.). Brit. 283,947, Jan. 22, 1927. A sheet of linoleum which may comprise a backing and a layer formed of ground cork, wood flour and linseed oil is indented with a pattern by use of a ribbed embossing plate. Various mech. features are specified.

Synthetic resin. AUGUSTUS E. MAZE. U. S. 1,683,835, Sept. 11. Diacetone alc. 1 and CH_2O 3 mol. proportions are caused to react in the presence of an alkali such as NaOH to form a product which is sol. in esters and ketones.

Synthetic resins. M. T. HARVEY. Brit. 283,803, Oct. 11, 1926. Cashew nut shell oil is condensed with an aldehyde such as CH_2O, with or without the presence of HCl or a basic catalyst. An oily product may be first obtained by use of temps. of 100–200° and this product may be further heated under pressure to obtain a hard compact material. The products may be used for *lacquers, elec. insulating*, etc.

Artificial resin. FRITZ SEEBACH (to Bakelite G. m. b. H.). U. S. 1,683,701, Sept. 11. A condensation product formed from a phenol, CH_2O and aniline, toluidine, α- or β-naphthylamine or other suitable aromatic amine, is fusible and sol. in org. solvents, contains about 77–78% C, 5–6% H, 4% N and has a mol. wt. of 370–380. Cf. *C. A.* **22,** 3308.

Manufacture of products from artificial resins. "RESAN" KUNSTHARZFABRIC A.-G. Austrian 108,680, Sept. 15, 1927. A bakelite or other artificial resin in the liquid state is poured over a shaped impermeable base and is hardened thereon. The base may be made of porcelain, glass, or a readily fusible alloy, and in the last case the base may be removed, when the resin has hardened, and be replaced by wax or other suitable filling.

Ester resins. I. G. FARBENIND. A.-G. (Gerhard Balle, inventor). Ger. 463,842, July 19, 1928. Acetylene is passed into resin acids, *e. g.*, colophony or Manila copal, fused or in solvents, *e. g.*, Me_2CO with or without catalysts, *e. g.*, $Hg(OAc)_2$, at ordinary or high temp. The ester resins obtained are sol. in ordinary lacquer solvents and in fatty oils and have high drying power.

Purifying soluble phenol-aldehyde resins. FRITZ SEEBACH (to Bakelite G.m.b.H.). U. S. 1,683,702, Sept. 11. A colloidal soln. is formed of the resins with alkalies in a quantity insufficient for transforming the resins into their alkali metal salts but sufficient for neutralizing the free phenols and avoiding the hydrolysis of the phenol alkali salts formed; the resins are then pptd. by water. Cf. *C. A.* **22,** 3792.

Resin-like condensation products from amines of the aromatic series and formaldehyde. I. G. FARBENIND. A.-G. Ger. 452,009, Nov. 2, 1927. *o*-Toluidine (107 parts) dissolved in the same quantity of 90% alc. is mixed for several hrs. with 100–120 parts of 30% CH_2O. An oily reaction product seps., which is freed from alc., H_2O, *o*-toluidine and other by-products by gradually heating under vacuum up to 180°. The yield is 90% based on the toluidine. The resulting product is like colophony; it softens at 50°. Aniline (200 parts) is dissolved in 320 parts of 94% alc. and stirred below the boiling temp. for 1.5 hrs. with 225 parts of 30% CH_2O. The process is completed as above. Other examples are: 30 parts of a mixt. of chlorotoluidine isomers, 60 parts of 90% alc. and 30 parts of 30% CH_2O; 150 parts α-naphthylamine dissolved in 300 parts of 94% alc. and 120 parts of 30% CH_2O; 150 parts β-naphthylamine in 450 parts of 94% alc. and 160 parts of 30% CH_2O.

27—FATS, FATTY OILS, WAXES AND SOAPS

E. SCHERUBEL

The deterioration of fats and the development of rancidity. W. L. DAVIES. *Ind. Chemist* **4,** 269-72(1928); cf. *C. A.* **22,** 3308.—Rancid aromas and flavors are due to the products of autocatalytic oxidation. Measuring the O_2 absorbed gives a time-O curve usually showing a period of induction followed by logarithmic absorption. The keeping quality of a fat may be deduced from this period of induction. Values for comparing the keeping qualities can be obtained by working at 70-85° to shorten the time required to secure the information, though the fats themselves are stored at 0° to 15°. The first step in oxidation is the formation of a fat peroxide at the position of the double bond in the unsatd. acids. This will form H_2O_2, which in turn will oxidize traces of $C_3H_5(OH)_3$ to aldehydes and hydroxy aldehydes. At the same time unsatd. acids will break down to simpler acids and aldehydes, or simpler acids may be partly oxidized by β-oxidation to ketones. The oleic residue can take up O_2 again, so that the process is autocatalytic. An acid condition of the original fat favors development of rancidity. Moisture, high temp. and light all hasten rancidity. Air should be kept away as much as possible. Traces of metals (except Sn) present as soaps in the fat are catalysts to oxidation, even in absence of light. Containers for strong fats should, therefore, be tinned or lacquered. Cu is the most active of the metal catalysts of oxidation, and Sn and Al are the least active. The following tests for rancidity are given in detail: (1) the Kreis test; (2) oxidizability of water-sol. constituents and of steam-volatile constituents; (3) hydroxy acids of high mol. wt. Color tests are given for detecting min. traces of Cu and Fe. Cu is 12 times as active as an oxidation catalyst as Fe. The development of rancidity by microörganisms is discussed. The presence of nitrogenous compds. hastens the outset of biologically induced rancidity. The fishy odor and flavor of butter are due to the Fenton oxidation of the choline to trimethylamine and aminoethyl alcohol. The glyoxal, formed by the partial oxidation of glycerol, acts in a similar way to a peroxide. Thus this compd. helps in the splitting off of NH_3 and catalyzes the onset of rancidity. Formation of NH_3, together with fatty acids, tends to keep the aq. phase neutral, at the same time causing a higher concn. of oxidizable compds. in the aq. phase. Too alk. a medium will cause more sapon. than an acid medium, and hence will hasten rancidity. This is particularly the case when Na and K soaps are present, though Ca soaps have little effect. The use of refined oils free from nitrogenous impurities does away completely with rancidity in soaps. Traces of the heavy metals produce discoloration in soaps. Antioxidants will prolong the period of induction and retard the subsequent rate of oxidation. Especially effective antioxidants are basic unsatd. compds. such as amines, aromatic phenols and inorg. basic reducers (*e. g.*, $SnCl_2$ and $Na_2S_2O_3$). These inhibitors retard or prevent oxidation only for a time. Subsequently the speed of oxidation is the same as before. The oxidation of rubber during aging and curing is closely related to the oxidation of fats. The use of antioxidants finds more application in the rubber than in the oil industry. Bibliography. E. G. R. ARDAGH

A new characteristic of coconut fat (caprylic acid number). J. GROSSFELD. Govt. Food Research Inst., Berlin. *Z. Untersuch. Lebensm.* **55,** 354-75(1928).—The *caprylic acid number* is detd. on 500 mg. of fat and is the amt. of fatty acid expressed as cc. of 0.1 *N* soln. in 5 g. fat and sepd. by fixed diln. of the soap solns. by $CuSO_4$ to form Cu salt. By this procedure the caprylic acid no. of coconut fat ranged from 17.4 to 21.8; palm-kernel fat 7.9 to 11.6; butter fat, 4.1 to 5.9; lard 0 to 0.3; and cacao fat 0. The technic is fully described. The test should serve to identify coconut oil. C. R. FELLERS

German practice in recovery of wool grease. ERNEST WOLFF. *Chem. Met. Eng.* **35,** 473(1928).—The alk. soap liquors from the wool scouring are mixed with H_2SO_4 and run into successive pits through which they flow continuously and sep. a sludge contg. wool fat, fatty acids of the soap and dirt. The sludge gradually fills the pits, from which it is pumped into a brick-lined tank, where it is heated previous to filtering. The filtered mud is heated and run into extn. app., where it is treated with benzine. Five extns. are necessary and the last 3 are used for further extn. Neutral grease is produced from the evapn. of the benzine soln., the benzine being recovered. The grease is refined by NaOH and alc. and the fatty acids are recovered. Lanolin is made by evapg. the benzine soln. to 0.8 sp. gr. and bleaching with fuller's earth, after which the benzine is recovered. The lanolin is deodorized. E. SCHERUBEL

Behavior of fats and oils in ultra-violet light. M. HAITINGER, H. JÖRG AND V.

REICH. *Z. angew. Chem.* **41**, 815–9(1928).—The fluorescence colors under ultra-violet light of several oils and fats, pure and in soln., are recorded, with reference to the detection of adulterants in butter, lard, cacao butter, olive oil, etc. A characteristic zoned fluorescence is noted when filter paper partially immersed in oil or oil soln. is satd. by capillary rise of the liquid. B. C. A.

Determination of the iodine number by means of thiocyanogen. H. STADLINGER. *Pharm. Ztg.* **73**, 340–2(1928); cf. *C. A.* **22**, 1488.—The comparatively new application of $(CNS)_2$ in the evaluation of fats is described, and applications of the procedure are indicated and discussed. The method involves addn. of the reagent (made up of specified amts. of Br, CCl_4, AcOH and $Pb(CNS)_2$) in excess to a weighed amt. of the fat, keeping the resulting mixt. 24 hrs. in the dark, then detg. the excess of reagent by addn. of KI and titration of the liberated I. The results, being expressed in terms of I, are comparable with the ordinary I values. Since $(CNS)_2$ unites only with 1 double, not with a triple, linkage and then only when 2 or more double linkages are present in the mol., a comparison of this thiocyanate value with the ordinary I value readily affords a means for detg. the nature and amts. of the several unsatd. compds. present. W. O. E.

Determination of halogen number by the aid of aqueous solutions. ALBERT HANSON. *Dansk. Tids. Farm.* **2**, 89–112, 112–3(1928).—The meaning of the halogen no. and its use in the detn. of degree of unsatn. and positions of double bonds are briefly discussed. The different methods of detg. the halogen no., Hübl's, Hanus, Wijs' and Winkler's, are described and discussed in considerable detail; whence both the desirable and undesirable features are pointed out. Winkler's method possesses several advantages over the others, and is therefore investigated further. Some of the faults pointed out by several investigators are the sensitivity to light, loss of Br_2, and low results on oils with high halogen no. Mixt. I was the one suggested by Winkler, *e. g.*, 25 cc. 0.2 N $KBrO_3$ + 10 cc. CCl_4 + 1 g. KBr dissolved in 15 cc. H_2O + 10 cc. 10% HCl soln., and Mixt. V was the same as I, except 5 g. KBr instead of 1 g. Expts. were made on olive oil (halogen no. = 84.5), linseed oil (h. no. = 175), and cod-liver oil (h. no. = 157.6) as detd. by Hübl's method. The results were: (1) Intermittent shaking of the reaction bottle is not necessary. (2) Less Br_2 loss occurs with Mixt. V than with Mixt. I. (3) The reaction period, when Mixt. V is used, must be 2 hrs. for non-drying oils, and 20 hrs. for drying oils. Prolonging the periods gave no appreciable increase in Br_2 consumption. The above periods gave results that agree with Hübl's. (4) The halogen used should be 40–50% in excess of the amt. required and may be calcd. from $(B - A)/B \times 100$; B = original amt. of halogen and A the amt used, as expressed in cc. 0.1 N $Na_2S_2O_3$, also the weight in g. of oil taken should be 33 ÷ approx. halogen no. (5) The addn. processes and the substitution processes, the latter hastened by light, do not take place simultaneously. At first the greater part of the addn. process takes place and when this becomes slower, *e. g.*, when there is an excess Br_2 in the CCl_4 layer, substitution starts. With the wt. in g. of oil = 33 ÷ approx. halogen no., the soln. is not sensitive to light for 8–10 min. (6) A lightproof box in which the reaction bottle may be placed during the expt. is described. (7) Hanus' method is only very slightly sensitive to light. (8) It was found that adding I_2 to a soln. of Br_2 in CCl_4 produced an increased light absorption at 600–400$\mu\mu$. (9) Addn of KI to the reaction mixt. decreases the sensitivity to light somewhat, but certain disadvantages follow, making this method of improvement questionable. (10) A different solvent was tried, *e. g.*, 5 cc. ether, 5 cc. CCl_4, and as reagents 25 cc. 0.2 N $KBrO_3$ in which 0.30 g. KBr and 0.415 g. KI were dissolved. The halogens were liberated by addn. of 7 cc. 25% HCl. A drop of NaOH soln. makes this soln. very stable. With this method, the sensitivity to light is practically overcome; the time for drying the oil is reduced to 6 hrs. The results are very good if at least a 40% excess of halogen is used. However, the amt. of oil must be almost exactly 33 ÷ approx. halogen no or unreliable results are obtained. H. does not wish to substitute this method for Winkler's, because the excess of halogen, and the weight of oil sample must be within such narrow limits as to make it difficult of consistent results. O. A. NELSON

Hydrogenation of polymerized oils. I. LARYUKOV. *Oil and Fat Industry* (Russia) **1928**, No. 1, 27–8.—Consumption of H is considerably decreased when the hydrogenation of polymerized oils is carried out at a temp. of 300–315° for 40–50 min. The hydrogenated oil obtained is of the same quality as the low-temp. hydrogenated oil. A. A. BOEHTLINGK

Analysis of sulfonated oils. W. H. THOMAS. *Am. Dyestuff Rept.* **17**, 587–9 (1928).—Details for detg. the H_2O and ash are given and also for the titration methods ...m. Leather Chem. Assoc. L. W. RIGGS

A few notes on fish oil. JOSÉ SAMPAIO MOREIRA. *Chimica e industria* **2**, 413–6, 439–41(1927).—Review without references. MARY JACOBSEN

Color-glass standardization. D. B. JUDD AND G. K. WALKER. *Oil and Fat Ind.* **5**, 16–26(1928).—A large no. of red Lovibond glasses for grading vegetable oils were compared with a standard glass and graded by means of a Martens photometer. The engraved numerals were found to be only an approx. index of color, previous findings as to inaccuracies in the region 7.0–8.0 being confirmed (samples engraved 7.6 covering a range of 1.1 red units). Results indicated that the Priest and Gibson scale departed by about 0.1 from the av. Lovibond red glass of the order 7.0–8.0 used in the U. S. B. C. A.

Examination and evaluation of bees wax. E. ELSER. *Schweiz. Chem.-Ztg.* **1928**, 27–32, 40–5.—A precise method of detg. m. p. of waxes, using a 1.5-mm. capillary tube in a bath, the temp. of which is raised 4° per min. from an initial temp. not above 10–15°, is described. Tables are given showing the variation of m. p. of three fractions of beeswax when mixed with varying amts. of carnauba wax, ceresin, Japan wax, spermaceti, and paraffin waxes (m. 58° and 48°). Each wax is considered in some detail and its characteristic effect on the m. p. of beeswax demonstrated in a series of curves. The author concludes that modern chem. and physicochem. research has shown that the thermal method of analysis of beeswax is simple and exact, and permits the detection not only of the nature but the percentage of adulteration. B. C. A.

Standard analysis of soap. ANON. *Chem. Eng. Mining Rev.* **20**, 363–5(1928).—Directions are given for detg. moisture, insol. matter, total acids, resin acids, free alkali and matter insol. in alc., alkali carbonate and silicate. W. T. H.

Soap perfuming notes. ANON. *Perfumery and Essential Oil Record* **19** (Special No., Aug., 1928) 326–30.—The keeping quality of soaps and perfume material is reviewed. The following substances retard oxidation and should be used in soap perfumes: anisole, benzyl benzoate, borneol, carvacrol, citronellol, coumarin, cinnamon-bark oil, clove oil, cymene, eucalyptol, eugenol, guaiac wood oil, isoeugenol, isosafrole, phenylpropyl alc., patchouli and petitgrain oil, phellandrene, resins, safrole, sandalwood oil, thymene, thyme oil, thymol. The principles of incompatibility and stability of various substances are as follows: alcs. generally are stable as geraniol; the cinnamic and the aliphatic aldehydes are less stable and vary greatly; benzaldehyde is the most unstable; anisaldehyde is a little more lasting; vanillin is sensitive to light; heliotropin and the aliphatic kind are the most permanent. The ketones vary; the aromatic kind resist the action of light and alkali; artificial musks are stable but not to light; ionones easily polymerize. The aliphatic, as methyl nonyl ketone, are very lasting. Phenols form salts with alkali; some as eugenol are stable. The halogen compds., like bromostyrene, are fairly stable and reliable with alkali. The ethers, such as *e. g.*, Ph_2O and nerolin, are resistant to light and alkali. Esters are all saponifiable and only permanent in neutral soap. The lactones, such as coumarin, are reliable except against light. The acids, such as phenylacetic, benzoic and cinnamic, are stable. The terpenes are O carriers and form hydroxy fatty acids. The general principle followed for constructing perfume formulas is to rough out a formula of the stable primary materials; where they are not all stable a protective agent is added either by way of a fixative or a combined modifier and fixative of the same odor class. The modifiers are then added; but the fixative is the most essential factor and should always be on the generous side and preferably of the resinous kind. E. S.

Influence of area of active surface of a Ni catalyst on the velocity of hydrogenation of oils (JÓZSA) 2. Apparatus for treating oil (Can. pat. 283,501) 22.

Zeitschrift für physikalisch-chemische Seifenforschung. (New Journal.) Vol. I, No. 1. June, 1928. Edited by L. Zakarias, of Prague. Published monthly. Annual subscription 12 German Marks.

Extracting fat from bones of whale, seal and other large marine animals. AKTIESELSKAPET FORSÖKSDRIFT. Norw. 44,755, Jan. 16, 1928. Mech. features of process and app.

Sulfonated fats. HEINRICH BERTSCH (to H. Th. Bohme A.-G.). Can. 283,397,

Sept. 18, 1928. Sulfonation products are obtained by treating a polymerized fatty substance with H_2SO_4 in the presence of AcOH.

Extraction of oil from whale and seal speck. AKTIESELSKAPET FORSÖKSDRIFT. Norw. 44,463, Oct. 10, 1927. The speck is disintegrated by cutting or chopping in a suitable mech. app. and is heated to about 50° under reduced pressure until approx. half of its water content has been removed. By this treatment the physical condition of the cellular tissues is completely changed in such a way that the oil can easily be sepd. by pressing.

Extracting oil from fish liver and similar fatty materials. AAGE W. OWE. Norw. 43,956, April 25, 1927. The liver mass is frozen in order to burst the cellular tissues and is then thawed out again. The oil is sepd. by filtering, centrifugalizing or in other known ways. Before or after the freezing but before the thawing the liver is disintegrated in a mech. app. Cf. *C. A.* **21**, 2196.

Apparatus for the extraction of oil from fish liver ROLF RÖED. Norw. 44,190, July 4, 1927.

Boiler for the production of oil, etc., from whale flesh. THORALF SÖRLLE and KNUT T. FOSSHEIM. Norw. 44,158, June 27, 1927. Mech. features.

Recovering oil from tin plate, etc. AMERICAN SHEET & TIN PLATE CO. Brit. 283,614, Sept. 13, 1926. Palm oil or the like is removed from tinned plates suitably, by washing with an alk. soln. which forms an emulsion, the oil is sepd. from the bulk of the water, as by breaking the emulsion with acid or by the action of heat, and water is sepd. from the oil by vaporization before further use of the recovered oil. H_2SO_4, niter cake, waste pickle liquor, lime, $CaCl_2$, $FeSO_4$, Na_2SO_4 or alum may be used in breaking the emulsion, or the oil may be extd. with a solvent. An app. is described. Cf. *C. A.* **22**, 3389.

Separating oil from aqueous emulsions. AMERICAN SHEET & TIN PLATE CO. Brit. 283,830, Sept. 13, 1926. In sepg. oil such as palm oil from an emulsion with an alk. soln. (such as is obtained in recovery of the oil from tin plate as described in Brit. 283,614, preceding abstr.), enough alk. soln. is added to purify the oil partly, the emulsion is broken by addn. of an acid and the oil is sepd. from the broken down emulsion, *e. g.*, by gravity. An app. is described.

Soap. HANS HOFFMÜLLER VON KORNATZKI. U. S. 1,684,336, Sept. 11. A soap which is stated to be a "*remedy for rheumatism*" comprises 6 parts by wt. of a soap mixt. obtained from fatty oils such as palm, cotton and coconut oils and NaOH, together with 95% alc. 1, freshly prepd. rectified amber oil 1, and succinic acid 0.2 part. Cf. *C. A.* **21**, 3760.

Dye soap. WOLF KRITCHEVSKY and HAROLD C. PRUTSMAN (to William Citron, trustee). Can. 281,874, July 17, 1928. A dye is incorporated in the metallic salt of a sulfocarboxylic acid.

Detergents. I. G. FARBENIND. A.-G. Brit. 283,786, Oct. 13, 1926. Cleansing compns. and emulsifying agents forming clear aq. solns. suitable for use in the *textile* and *leather industries*, comprises the oily O-contg. org. substances insol. in water obtained by the hydrogenation of oxides of C or by the hydrolysis of the compds. formed by absorbing in H_2SO_4 the unsatd. hydrocarbons obtained by cracking, mixed with a soap or soap-forming materials or with substances such as turkey-red oil having "soap-like" properties. Solvents such as alcs. or hydrocarbons or paraffin or $C_{10}H_8$ may be added.

Detergent. ZIMMERER-WERK, CHEM. FABRIK. Ger. 451,986, Nov. 4, 1927. Two parts by wt. of pure extd. almond bran is mixed well with 2 parts of calcined kieselguhr and 1 part of pure soap powder. To this is added 1 part of a mixt. consisting of 3 parts of cyclohexyl acetate and 1 part of citronella oil. Cyclohexane may be used instead of cyclohexyl acetate.

28—SUGAR, STARCH AND GUMS

F. W. ZERBAN

Colloid chemical research work in the sugar industry during the past few years. P. HONIG. *Arch. Suikerind.* **36**, 591-612(1928).—A survey is presented of research work done by different chemists on colloid chemistry in sugar manuf. The expt. station in Java will study the different points in order to establish methods to be followed at the various stations in the factory. P. R. PEKELHARING

Rebuilding the sugar mill Redjoagoeng (Java). Q. A. D. EMMEN. *Arch. Suiker-*

ind. **36**, 520–9(1928).—Description of the elec. installation of the mills at Redjoagoeng.
P. R. PEKELHARING

Electrification of sugar mills. J. C. L. OLDIGS. *Arch. Suikerind.* **36**, 477–98 (1928); cf. *C. A.* **21**, 2571.—A discussion of the advantages of electrification, and a description of the installation at Wonopringo, Java. P. R. PEKELHARING

Drying of sugar products and determination of moisture. D. SIDERSKY. *Bull. assoc. chim. sucr. dist.* **45**, 247–9(1928).—Heating of samples in a capsule inserted in a tube through which dry air was passed and to which a $CaCl_2$ tube was attached showed that at 108° const. weight both of sample and of $CaCl_2$ tube could be attained in 2 hrs. with first-product beet sugars. With second and lower beet products the $CaCl_2$ tube reached const. weight in $2^1/_2$–3 hrs., but the samples underwent a slight further loss (about 0.1%) during the next hour. With raw cane sugars, constancy of weight could not be reached even in 6 hrs., probably because of slow decompn. of levulose. For exact detns. of moisture heating *in vacuo* below 95° is recommended, although the ordinary method serves well enough for com. analyses. B. C. A.

Seed cane. P. DE SORNAY. *Rev. agr. Maurice* **5**, 109–11(1928).—A plea is made for the use of sound cane tops, preferably from plant cane, carefully selected, and given a warm water treatment. They should be planted as soon as possible after being cut.
F. W. ZERBAN

Progress in the beet-sugar industry since 1924. O. SPENGLER. Inst. für Zucker-Ind., Berlin. *Z. angew. Chem.* **41**, 194–200(1928). E. H.

Accurate determination of dry substance in beet house sirup. R. J. BROWN, J. E. SHARP AND A. R. NEES. *Ind. Eng. Chem.* **20**, 945–8(1928).—Digest clean sea sand that will pass a 40-mesh but not a 60-mesh sieve in strong HCl, wash free from acid, dry and ignite. Place 25 to 30 g. of the sand in an Al dish with a short stirring rod and a cover. The dish is 50 mm. diam. by 35 mm. high. Stir into the sand about 0.5 g. powd. graphite free from oil. Dry the dish in an oven overnight, cool in a desiccator and weigh. Weigh into the dish from a weighing buret an amt. of sirup contg. from 0.5 to 0.7 g. dry substance. Mix the contents of the dish thoroughly and place in a vacuum oven which permits no appreciable air leak. Dry at 90° and at a pressure of 125 mm. or less in an atm. of dried CO_2, feeding about 3 or 4 cu. ft., at atm. pressure, per hr. to the oven. Heat the samples for 72 hrs. or more; remove from the oven, transferring the dishes quickly to individual desiccators contg. fresh P_2O_5; allow to stand in the desiccators 3 days or more, and weigh rapidly after removing from the desiccator. Exptl. evidence is presented for the necessity of each step adopted in the procedure. The max. difference between duplicate detns. was 0.06% on sirup. The method is applicable to all beet house products including those contg. raffinose, but it is not advocated for other than beet products. F. W. ZERBAN

Copper-reducing substances contained in beet roots and diffusion juice. L. BRANCOURT. *Bull. assoc chim. sucr. dist.* **45**, 251–4(1928).—In diffusion juice from beets which have been stored or slightly injured by frost or other influences, the Cu reducing power is not a sure measure of the invert-sugar content. Decompn. of cellulosic and protein constituents of the beets is liable to occur, especially in the last units of the diffusion battery, and give rise to reducing substances without a corresponding disappearance of sucrose. These reducing substances differ from invert sugar in that, with proper treatment of the juice, they are not so liable as the latter to give rise to colored substances on liming and evapn. In badly frozen beets the decompns. which set in after thawing result in the formation of viscous products. Reducing substances are then apt to occur in widely varying amts., and on liming they yield sol. Ca compds. The ppt. formed on carbonatation is thereby reduced in amount and of a character difficult to filter even when considerable amts. of Na_2CO_3 are used. In such cases the author recommends heating the juice to actual boiling, at least after the first carbonatation, and adding a granular form of $CaCO_3$ to assist filtration. B. C. A.

The development of the alkaline defecation-carbonatation process. Clarification tests by the Chemical Section of the Experiment Station (Java), in the years 1925 and 1926. K. DOUWES DEKKER AND P. C. NICOLA. *Arch. Suikerind.* **36**, III; *Mededeel. Proefstat. Java-Suikerind.* **1928**, 721–49.—An historical survey is given of the expts. made to find a clarification process better than sulfitation and cheaper than carbonatation. The new method was to be based on the theory of Van Nes, that the main point in clarification is the formation of a gel of silicic acid and calcium silicate, and that the effect of p_H and of the adsorptive power of $CaCO_3$ is secondary. The expts. were made partly at Djatiroto on a semitechnical scale, and partly at Gesiekan, where a regular installation was built. The 1st series of expts. at Djatiroto was made with freshly pptd. $CaCO_3$ prepd. outside of the juice. The raw juice was limed to phenol-

phthalein neutrality and heated to boiling. After cooling, milk of lime and freshly pptd. $CaCO_3$ were added and the juice was filtered. Though the increase in purity was satisfactory and the lime content of the juice low, the filtration rates were unsatisfactory. The object of the 2nd series of expts. was to show that a heavy ppt. of $CaCO_3$ must be formed in the juice to perform the dehydration of the gel. Therefore a large quantity of CO_2 had to be accumulated in the juice before lime was added. The best way to obtain this was to add lime to alky., then to carbonate to p_H 6.7 to form bicarbonate, and finally to lime to p_H 8.4 to form carbonate. The lab. expts. were carried out with pure CO_2, the semitechnical expts. with flue gases, but without satisfactory results. For the technical expts. at Gesiekan a special installation was built to prep. 100% CO_2. The tests at Gesiekan had to be stopped on account of technical difficulties, but will be continued during the 1928 campaign. So far nothing definite can be said regarding the effect of SiO_2 in clarification. The method used at Gesiekan was as follows. The cold juice was limed to phenolphthalein alky., then carbonated with pure CO_2 to an acidity of 1000 mg. CaO per l. To this liquid of 6.7 p_H contg. the lime as bicarbonate the main quantity of the lime was added, and $CaCO_3$ pptd.; the final alky. was 700–800 mg. CaO per l. After settling and decanting, the clear juice and mud were satd. with CO_2 and the clear juice was filtered. The mud after heating to 70° was allowed to settle for a 2nd time. The mud from this settling was heated to 90°, filtered, and the filtrate together with the 2nd clear juice was added to the acid juice just before the main quantity of the lime was added. P. R. PEKELHARING

Dextrose determination with alkaline iodine solution. K. DOUWES DEKKER. *Arch. Suikerind.* **36,** III; *Mededeel. Proefstat. Java-Suikerind.* **1928,** 699–720.—A practical method is sought for the detn. of dextrose in solns. contg. sucrose and reducing sugars, in order to det. the proportion between dextrose and levulose. A critical review of the different methods based on the alk. iodometric detn. of dextrose is given The modification by Auerbach and Bodländer (*C. A.* **18,** 800) of Romijn's method seems to be the most practical, but the amt. of I had to be increased. A series of expts. was made to study the time of the reaction, the alky., and the I concn. necessary. As pure dextrose was not available, the expts. were made with invert sugar prepd. according to the method of the A. O. A. C. The following method was finally adopted. Place 25 cc. of the soln. to be analyzed and contg. approx. 30 mg. of dextrose in a glass-stoppered Erlenmeyer flask. Add 10–15 cc. (0.33 to 0.5 of the mg. dextrose present) of 0.1 *N* I soln., and then 100 cc. of a buffer soln. contg. 14.7 g. $NaHCO_3$ and 2.95 g. Na_2CO_3 (93%) per l. Stopper the flask and put it in a dark place for 40 min. Acidify with 12–15 cc. 25% H_2SO_4 (1 part concd. acid and 5 parts H_2O), and titrate with 0.1 *N* $Na_2S_2O_3$ soln. Run a blank test with 25 cc. of H_2O and apply the correction. One cc. of 0.1 *N* I soln. is equiv. to 9.005 mg. dextrose. The results obtained with invert sugar are about 1.8% too high, and a correction may be applied for this if desired Another series of expts. was made to investigate the effect of sucrose on the detn of the dextrose. The best results were obtained at the same alky. as in the 1st series The reducing power of sucrose is 0.25% of that of dextrose. Therefore the limit of permissible sucrose concn. is fixed by the required accuracy of the result. The possible application of this method to factory products will be investigated. P. R. P.

Decomposition of sucrose by adsorbent carbons. E. LANDT. *Z. Ver. deut Zukerind.* **1927,** 834–40.—A mathematical exposition of Vasátko's results (*C. A.* **22,** 2287). H. G.

Some adsorption properties of bone char. T. B. WAYNE. *Ind. Eng. Chem.* **20,** 933–40(1928).—Elaborate expts. have shown that a layer of alk. substances adsorbed by char plays an important part in the removal of ash from sugar liquors, entirely apart from the effect of the mineral skeleton of the char itself. In actual refining practice ash adsorption may be increased by revivifying the char at the highest possible temp which avoids a p_H high enough to decrease decolorization materially or to produce darkening of the liquor. In any attempt to evaluate the ash-adsorbing qualities of chars it is necessary to consider the p_H of the char and of the liquor. At the beginning of a char filter cycle considerable invert sugar disappears, either actually or apparently, but a part of it is again released upon sweetening off. F. W. ZERBAN

The beginning of the mutual factory control in Java. H. C. PRINSEN GEERLIGS *Arch. Suikerind.* **36,** 613–21(1928).—Historical. P. R. PEKELHARING

Extracting and purifying saccharine juices. K. Komers and K. Cuker. Brit. 283,564, Jan. 14, 1927. Beet slices or like materials from which juices are to be extd. by lixiviation are preliminarily treated with finely divided substances such as active C, pulverized coke, cellulose, hydrocellulose, metals, metal oxides or salts to increase their active adsorption surfaces in contact with the crystalloid soln. to be purified. An app. is described.

Purification of crude sugar juice with lime and sulfurous acid. Johannes Manschot and Willem Appel. Dutch 18,227, July 16, 1928. The process is an improvement of the hot sulfitation process for cane juice. Sufficient acid juice is run into a vessel with milk of lime to make it weakly acid or neutral. It is then heated to 80° (physical purification) and transferred to a cylindrical vessel, where SO_2 can be passed through it from the bottom center, inducing juice circulation up through an axial pipe open on both ends inside the cylinder. More lime is added in the outside space so as to give difference in reaction (weakly alk. and acid) simultaneously in different parts of the cylinder (chem. purification). The end result is an acid juice of 120 mg. SO_2 per l. of good clarity and easily filterable.

29—LEATHER AND GLUE

ALLEN ROGERS

Progress in the field of tanning chemistry and technic. O. Gerngross. Techn. Hochschule, Charlottenburg. *Z. angew. Chem.* **41,** 221–6, 254–62(1928). E. H.

Value as a tanning material of the bark of "Cay-Duoc-Sanh" of Cochin China. F. Heim de Balsac. *Halle aux cuirs* **1928,** 217–53.—This bark, variously identified as *Rhizophora mucronata* Lamk or *R. conjugata* L., is readily extractable, and gives an easily filtrable ext., which produces satisfactory leather. Analysis of the bark showed: H_2O 13.9, insol. matter 58.7, tannin = 16.4, and non-tannin = 11.0%. Because of the relatively low tannin content and the relatively high proportion of non-tans, this species has less possibilities than other similar plants. H. B. Merrill

Chrome tanning. IX. 6. A bibliography of chrome tanning. Donald Burton. *J. Intern. Soc. Leather Trades Chem.* **12,** 337–42(1928); cf. *C. A.* **21,** 1028. H. B. M.

Tanning products derived from the manufacture of wood cellulose. René Escourrou. *Halle aux Cuirs* **1928,** 203–14, 234–46; cf. *C. A.* **22,** 4002.—Sulfite cellulose liquors are treated by 1 of a no. of enumerated processes, and evapd. either to dryness or to a thick sirup. The resulting ext. contains lignosulfonic acids, akin to syntans; they resemble syntans in properties and uses. Analyses of 3 solid and 13 liquid exts. are given. In addn. to insol. matter, sol. matter, non-tans and tans, important characteristics are titrable acidity, p_H value and ash. Ash in samples analyzed varied from 1.5 to 14.2%, according to completeness of elimination of CaO from sulfite liquor. High ash is objectionable. Slight acidity is desirable, but the presence of free H_2SO_4 or HCl is objectionable. Fluorescence of sulfite cellulose tanning exts., which resembles that of syntans, is too variable to be used as a qual. means of detection. Uses: (1) To aid in dissolving such natural tanning materials as quebracho. (2) In tanning, mixed with natural tanning materials, to obtain quicker penetration, cleaner liquors, brighter colored leather and higher yield. (3) In retanning, mixed with natural tanning materials, to obtain a firmer leather. Mixts. of sulfite cellulose ext. with syntans are in themselves satisfactory tanning materials, neither of which is satisfactory alone. The employment of sulfite cellulose is desirable as a means of conserving vanishing natural tanning materials. H. B. Merrill

Fractional salting out of vegetable tan liquors. N. Kotelnikov and I. Bass. *Vestnik* (Organ of the All-Russian Leather Synd.) **1927,** 57–8; *Collegium* **1928,** 366.—The coagulation of tannin by salt is reversible. The existence of the sol state is detd. not by the ratio of electrolyte to dispersed material but by the concn. of electrolyte in the soln. Analyses of cold- and of hot-extd. badan liquors showed no difference in tannin concn., but the cold-extd. liquor contained more material non-precipitable by NaCl, and is therefore better adapted to the first stages of tanning. H. B. Merrill

Nature and prevention of salt stains. I. Kaplan and M. Luxemburg. *Vestnik* (Organ of the All-Russian Leather Synd.) 1927, 58–60; *Collegium* 1928, 428.—A review.

Application of scientific principles to the soaking of hides. Frederick L. Hilbert. *Hide & Leather* 74, No. 11, 30–1(1927), *et seq.*—A discussion. H. B. Merrill

Storage of raw hides. I. Lokshin and M. Luxemburg. *Vestnik* (Organ of the All-Russian Leather Synd.) 1927, 236–9; *Collegium* 1928, 428–9.—Methods of handling skins in proposed central storage houses are described. Skins as received are (1) drained 2 hrs., (2) washed in a drum and again drained, (3) brined for 10 days, and (4) piled in packs of 250 heavy or 2000 light pieces. H. B. Merrill

Raw skin damage. A. Dyakov and M. Luxemburg. *Vestnik* (Organ of the All-Russian Leather Synd.) 1927, 240–4; *Collegium* 1928, 429.—The center splits from heavy calf skins showed holes of various sizes, although the grains and fleshes were not damaged. The damage is detectable after unharing, in the form of red spots, visible by transmitted light, from which a yellow liquor can be expressed. The trouble is attributed to autolysis during storage, and is said not to be of bacterial origin.
H. B. Merrill

Raw skin damage. A. Shcherbak. *Vestnik* (Organ of the All-Russian Leather Synd.) 1927, 290; *Collegium* 1928, 430; cf. preceding abstr.—Damage similar to that above described was noted in tanning with exhausted and foul liquors during a tannin shortage. The trouble was stopped by disinfection of vats and employment of sufficient strong ext. H. B. Merrill

Depilation of skins by means of alkaline solutions. Robert H. Marriott. Brit. Leather Manuf. Research Assocn., London, Eng. *J. Intern. Soc. Leather Trades Chem.* 12, 216–34, 281–303, 342–60(1928).—The theory is maintained that unhairing is brought about by 2 purely chem. reactions: (1) hydrolytic breaking down of keratin, catalyzed by OH, and (2) action of reducing agents on cystine group, rendering keratin sol. This reduction takes place only at $p_H > 11$. Unhairing expts. with dried goat skin showed that addn. of KCN, Na_2SO_3 or $FeSO_4$ to satd. $Ca(OH)_2$ soln. contg. excess solid $Ca(OH)_2$ accelerated unhairing. Slight acceleration was noted in old limes contg. reducing substances derived from skin or hair, and in air-free limes, as compared to ordinary $Ca(OH)_2$ solns. KCN has a sharpening action about equal to Na_2S. Sharpening action of Na_2SO_3 is partly due to increased OH concn. Addn. of $Fe_2(SO_4)_3$ or $K_2S_2O_8$ to lime inhibits unhairing. Addn. of KCN or Na_2SO_3 to dil. NaOH gave solns. of enhanced depilatory power. Hair soaked in these solns. gave a pink test for —SH with nitroprusside, indicating reduction of cystine to cysteine. Previous soaking of dried goat skin in dil. NaOH + Na_2SO_3 accelerates subsequent unhairing in $Ca(OH)_2$, but only if p_H of soak > 11. Action of OH on hair was studied by soaking human hair in borate-NaOH buffers of p_H = 8–13 for 2, 5 and 7 days, and detg. dissolved N. p_H value has practically no effect up to p_H = 11–12, above which hydrolysis of hair is noticeably increased. Making liquor 0.1 *N* in Na_2SO_3 had no effect on N dissolved up to p_H = 11. Hair previously soaked in these alk. solns. was treated with approx. 0.25% Na_2S for 20 hrs., and dissolved N detd. Hair pretreated at $p_H > 11$ is less acted on by Na_2S than hair pretreated below p_H = 11, because of previous destruction of the —S—S— group by alkali. Pretreatment of hair with Na_2SO_3 had no effect on subsequent action of Na_2S. Solns. of cystine are fairly rapidly decompd. by $Ca(OH)_2$, as demonstrated by formation of NH_3. Na_2S retards decompn. of cystine to NH_3 by lime. Gelatin is only slowly decompd. to NH_3 by lime; and the presence of Na_2S does not affect reaction. Most of the NH_3 found in lime liquors is probably formed from cystine. Presence of cystine in lime liquor accelerates the decompn. of gelatin slightly, and the presence of both cystine and Na_2S accelerates decompn. of gelatin markedly. Cysteine is more rapidly broken down by lime than is cystine. Action of different alkalies at the same concn. on cystine is not the same. $Ca(OH)_2$ has greater action than any other alkali, including $Ba(OH)_2$ and $Sr(OH)_2$. Hydrolysis of collagen was studied by treating purified ox corium with various alk. solns. at 22–23°, and detg. (1) free NH_3, (2) total dissolved N after 14, 28, 56 and 112 days. Most of the NH_3 formed is liberated at the outset, while total N increases linearly after initial rapid increase, probably because of soln. of easily hydrolyzed material. Hair is more completely decompd. by $Ca(OH)_2$ alone than is collagen for any given digestion period. Addn. of hair and of cystine to the system: collagen - $Ca(OH)_2$ did not increase decompn. of collagen. Na_2S had less action on collagen than $Ca(OH)_2$. The enhanced depilatory power of old limes is ascribed to reducing substances formed by action of liquor on skins previously passed through it. The mol. mechanism of the action of sulfides and of alkalies on cystine is discussed. H. B. Merrill

The hydrolysis of leather. G. Arbuzov. All-Russian Leather Synd. Expt. Sta.,

Vestnik (Organ of the All-Russian Leather Synd.) **1927,** 337–42; *Collegium* **1928,** 365–6; cf. *C. A.* **22,** 2486.—Three sole leathers tanned, resp., with oak, quebracho and oak-quebracho mixts., were investigated. Samples were hydrolyzed by continuous and intermittent heating on the water bath. Conclusions: (1) Leather is a system not in equil. (2) During hydrolysis, especially in leathers not uniformly tanned, there takes place a rearrangement of uncombined or loosely combined tannin, resulting in an equil. between the solid and liquid phases. (3) In the equil. state brought about by hydrolysis a chem. compd. exists. The equil. relationships between protein and tannin are different for different tanning materials. (4) In treating leather with MeOH, some replacement of tannin by alc. may occur. (5) Previous treatment of leather by alc. does not change the wt. relationships between hide substance and tannin existing in the hydrolysis products. Upper leathers gave hydrolysis products of const. compn. independent of duration and method of hydrolysis, but different from the hydrolysis products of sole leather. [Note: Data on which these conclusions are based are not available to the abstractor.] H. B. MERRILL

Indigosol dyeing and printing of hides. J. S. TURSKI AND J. ROSENZWEIG. *Przemysl Chem.* **12,** 173–5(1928).—Hides dyed or printed with indigosols retain their colors in light, sweat, water, rain or mud. Indigosols cause no weakening of the leather. In view of their color-fastness and the superiority of the colors indigosols should prove widely serviceable, and their cost should not prove an important impediment to development of their use. A. C. ZACHLIN

Efficiency of a tannery-waste-treatment works (SCHAETZLE, BLOHM) **14.** Water-soluble dyes [for leather] (U. S. pat. 1,684,330) **25.** Detergents [for use in the leather industry] (Brit. pat. 283,786) **27.** Derivative from ligninsulfonic acid (Can. pat. 282,677) **23.** Tanning agent from sulfite cellulose waste liquor (Ger. pat. 451,913) **23.** Waterproofing paste [for use on leather] (U. S. pat. 1,684,086) **26.**

Tanning skins and hides. JOHANNES HELL. Ger. 451,988, Oct. 31, 1927. One hundred kg. of hides is treated with 12 kg. of $CaCl_2$ and 5–6 kg. of $CaCO_3$. During the tanning 0.1 kg. of quinone is gradually added. The treatment is allowed to run for 20 hrs. The $CaCl_2$ can be replaced with 15 kg. of $MgSO_4$ and the quinone replaced with 0.6 kg. of formaldehyde. $MgCl_2$ may be also used instead of $MgSO_4$.

Repairing cracked patent leather. J. J. NESTOR. Brit. 283,995, Oct. 16, 1926. The surface layer of the cracked portion is removed, a filler such as a mixt. of shellac, gum benzoin, MeOH or EtOH, poppy oil and coloring matter (or a mixt. which may be formed of carnauba wax with shellac wax, paraffin, ceresin and stearic acid) is applied, and a shellac or copal varnish or the like is then applied and the solvent evapd. by a blast of air. Nitrocellulose also may be used.

Cleaning leather goods and furs. ACHILLE SERRE, LTD., AND J. B. ARGENT. Brit 283,709, Dec. 11, 1926. The articles are tumbled in a rotating drum (of special construction, which is described) with hardwood sawdust or a mixt. of fine sand and wood dust to which may be added a small proportion of a non-inflammable solvent.

Glue or gelatin. JOSEPH C. KERNOT. Ger. 451,985, Nov. 21, 1927. Refuse, such as the skin, head, tail and bones of the fish, after washing with water is given repeated treatment with weak alkali or alkaline reacting salts. After again washing with water the refuse is treated with dil. acid, preferably H_2SO_4. It is again washed with water. The liquor resulting is concd. and allowed to solidify. The gelatin is cut into pieces and dried.

30—RUBBER AND ALLIED SUBSTANCES

C. C. DAVIS

The thermochemistry of rubber. SIEGFRIED BOSTRÖM. Univ. Giessen. *Kolloidchem. Beihefte* **26,** 439–70(1928).—The work consists of 3 parts: (1) the development of a method for detg. the "activity" of technical pigments and filler; (2) the thermodynamics of the Joule effect in rubber and (3) an investigation of the thermochemistry

of the vulcanization process. The "activity" of fillers, *i. e.*, their so-called reinforcing effect, was detd. indirectly by measuring 3 heat effects: (1) the heat of swelling of rubber in C_6H_6; (2) the heat of wetting of the powder by C_6H_6 and (3) the energy represented in the adhesion of filler and rubber. The energy was then calcd. on a basis of 1 g. of C black from the difference between (1) and the sum of (2) and (3). The values of (3) for different fillers is considered to be a criterion of their "activity," particularly since the actual results obtained conform to the relative effects obtained by Wiegand in a quite different way (cf. *C. A.* 14, 2732). Preliminary tests showed that the heat of wetting of C blacks increases with their sp. surface. In studying the thermodynamics of the Joule effect, the change in total energy, the work of extension and the temp. coeff. of the mech. work were detd. The heat tone was directly proportional to the elongation, lending support to the theory that the Joule effect depends upon a fiber structure. From the point of view of the Hock theory (cf. *C. A.* 21, 4092) the Joule heat of elongation is proportional to the no. of aligned and packed particles. The sp. heat of raw rubber, detd. by 3 different methods, averaged 0.37 at 17° and the temp. coeffs. of mech. work involved in stretching to 250, 500 and 800% elongation were —0.002, —0.0024 and —0.0035 cal. per degree C. The heat tone of the reaction between S_2Cl_2 and rubber dissolved in benzine was measured through a range of concn. of 0–1.3 g. of S_2Cl_2 per g. of rubber, but no definite conclusion could be drawn as to whether adsorption or chem. combination was involved. The app., which comprised a specially constructed *calorimeter*, and the technic are described in detail and illustrated. C. C. DAVIS

Rubber in the printing industry. D. R. SCHLITZ. Goodyear Tire & Rubber Co. *Rubber Age* (N. Y.) 23, 619–20(1928).—An illustrated description. C. C. DAVIS

Evaluation of variable temperature cures. J. R. SHEPPARD AND W. B. WIEGAND. Eagle-Picher Lead Co., Joplin, Mo. and Binney & Smith Co., New York. *Ind. Eng. Chem.* 20, 953–9(1928).—Utilizing the generally accepted empirical rule that the intensity of the curing action becomes twice as great for each 15° F. rise of temp., formulas are derived to show the relations between the several variables of a cure segment with a const. temp. gradient, *viz.*, the intensity of curing action, the curing effect, the time and the temp., on the one hand and the consts. of such a cure, *viz.*, the initial temp and the temp. gradient, on the other hand. An exact valuation of cures is applied to schedules with variable temps. by the use of the equations showing the curing effect as a function of the other characteristics of the cure. These equations are the most important ones in practice. The curing effect, which measures the net value of a schedule in effecting vulcanization, can be detd. for a given schedule by calcn. from one of the "effect" equations, by reading directly from graphs which are given, or by estg. the area under an intensity-time curve. The intensity of curing action is a measure of the importance of a temp. in inducing vulcanization, and the intensity-time curve shows the curing ability of the various parts of a schedule even more accurately than the more usual temp.-time curve. Examples of the application of the method to typical factory cures are given. C. C. DAVIS

Chromolited rubber molds. F. E. RICHARDSON. Nat. Chromium Corp. *Rubber Age* (N. Y.) 23, 607–8(1928).—When molds are properly plated with Cr, there is less sticking of the rubber than to other metals because of the unusual resistance to heat and to attack by acids and gases. C. C. DAVIS

The use of mineral oil with a favorable customs duty in the rubber industry. PAUL ALEXANDER. *Gummi-Ztg.* 42, 2410–1(1928).—A discussion dealing with the definition of *solvent for rubber*. C. C. DAVIS

Rubber compression testing machine. C. L. HIPPENSTEEL. Bell Telephone Labs. *India Rubber World* 78, 55–6(1928).—See *C. A.* 22, 2855. C. C. DAVIS

Abrasion tests of rubber stocks containing various types of carbon black. W. B. PLUMMER AND D. J. BEAVER. *Ind. Eng. Chem.* 20, 895–9(1928).—On a slightly modified Williams abrasion machine (cf. *C. A.* 21, 2573) the resistance to abrasion of rubber mixts. contg. different types of C black decreased with increase of the particle size of the abrasive up to 0.45 mm., above which the resistance to abrasion increased. No explanation is offered. Rubber mixts. were then alternately abraided and aged in air at 70° so that only the surface which had deteriorated was worn away. In this way an indication was obtained of the resistance to abrasion of the mixts. under conditions more nearly approaching service conditions, where abrasion and aging progress simultaneously. Some types of C black increased the rate of deterioration much more than did other types, as a result of which the relative resistances to abrasion of mixts. contg. different C blacks changed as aging progressed, in fact the resistance to abrasion of the surface layers of one mixt. may be greater than that of another mixt. before aging but may become less than that of the other after aging. This shows that the value

of a C black must be judged not only by the resistance to abrasion but also by the aging properties which it imparts to rubber. Where the wear is slight compared with the deterioration, the aging imparted by a C black is a determinant factor in the life of a tire. C. C. Davis

Carbon black. I. A study of its volatile constituents. C. R. Johnson. G. L. Cabot, Inc., Boston. *Ind. Eng. Chem.* **20**, 904–8(1928).—Complete analyses were made of 5 types of C blacks, before and after evacuation, and of the gases removed, and a C balance was detd. with the object of correlating the proportion and compn. of the volatile components and the properties imparted to vulcanized rubber mixts. by the blacks. The results show that within certain limits the volatile matter in a C black has no determinant effect on the properties imparted to rubber, but that above certain limits it reduces the reënforcing power of the C black and retards the rate of vulcanization. This undesirable limit is fairly const. for each grade of C black, but the limits vary among different blacks. The gases extd. from the C blacks contained CO, CO_2, H, N, CH_4, C_2H_6, illuminants and O. It is probable that the CO and CO_2 were reaction products of the O originally present. C. C. Davis

Legal specifications concerning the color of rubber goods. A. Beythien. *Gummi-Ztg.* **42**, 2464–5(1928).—Of special concern to German industry. C. C. Davis

The influence of Vulkan colors on the aging of rubber articles. Rudolf Ditmar. Kautschuklaboratorium, Graz. *Gummi-Ztg.* **42**, 2519(1928).—A large no. of "Vulkan" colors were tested in the 2 different base mixts. to det. the influence of the individual colors on the aging of the mixt. Some of the colors caused abnormally rapid deterioration, whereas others had a distinctly preservative effect. Whether the color had a good or a bad effect depended in turn upon the type of rubber mix. C. C. Davis

A scheme of accelerator classification. R. P. Dinsmore and W. W. Vogt. *Trans. Inst. Rubber Industry* **4**, 85–106(1928).—A survey and crit. discussion of the *characteristics of org. accelerators*, which for convenience may be divided into several groups: (1) dithiocarbamates; (2) xanthates; (3) thiuram mono- and disulfides; (4) mercaptobenzothiazoles; (5) aldehyde-amines; (6) ethylideneanilines; (7) guanidines; (8) thioureas, and (9) individual cases, such as *p*-nitrosodimethylaniline, aldehyde-ammonia, hexamethylenetetramine and the CS_2 reaction product of butyraldehydeaniline, of which other accelerators of the same types are not known. Summarized data show the general characteristics of these groups, including their *relative activity and characteristics during manufacturing processes*, their *S requirements*, the *phys. properties which they impart to vulcanizates*, their *stability during vulcanization*, their *antioxidant properties* and their *stearic acid requirements*. The chem. compns. of 46 com. accelerators are also tabulated. In manufacturing, accelerators should be judged by (1) their activity; (2) their ability to disperse and to soften rubber mixts. and not cause scorching; (3) their stability in uncured mixts.; (4) the S requirements; (5) the necessity for stearic acid; (6) their adaptability to air, steam and press curing; (7) their stability during vulcanization; (8) the stiffness and tensile properties imparted to rubber mixts. with and without pigments; (9) their antioxidant power and (10) the changes such as stiffening in vulcanizates contg. the accelerators. These criteria are discussed individually, in some cases with the inclusion of new data. A study of the *difference between tearing by hand and max. tensile product as a criterion of proper cures* showed that with mixts. contg. no pigments and particularly when unaccelerated, there is a big difference between the optimum cures, tearing by hand indicating a shorter cure than max. tensile product. With loaded mixts. these differences become relatively small. The max. resistance to tearing by hand is claimed to coincide in all cases with the cure which ages best. The *rate of oxidation of a rubber mixt. during natural or artificial aging* increases progressively with the time of vulcanization and bears no relation to the flatness of the tensile strength-time of vulcanization curve, so that constancy of tensile strength over a range of time of vulcanization is useless in judging the aging properties imparted by an accelerator to a rubber mixt. The *tendency of a rubber-mixt. to scorch* may be judged by heating for definite periods at 70° or 100° and detg. the plasticity and recovery in a Williams plastimeter before and after such heating. *Stiffening during aging* is not necessarily accompanied by an increase in combined S, and may be simulated artificially by heating rubber mixts. at 70° in an inert gas. Numerous examples are cited to show the behavior of some of the more important individual accelerators. A general discussion follows the paper. Also in *Rubber Age* (N. Y.) **23**, 554–7(1928). C. C. Davis

Watch case vulcanizers. Joseph Rossman. *India Rubber World* **78**, 69–71 (1928).—A chronological review of the patent literature. C. C. Davis

The negative catalysis of autoxidation. Antioxygenic activity (Moureu, Dufraisse) 2. Lead compounds and magnesia (Norris) 18.

STEVENS, H. P.: **Latex.** London: Rubber Growers' Assoc., Inc. 66 pp.

Rubber. WILLIS A. BOUGHTON. Can. 283,464, Sept. 25, 1928. A soln. of ammonium polysulfide is made to react with latex, the liquid is evapd. and the residue heated and vulcanized.

Rubber composition. CHARLES H. CAMPBELL (to American Glue Co.). U. S. 1,683,862, Sept. 11. Sol. and diffusible cleavage products obtained by the hydrolytic decompn. of collagen (short of amino acids) are mixed with rubber. U. S. 1,683,863 specifies the use of products similarly obtained from keratin and U. S. 1,683,864 relates to similar compns. also contg. glue.

Synthetic rubber. I. G. FARBENIND. A.-G. Brit. 283,840, Jan. 14, 1927. Hydrocarbons suitable for manuf. of synthetic rubber such as butadiene, isoprene and dimethylbutadiene are emulsified (*e. g.*, with water and soap and egg albumin or with Na isobutylnaphthalenesulfonate) and then polymerized in the presence of O or substances such as a perborate or percarbonate which yield O.

Synthetic rubber. I. G. FARBENIND. A.-G. Brit. 283,841, Jan. 15, 1927. Polymerization of hydrocarbons such as butadiene, isoprene or dimethylbutadiene is effected by treatment with an alkali metal such as Na or K, in an atm. of H, N or CO_2 and in the presence of an org. hydroxy compd. or ether of high mol. wt. such as glycerol, starch, cellulose, a cellulose ether or superficially oxidized rubber. Temps. of 40–60° are suitable for effecting the polymerization in various examples which are given.

Rubber from sprayed latex. DUNLOP RUBBER CO., LTD., AND D. F. TWISS. Brit. 283,984, Sept. 17, 1926. Latex or a similar aq. rubber dispersion (which may be mixed with various modifying agents) is sprayed in a damp unheated state upon the unheated surface of a mold or former.

Solvent and dispersing agents for rubber. EBERHARD MEYER. Ger. 463,290, July 5, 1928. Esters of tetrahydronaphthol, *e. g.*, tetrahydronaphthol acetate or naphthenate, are used as non-volatile solvents or dispersing agents for rubber.

Making laminated rubber tire tubes from sheet material. ALBERT E. HENDERSON. U. S. 1,683,669, Sept. 11. Mech. features.

Coating metals with rubber. F. AHRENS. Brit. 283,049, April 16, 1927. Rubber coatings are attached to metals by use of a rubber soln. contg. S chloride or other suitable acid substance which attacks the metal and facilitates the formation of metal sulfide which assists in bonding of the metal and rubber. Oils such as a mixt. of rape and linseed oils also may be added to the rubber soln. Cf. *C. A.* **22**, 3806.

Porous rubber. H. ZIEGNER. Brit. 283,566, Jan. 14, 1927. A porous material such as wood sawdust is first satd. with a swelling medium such as benzine and then mixed with rubber compns. which may also contain fillers and vulcanizing reagents. The benzine or the like first causes the rubber to swell where it contacts with the added porous material and then during the drying operation to contract and become loosened from the sawdust or other added particles. The porosity may be further increased by adding water, which evaporates during vulcanization and enlarges the pores.

Rubber articles. ANODE RUBBER CO., LTD. Brit. 283,871, Jan. 18, 1927. The properties of articles made directly from rubber latex (suitably by electrophoresis or dipping) are modified by adding to the latex an artificially prepd. dispersion of coagulated rubber, gutta, balata or similar material. Various coloring, vulcanizing and modifying agents may also be added.

Rubber articles. DOUGLAS F. TWISS (to The Dunlop Rubber Co., Ltd.). Can. 283,262, Sept. 11, 1928. Articles of rubber are manufd. by treating the surface of a mold with a layer of jelly including a coagulant of the character of Na_2SiF_6, and dipping the mold into the material of which the article is to be formed.

Rubber heels. RICHARD F. KINSLEY (to Dryden Rubber Co.). U. S. 1,684,100, Sept. 11. In forming heels from ground waste vulcanized rubber, partially cured blanks of smaller area but greater thickness than the finished article are inserted in a mold, a layer of rubber material of greater plasticity and lesser elasticity than that of the blank is placed on the latter and the assembly is subjected to heat and pressure.

Vulcanization accelerator. W. J. KELLY. Brit. 283,679, Nov. 9, 1926. 1-Mercaptobenzothiazole, used as an accelerator, is made by heating to about 280° in an autoclave, $PhNH_2$, S and CS_2. The product is dissolved with NaOH and pptd. with HCl.

Vulcanization accelerator. L. B. SEBRELL. Brit. 283,661, Oct. 26, 1926. 1-Mercaptobenzothiazole, used as an accelerator, is made by heating under pressure a mixt. of NH_3 (as gas or aq. soln.), CS_2, $PhNH_2$ and S.

CHEMICAL ABSTRACTS

Vol. 22. NOVEMBER 20, 1928 No. 22

1—APPARATUS AND PLANT EQUIPMENT

W. L. BADGER

Instruments and apparatus. C. F. HIRSHFELD *et al.* *Mech. Eng.* **50,** 792–7 (1928).—A description of various types of gage *thermometers,* both indicating and recording, together with recommendations for their installation. T. S. CARSWELL

Laboratory mixing wheel or agitator. CLARK B. CARPENTER AND W. A. MANUEL. Colorado School of Mines. *Ind. Eng. Chem.* **20,** 1072(1928). E. H.

Specific gravity indicators. C. F. SPAULDING. *Eng. Mining J.* **126,** 499–500 (1928).—S. describes two float-type indicators, easily made in the mill, esp. for detg. pulp density. One is for use in tanks, the other in shallow launders. A. BUTTS

The pocket polarimeter of Leitz. K. SEILER. *Schweiz. Apoth. Ztg.* **66,** 181–2(1928); cf. *C. A.* **22,** 2203.—Report on an improved model (No. 253). The errors in detg. concns. of dextrose solns. (0.3–9.95%) vary within the narrow limits of +0.14 and −0.10%. S. WALDBOTT

Conductivity apparatus. JESSE E. DAY AND FORD C. DAVIS. Ohio State Univ. *J. Chem. Education* **5,** 1121–2(1928).—A simple, convenient and rather inexpensive cond. app. for first course chem. students is described. L. D. R.

Self-adjusting buret apparatus. ROBERT C. HOCKETT. Ohio State Univ. *J. Chem. Education* **5,** 1131–2(1928).—A very simple automatic buret is described. Opening the stopcock in the side arm of the buret automatically fills the buret to the zero mark. The glass work is extremely simple. L. D. R.

A new buret for volumetric analysis. N. M. KETOV. *Ann. inst. polytech. Oural* **6,** 355–7(1927).—For titrations with solns. easily decompd. while in contact with rubber or with stopcock grease, K. suggests a novel buret which ends at the bottom by an open narrow capillary and is closed at the top by a ground glass stopper provided with a capillary tubing and a stopcock. The flow of liquid can be regulated by opening or closing the stopcock. It is more convenient, however, to have the upper capillary connected with a tightly stoppered flask, through the stopper of which a second tubing is led and connected with an ordinary buret filled with water. The flow of liquid from the first buret is now regulated by admitting desired amts. of water from the second buret into the flask. G. B. KISTIAKOWSKY

A colorimeter without standard fluid (new model). A. ADLER. Univ. Leipzig. *Z. ges. exptl. Med.* **55,** 672–93(1927); cf. *Klin. Wochschr.* **1922,** 1492.—The colorimeter consists of an illuminating sphere contg. a 20 watt lamp, a holder for the soln. being studied, and a d. scale in the form of a disk. Projecting into the sphere is an eyepiece tube with an opening for placing various filters in the path. From a color chart and set of absorption curves the correct filter is selected for the soln. in question, and the transmission detd. by the use of the d. scale. F. L. DUNN

A simple colorimeter for determining iron and other components in water. F. MEINCK AND MARGARETE HORN. Landesanst. f. Wasser-, Boden- u. Lufthyg., Berlin-Dahlem. *Kl. Mitt. Ver. Wasserversorg. Abwasserbeseitig.* **2,** 130–5(1926); *Chem. Zentr.* **1927,** II, 1745.—With the new colorimeter 0.1 mg. of Fe, 0.1 mg. of NH_3 and 0.5 mg. of N_2O_3 per l. in 100 cc. of water can be detd. C. C. DAVIS

A modification of the Soxhlet extraction apparatus. N. SPASSKII. *Oel-Fett-Ind.* (Russia) **1927,** No. 3–4, 31–3; *Chem. Zentr.* **1927,** II, 1905.—The advantage of the new extn. app. constructed by S., which is illustrated, lies in the fact that the extn. can be carried out without heating. Furthermore it is cheaper and more durable than the regular Soxhlet app. It yields pure oil, so that filtration of the ext. is unnecessary. Losses of Et_2O are a min. C. C. DAVIS

Modified apparatus for determination of sulfur in iron and steel. M. H. STEINMETZ. *Ind. Eng. Chem.* **20,** 983(1928).—The app. consists of a special condenser attached to a Johnson S flask. The condenser is a Liebig condenser constructed so

that acid may be fed through a tube passing down the inner annular space, while the evolved H_2S passes between the condenser walls and the tube delivering the acid.

T. S. CARSWELL

Pyrometers for surface temperature measurements. ANON. *Indian Textile J.* **38,** 378–9(1928).—The Cambridge Instrument Co., London, has devised a new form of pyrometer which can be applied directly to the surface of such machines as calendering rolls, drying cylinders, vulcanizing presses, etc. The thermocouple consists of pieces of Cu and constantan (or other suitable metals) welded end to end and rolled out to form a continuous flexible strip with a smooth surface on both sides. The strip is supported, under spring tension, in a frame which forms a convenient handle. The hot junction is in the middle of the metal strip, so that when applied to the heated roller, a portion of the strip on either side is in direct contact with the surface to be measured. Several modifications of the strip thermocouple are described and illustrated. In one form, the thermocouple is attached directly to a millivoltmeter, calibrated in degrees, which is mounted on the back of the bow spring handle.

RUBY K. WORNER

A simple ultra-violet fluorophotometer. B. T. SQUIRES AND J. H. JEFFREE. *J. Sci. Instruments* **5,** 273–7(1928). E. J. C.

A microphotometer for the study of spectrograms. I. J. GWINN. State Univ. of Ia. *Proc. Iowa Acad. Sci.* **34,** 279(1927).—A modification of Harrison's microphotometer has been developed, following his suggestion, which is used for accurate measurements of line widths on spectrograms. A vertical optical system using microscope lenses focuses the light on a Bi-Ag thermocouple. Accurate readings of length are obtained with a finely constructed micrometer screw. Studies have also been made on the relative intensities of lines on both optical and x-ray spectrograms. The instrument is also of use in testing the uniformity of thin films of metal. W. G. GAESSLER

A new photogoniometer. ERICH HERLINGER. *Fortschritte Mineral. Kryst. Petrog.* **12,** 41–2(1927).—A brief description is given of a new photogoniometer for use in the study of crystals used in crystal structure detn. J. F. SCHAIRER

Universal x-ray photogoniometer. J. D. BERNAL. *J. Sci. Instruments* **5,** 241–50 (1928); cf. *C. A.* **21,** 3551.—B. describes and presents 8 illustrations of a photogoniometer made by W. G. Pye & Co., Cambridge, Eng. Its main features are: a clockwork motor which may drive the goniometer spindle directly through bevel wheels at a uniform velocity in one direction, or indirectly through a cam and lever arrangement which permits oscillations of the spindle; the fixed slide of the aperture carriage, which is mounted directly on the base; the aperture holder which can take either a slit system of vertical and horizontal adjustable slits, or an adjustable pin-hole system, or an ordinary optical collimator which is adjustable with regard to distance from the spindle axis; a swinging arm which supports the plate carriage slide; the plate carriage which can take several size plates or a telemicroscope and which also supports the cylindrical camera; the fixed circle which enables the positions of the crystal and plate to be detd.; and the gomiometer head which is of the usual type. The instrument may be used as an optical goniometer, or as an x-ray camera for taking Laue, spectroscopic, rotation and oscillation and Debye-Scherrer pictures. R. L. HERSHEY

A simple high-speed rotary pump. L. E. BAYLISS AND E. A. MÜLLER. Univ. College, Lond. *J. Sci. Instruments* **5,** 278–9(1928).—A small rotary pump is described, suitable for liquids or gases in which the fluid is forced through a rubber tube by the pressure of a series of rollers passing along it. Glycerol is used as a lubricant and the whole pump can be mounted in a glycerol bath. The output of such a pump in cc. per min. is a linear function of the speed up to about 1100 r.p.m. which corresponds to about 170 cc. per min. A pump with a rubber tube 7 mm. internal diam. gives about 12 l. per min. The rubber tubes must frequently be replaced after 24–36 hrs continuous operation. J. H. PERRY

A magnetically operated circulating pump for gases. FRANK ADCOCK. Nat. Phys. Lab. *J. Sci. Instruments* **5,** 290–2(1928).—A description of a simple form of gas circulating pump designed to avoid contaminating the gas with oil or air. Motion is imparted to an iron piston by supplying an interrupted current to a solenoid which surrounds the upper part of the pump barrel. H_2 has been circulated at rates up to 30 cu. ft. per hr. J. H. PERRY

Efficient stirrer for gas absorption. A. F. BENNING. Univ. of Notre Dame. *Proc. Indiana Acad. Sci.* **37,** 263–4(1927).—The object of the stirrer is to promote intimate contact between a gas and a liquid. Two short pieces of glass tube are sealed horizontally to the stirrer shaft, also of tube, so as to leave a short projection below the arms, *i. e.*, to form a 4-way piece The upper end of the tubular shaft is closed but

there is a small hole blown in any convenient spot of the lower part. The junction of the 4 tubes is constricted. On rotating the stirrer with the arms below the liquid the friction loss at the liquid entrance and the contraction reduces the pressure within the shaft and gas is drawn down to mix with the liquid. When the arms are just free of the liquid surface gas will be drawn down the hole and mixed with the liquid drawn up the shaft. A high revolving speed is necessary; hence couplings to the motive power should be flexible, pressure tubing and rubber stoppers being used.
S. L. B. ETHERTON

Gas generator. E. J. KRAUS. *Chem.-Ztg.* **52**, 711(1928).—The novel feature of this app. operating without valves is a glass rod which carries on its flattened end the perforated material (FeS, Zn, etc.). For interrupting the gas generation, the glass rod which is held in a rubber stopper, is pulled up, until the material is lifted above the surface of the acid. G. SCHWOCH

New apparatus for determining gas densities by Bunsen's flow principle. H. KAHLE. *Z. angew. Chem.* **41**, 876–80(1928).—Directions are given for operating 2 types of modified Bunsen app. in which the gas is passed back and forth through an orifice between 2 arms of the app. Results are given with air, N, O, H, CH_4, CO_2, He, Ne and A, with references. J. H. MOORE

Apparatus for sampling gases of sealed tins. C. H. F. FULLER. *J. Sci. Instruments* **5**, 259(1928).—A 7-mm. glass tube is tapered down to 2.5 mm. and fitted with a 2.5 mm. side tube. A steel needle tapered to fit the inside of the glass tube is placed inside the glass tube to which it is joined by a rubber cap, which seals off the space between the needle and tube. The base of the tube is fitted with a rubber suction cap which makes it possible tightly to attach the whole device to the can to be tested. The can is punctured by the needle and the gases are withdrawn through the side tube.
R. L. HERSHEY

A simple device for the measurement of light absorption. K. ŠANDERA. *Chem. obzor* **3**, 69–73(1928).—See *C. A.* **21**, 3492. JAROSLAV KUČERA

A simple extraction apparatus. I. YA. POSTOVSKII AND E. M. TITOV. *Ann. inst. polytechn. Oural* **6**, 359–60(1927).—An app. for extn. by means of heavy liquids, which can be easily constructed in a lab., is described. G. B. KISTIAKOWSKY

Use of the interferometer in scientific and technical work. E. BERL AND L. RANIS. Inst. Techn. Hochschule Darmstadt. *Fortschritte Chem., Physik physik. Chem.* **19**, 1–52(1928).—A comprehensive description of gas and liquid interferometers and their uses in phys. and chem. measurements. J. S. PERRY

The independent constructor in the chemical industry. HANS WOLLENBERG. *Chem. App.* **15**, 195(1928). J. H. MOORE

Determining the most favorable wall thickness of industrial furnaces. H. REPKY. *Arch. Wärmewirt.* **9**, 145–9(1928).—A mathematical discussion, especially of the case of intermittent use. ERNEST W. THIELE

The electric micro-combustion furnace of Heraeus. BONIFAZ FLASCHENTRÄGER. Univ. Leipzig. *Z. angew. Chem.* **41**, 840–1(1928).—Description, with directions for operating (cf. *C. A.* **20**, 2802). J. H. MOORE

Metal air heater for industrial furnaces. WALDEMAR DYRSSEN. *Iron Steel Eng.* **5**, 81–4(1928).—The materials which have been used in the construction of air preheaters for furnaces are discussed. Heat-resisting steels, such as high-Cr steels, seem to be most suited to this type of service. A few representative air heaters which are constructed of heat-resisting steel are described, and diagrams are given showing their construction. M. C. ROGERS

Heat and power plants. CHR. EBERLE. *Arch. Wärmewirt.* **9**, 41–5(1928).—Installations are described in which steam is generated at high pressure, and after furnishing power, is used as process or heating steam in textile plants and the like.
ERNEST W. THIELE

Long-distance heating and copper installation. ANON. *Apparatebau* **40**, 219–21 (1928).—The advantages of Cu over Fe are stressed. J. H. MOORE

Automatic regulation, especially for electric oven. ANON. *Chem.-Ztg.* **52**, 721 (1928).—The temp. is regulated by an adjustable contact thermometer which will work for temps. as low as 50–100°. J. H. MOORE

The mechanical chemist—another miracle of modern science. (Methane continuous recorder.) JOHN H. SCHALEK. *Natural Gas* **9**, No. 9, 26–7(1928).—An app. is described which will continuously analyze and permanently record the percentage of methane in air. The operation of the recorder may be described as follows: a small motor-driven pump draws the gas sample into the instrument. The sample first passes through a chem. absorber for removing water vapor and CO_2. The sample next passes

through an automatic flow regulator, where the correct predetd. const. vol. of sample is fed into the machine. It is then conducted through a silica or porcelain tube heated to about 800° by an elec. furnace. Here the methane is completely oxidized to CO_2 and water. These products are removed by a chem. absorber; as a result there is a contraction in the vol. of the sample equiv. to 3 times the vol. of the methane originally present. The remainder of the sample is led through a second flow meter equipped with a sensitive differential recorder. If no methane is present the vol. will remain const., and the head of pressure required to force it through the second orifice will be identical with that of the first orifice. If methane is present the pressure required to force the reduced vol. of the sample through the second orifice is correspondingly lower. This difference in pressure is recorded on a chart calibrated to read percentages of methane direct. The pen arm has a travel of nearly 4 in. for approx. 2% methane The machine is sensitive to less than 0.02% methane. This same principle can be applied to give a continuous record of such gases as O, CO and CO_2. E. G. M.

"Acid-alkalimeter"; a direct-reading p_H meter. KENNETH H. GOODE. *J. Optical Soc. Am.* **17**, 59–71(1928).—G. has used in a H-ion meter 3 tubes, with a milliammeter as indicating device. He has also described a two-tube instrument. Thoriated filament tubes have been abandoned for the oxide-coated type. In the second instrument the indicating device is a special Weston 3-terminal voltmeter-milliammeter. Diagrams of the circuits of the original, the 3-tube and the 2-tube simplified acid-alkalimeter are given. L. D. R.

Steel barrels and drums. R. M. HUDSON. Bur. of Standards. *Simplified Practice Recommendation* **R20-28,** 9 pp.(1928). E. J. C.

Electrodes for p_H determinations (FASOL) **7.** Pb as a constructional material for chemical plant (TUNGAY) **9.** Heat transfer data for the scrubber designer (ROSEBAUGH) **13.** Heat capacities of organic compounds at low temperatures. I. Precision calorimeter and thermostat for low temperatures (ANDREWS) **2.** Apparatus for gravity separation of ores or other materials (U. S. pat. 1,685,521) **13.**

Laboratory table. OLIVER G. HARNE. U. S. 1,686,234, Oct. 2. Structural features.

Apparatus for transferring measured small quantities of liquids for laboratory purposes. LEON H. CORNWALL and GEORGE P. SCHMITT. U. S. 1,687,007, Oct. 9.

Air washing apparatus. ALVIN H. COLBERT. U. S. 1,686,144, Oct. 2.

Water still. ERNON V. OLIVER. U. S. 1,686,418, Oct. 2.

Viscometer. JACQUES WOUDHUYSEN and GASTON ORY. U. S. 1,685,896, Oct. 2

Dewar flask. GISELA GRUNWALD. Austrian 108,989, Oct. 15, 1927. An adsorbent for air is arranged in the space between the walls.

"Bubble tower" for fractionations or use in other processes. LOUIS E. WINKLER and FRED C. KOCH. U. S. 1,686,542, Oct. 9. Structural features.

Regulating the temperature of catalytic converters, etc. C. E. ANDREWS (to Selden Co.). Brit. 285,499, Feb. 19, 1927. A two-phase liquid-vapor system such as an alloy of Cd and Hg is used with a reflux condenser and the b. p. of the system is varied by altering the compn. or the quantity of reflux condensate before returning it to the liquid phase in the system. An app. is described.

Filter. ETABLISSEMENTS SIMONETON (SOC. ANON. À RESPONSABILITÉ LIMITÉE). Fr. 633,782, May 3, 1927. Constructional details.

Filter and faucet construction. S. BARRAND. Brit. 285,334, Sept. 12, 1927.

Rotary drum apparatus for straining liquids. F. W. BRACKETT. Brit. 284,403, Oct. 28, 1926.

Rotary drum and travelling cloth belt filter and washing apparatus for treating liquids. D. STEWART & CO., LTD. (W. Mauss). Brit. 284,960, Sept. 24, 1927. Structural features.

Bag filter. FIRMA FRITZ SCHEIBLER. Fr. 635,462, June 2, 1927. The flow tubes of closed bag filters are connected to the taps by bayonet joints.

Filter press. LOUIS A. J. REVEL. Fr. 635,962, June 14, 1927.

Thermometer suitable for use on engines or other vibrating apparatus. EDWARD B. FOOTE (to Taylor Instrument Companies). U. S. 1,685,193, Sept. 25. Structural features.

Temperature alarm. ÖSTERREICHISCHE SIEMENS-SCHUCKERT-WERKE. Austrian 109,103, Nov. 15, 1927. Constructional details.

Temperature alarm sensitive to undue rise or unduly rapid rise of temperature. J. PICARD and A. TOURNADRE. Brit. 284,650, Feb. 2, 1927. Structural features.

Apparatus for the production of very high temperatures and pressures. GEORGES BOIVIN. Fr. 32,709, July 7, 1926. Addn. to 615,329. The protecting substance of the refractory material is in the form of an impalpable powder such as sandstone, alum or graphite compressed alone or with appropriate substances.

Heat-exchange apparatus formed with drilled or grooved metal blocks or plates. C. W. STANCLIFFE. Brit. 285,151, Nov. 11, 1926.

Acetylene generator. AUGUST VALENTOUR. U. S. 1,684,979, Sept. 18.

Acetylene generator. AUGUSTE F. GIRARDIN. Fr. 32,626, Nov. 12, 1925. Addn. to 554,247. Constructional details.

Acetylene generator. GAUDÉRIQUE A. D. MONA. Fr. 635,258, May 31, 1927. Means is provided for the automatic addition of CaC_2 as the amt. of gas decreases.

Acetylene generator. RICHARD MUTSCHELE. Fr. 635,268, July 3, 1926.

Combined carbide can and water receptacle suitable for refilling miners lamps. ANDREW KOZAK. U. S. 1,684,996, Sept. 18.

Ultra-violet ray lamp construction. J. ROBINSON. Brit. 284,746, Oct. 28, 1926. Screens are provided to obtain a spectrum from the lamp similar to that of solar light as received at the surface of the earth.

X-ray tube. MONTFORD MORRISON. U. S. 1,685,928, Oct. 2. Structural features.

Electron tubes (x-ray tubes, etc.). EUGÈNE ROUGE. Fr. 635,925, June 13, 1927. A layer contg., in part at least, a dioxide of an alk. earth metal, *e. g.*, BaO_2 is formed on the cathodes of electron tubes. Cf. *C. A.* **22**, 1708.

Base for electron tubes. THOMAS SCHWARZOTT. Austrian 108,865, Oct. 15, 1927. Constructional details.

Röntgen tube. SIEMENS-REINIGER-VEIFA (Ges. für medizinische Technik m. b. H.). Fr. 635,694, June 9, 1927.

Arrangement for adjusting Röntgen tubes. SIEMENS REINIGER-VEIFA (Ges. für medizinische Technik m. b. H.). Fr. 635,758, June 10, 1927.

Evacuating Röntgen-ray tubes and other high vacuum devices. H. C. RENTSCHLER (to Westinghouse Lamp Co.). Brit. 284,623, Feb. 1, 1927. A "getter" of Al is used which absorbs H and other gases and may be originally secured to the anode by welding or by inserting under a struck-out strap. Various other features are described.

Vacuum tubes. E. Y. ROBINSON and METROPOLITAN-VICKERS ELECTRICAL CO., LTD. Brit. 285,536, Nov. 9, 1926. Various structural features are specified. Multiple filaments mounted on a frame may be coated (as described in Brit. 285,538) with oxide or with a metal or compd. subsequently converted into oxide or may be otherwise treated to reduce the work function, *e. g.*, thoriated W filaments may be treated with a reducing agent such as C. Brit. 285,537 also specifies structural features. Zigzag filaments or the like may be mounted on hooks suitably formed of Mo or W and which may be repeatedly dipped in an aq. suspension of porcelain and kaolin and dried and finally treated with a blowpipe flame to effect fusion of the coating. Brit. 285,538 specifies fine filaments which may be provided with a sheath of different metal (which may be applied by the Wollaston process) which may be subsequently removed, *e. g.*, a Ag sheath on a Pt-Ir filament may be dissolved with dil. HNO_3 or removed by heating *in vacuo*, and after removal of this coating an oxide coating may be applied which may be converted into carbonate or carbonate coatings may be formed from nitrates such as those of Ba or Sr by reaction with CO_2.

Electric vacuum tubes. NAAMLOOZE VENNOOTSCHAP PHILIPS' GLOEILAMPENFABRIEKEN. Brit. 285,434, Feb. 16, 1927. Cathodes to be operated at incandescence are formed with a core such as W wound with Ni wire coated with alk. earth oxides and heated in O or other oxidizing atm. (suitably at 1000° with a coating of BaO). Cf. *C. A.* **22**, 1501.

Electrical contacts for vacuum tubes. STERLING G. SEARS (to Naylor Radio Corp.). U. S. 1,684,973, Sept. 18. Vacuum tubes with pins of oxidizing metal are provided with caps of spring metal having contact surfaces of Au or other non-oxidizing metal.

Furnace. STEPHEN MOGYORÓS and STEPHEN VISI. Fr. 634,703. May 19, 1927. A furnace has 2 combustion chambers and a smoke conduit, one extremity of which can be put in communication with one or other of 2 ash-pits of the app., while the other extremity can communicate with one or other of the combustion chambers, so that the smoke, etc., from one of the chambers, freshly stoked, is directed to the ash-pit and so to the hearth of the other chamber.

Furnaces. CHAUFFAGE ET RÉCUPÉRATION THERMIQUE. Fr. 635,155, Sept. 29, 1926. High temps. are reached in furnaces by feeding the burners with previously mixed gas and air, the air at least being heated before mixt.

Furnace using powdered coal. CARL BRACKELSBERG. Fr. 635,385, June 1, 1927. The powdered coal is introduced directly into the furnace, *e. g.*, a rotating furnace, without the usual antichamber.

Combustion chamber of coal dust furnace. KARL HUFSCHMIDT. Fr. 636,039, June 16, 1927. The space between the arched walls of the chamber and the exterior envelope is filled with granular material, which serves as a flexible support.

Shaft furnace or gas producer construction. STETTINER CHAMOTTEFABRIK A.-G. VORM DIDIER and E. TERRIS. Brit. 284,639, Feb. 2, 1927.

Gas burner suitable for furnaces. HAROLD D. SCHRADER. U. S. 1,686,711, Oct. 9.

Burner construction for regenerative furnaces. MICHAEL J. LACKNER. U. S. 1,685,543, Sept. 25.

Furnace "efficiency." JACOB M. SPITZGLASS (to Republic Flow Meters Co.). U. S. 1,686,186, Oct. 2. A temp. indicator moves away from a CO_2 indicator as the temp. of stack gases increases and toward it as the temp. decreases and the CO_2 indicator moves toward the temp. indicator as the % of CO_2 in the stack gases increases and moves away as it decreases.

Thermocouple and associated electric system for controlling the temperature of furnaces, etc. HARLAN S. GANO (to Westinghouse Elec. & Mfg. Co.). U. S. 1,685,995, Oct. 2.

Apparatus for the combustion of heavy liquid fuels. ANDRÉ MINNE. Fr. 32,662, May 20, 1926. Addn. to 623,437.

Apparatus for low-temperature distillation of coal, wood, oil shale, etc. HENRY G. LYKKEN. U. S. 1,685,496, Sept. 25. The material under treatment is heated in an annular pan having inlet and outlet ports and scrapers for moving the material along the pan from the inlet toward the outlet port.

Heat-exchange device. C. H. POTTS. Brit. 285,524, Oct. 8, 1926.

Heat-exchange apparatus with tubes for holding one fluid while another passes around the tubes. SOC. ANON. DES ETABLISSEMENTS DELAUNAY-BELLEVILLE. Brit. 284,338, Jan. 29, 1927.

Tunnel kiln construction. WOODALL DUCKHAM (1920), LTD., AND A. M. DUCKHAM. Brit. 285,323, Aug. 12, 1927.

Rotary kiln construction. VICKERS, LTD., AND L. D. PARKER. Brit. 284,494, March 23, 1927.

Rotary kiln for treating wet slurry, etc. J. S. FASTING. Brit. 284,276, Jan. 27, 1927. Structural features.

Kilns. JOHANN LAURENZ FURIAKOVICS and KARL HUHN. Austrian 108,079, Oct. 15, 1927. Constructional improvements are described in the stirring devices of pyrites burners, etc.

Gas burner. WILLIAM L. SHARP (to Ohio Foundry & Mfg. Co.). U. S. 1,684,457, Sept. 18.

Gas burner. PHILIP J. SONNER. U. S. 1,684,647, Sept. 18.

Gas burner with automatic safety valve. HENRIK BACH. U. S. 1,687,358, Oct. 9.

Gas generator with a grate and a rotating ash-removing bar over the grate. C. W. ANDREWS and W. B. CHAPMAN. Brit. 284,805, Nov. 22, 1926. Various structural features are specified.

Apparatus for analysis of gas. MARCEL J. E. CHOPIN. Fr. 32,607, Dec. 7, 1926. Addn. to 597,636. A hydraulic arrangement allows the formation over a relatively long time of a sample of gas and its rapid delivery to the analyzer. The contents of a vessel fed by a detd. flow of water are emptied into the body of a pump and the pump gradually evacuates. The pump is connected on the one hand with the gas to be analyzed and on the other to the analyzer by suitable valves.

Indicator for the automatic analysis of gas. MONO G. M. B. H. Fr. 32,567, Nov. 22, 1926. Addn. to 582,062. Improvements are described in an app. for automatically indicating at a distance the analysis of a gas on a system of absorption.

Electrically operated valve suitable for supplying gas to burners. HENRY L. STEPHENSON. U. S. 1,684,603, Sept. 18.

Apparatus for observing the color, turbidity or rotation of the plane of polarization of liquids or gases. F. HERZFELD-HOFFMANN. Brit. 284,607, Jan. 31, 1927.

Apparatus for washing gas or air. SAMUEL N. CHEW and PNEUMATIC CONVEYANCE AND EXTRACTION, LIMITED. Fr. 635,763, June 10, 1927.

Valve for gas and hot blast. WESTFALISCHE METALLWERKE & CIE. Fr. 635,997,

June 15, 1927. The seating rings form part of the body of the valve and the whole is traversed by a system of canals for the circulation of a refrigerating medium.

Valve and pipe system and diaphragm governor for proportionately mixing air and fuel gas or other fluids. Garnet W. McKee. U. S. 1,684,500, Sept. 18.

Apparatus (with a coir fiber filter) for filtering and moistening air. A. C. Handley. Brit. 285,561, Nov. 17, 1926.

Apparatus for drying solid particles carried by gases and for precipitating salts from solution by cooling. P. Schmidt. Brit. 285,046, Feb. 9, 1928. Gases carrying particles to be dried are conducted between a fixed heated plate and a closely spaced adjacent rotary plate. For crystn., an app. may be used in which the soln. flows upwardly through a duct into the space between a water-cooled rotary chamber and a fixed plate; the crystals collect beneath the fixed plate and the solvent flows away above the rotary chamber (which is of flat plate form).

Device for separating dust from air, etc., by centrifugal action. A. Stievenart. Brit. 284,980, Feb. 4, 1927. A water spray may be used in the device specified.

Device for removing suspended solid particles from air or other gases by centrifugal action. F. S. Talty and J. W. Gover. Brit. 284,221, Jan. 24, 1927.

Baffle device for separating solid particles from smoke and gases. A. Parker. Brit. 284,398, Oct. 27, 1926.

Centrifugal apparatus for separating carbonized particles from distillation gases. Trocknungs-Verschwelungs- und Vergasungs Ges. Brit. 285,387, Feb. 14, 1927.

Apparatus for treating furnace gases to remove dust and carbon dioxide. C. V. A. Eley. Brit. 285,544, Nov. 15, 1926. The gases are filtered and treated with alkalies such as lime or soda.

Apparatus for liquefaction and rectification of air or other gases. W. L. de Baufre (to S. G. Allen). Brit. 285,468, Feb. 18, 1927.

Apparatus for the liquefaction and separation of gaseous mixtures, particularly air, into their constituents. Christian W. P. Heylandt. Fr. 635,855, May 21, 1927. The entering air is divided into two parts; one part passes into an expansion vessel and from this, after passage through a heat exchanger, to a high-pressure column of a sepn. app. The other part, expanded by its passage through a heat exchanger and evaporator, is led through a throttling valve into the high-pressure column.

Apparatus for absorbing gases by liquids. V. N. Golovanov. Russ. 4046, Nov. 15, 1927.

Apparatus and system for maintaining constant heating value per unit volume in gases such as formed by mixing two different gases supplied through a conduit. Ulric O Hutton and Edwin X. Schmidt (to Cutler-Hammer Mfg. Co.). U. S. 1,686,751, Oct. 9.

Metal vessel arranged for heating or cooling by chemical reactions. K. Gyorgy. Brit. 285,511, Feb. 19, 1927. Various structural details are specified of a device which may be heated with lime and water or cooled by NH_4NO_3 and water.

Cylinder and plunger apparatus for emulsifying various liquids. Guy C. Hurrell. U. S. 1,685,424, Sept. 25.

Colloid mill and emulsifying apparatus. J. Bourdais. Brit. 285,258, March 1, 1927.

Centrifugal apparatus for mixing or emulsifying liquids. A. C. E. Anderson-Orris. Brit. 284,910, May 17, 1927.

Apparatus for emulsifying milk powder, water and butter or other materials. G. C. Hurrell. Brit. 285,159, Nov. 13, 1926. A plunger is positioned in a cylinder with a slight clearance space through which the materials under treatment are forced by the action of the plunger.

"Centrifugal liquid crucible." Juvenal Maximoff and Maria S. de Costa. U. S. 1,684,800, Sept. 18. A rotatable and heated app. is described adapted to form Cu, Mn, Cr or other suitable molten metal into crucible shape so that it may serve for holding quartz during melting or for other high-temp. operations.

Apparatus for drying, evaporating, disinfecting and heating under vacuum. F. F. Gartung. Russ. 4183, Dec. 31, 1927.

Apparatus for drying fruits, vegetables or other materials with preheated air. Frederick E. Whorff. U. S. 1,686,500, Oct. 2.

Apparatus for drying paper or other materials in long lengths. A. Lambrette. Brit. 285,378, Feb. 14, 1927.

Drying cylinder for paper, textiles, etc. Bernhard Wicky and Herbert Schmolka. Austrian 109,048, Nov. 15, 1927. Constructional details.

Vertical column apparatus for drying coal, grain or other bulk materials. OLIVER W. RANDOLPH. U. S. 1,685,338, Sept. 25.

Drying tunnel with devices for heating and circulating air. H. WINKLER. Brit. 284,747, Oct. 28, 1926.

Electrical method for determining and controlling the humidity of substances such as paper, cellulose and air. JAMES D'ARGAVILLE CLARK. Fr. 635,296, May 17, 1927.

Extrusion press for expressing liquid from peat or other materials. H. SKÖLDBERG. Brit. 284,318, Jan. 29, 1927. Structural features.

Apparatus for clarifying used "dry cleaning" liquids by filtration, alkali treatment, etc. FRANK E. BOWERS. U. S. 1,687,235, Oct. 9.

Thickening for separating solids in muds formed in sugar production or other hot solid-liquid suspensions. HARRISON S. COE. U. S. 1,686,203, Oct. 2.

Boiling-pans. I. G. FARBENIND. A.-G. Brit. 284,281, Jan. 27, 1927. Pans for heating or cooling by means of ordinary or Perkins tubes have an enamel coating on a cast iron lining or outer coating.

Spray attachment for retorts for heating bottles, etc. ROBERT A. SINDALL (to Mavis Bottling Co. of America). U. S. 1,685,884, Oct. 2. Structural features.

Horizontal pipe system for separation of lighter and heavier portions or ore mixtures, etc., by flowing liquid. A. C. HOUDIJK. Brit. 284,826, Dec. 16, 1926. Upper and lower branch discharge pipes lead off the sepd. constituents.

Apparatus for continuous mixing and delivery of "lard compound" or other semisolid materials. RALSTON B. BROWN. U. S. 1,686,953, Oct. 9.

Safety vapor outlet for containers holding petroleum distillates, or other inflammable materials. RICHARD J. MONNETT (to Monnett Co.). U. S. 1,686,918, Oct. 9. A thermo-expansive device in a vent pipe serves to close a pressure relief valve in the pipe when heated.

Centrifugal, grinding and comminuting apparatus for mixing, emulsifying, homogenizing or comminuting various materials. H. HILDEBRANDT. Brit. 284,354, Jan 28, 1927.

Apparatus for cooling hollow pistons, etc. FRANZ PUENING. U. S. 1,687,142, Oct. 9. A device such as a piston propelling hot gases is supplied simultaneously on its interior and exterior surfaces with a relatively cool fluid such as air or other suitable gas.

Rolling-mill rolls (with helical passages for cooling water). C. ROTZEL. Brit. 285,358, Feb. 12, 1927.

Electric discharge apparatus. COMPAGNIE FRANÇAISE POUR L'EXPLOITATION DES PROCÉDÉS THOMSON-HOUSTON. Fr. 635,999, June 15, 1927. Constructional features.

Electric discharge device for producing slight ultra-violet radiation. F. MEYER, H. J. SPANNER and E. GERMER (to Naamlooze Vennootschap Internationaal Octrooibureau). Brit. 285,068, Feb. 11, 1927. Devices for producing slight ultra-violet radiation, non-injurious to the eyes or other parts of the body, and applicable to sterilizing air of rooms or for other purposes, comprise a vessel which may be formed of quartz, uviol glass or the like (or having a window of such material), in which a glow discharge is produced between cold electrodes in an atm. of one or more rare or base gases and Hg or other metallic vapor. Various details are specified.

Annealing pot with reinforcing metal inside its corners. ROBERT S. STEWART (to American Brake Shoe & Foundry Co.). U. S. 1,685,966, Oct. 2.

Elements for filling heat regenerators. JOHN R. BUFFINGTON (to Decarie Incinerator Corp). U. S. 1,687,236, Oct. 9. Structural features.

Apparatus for feeding measured quantities of sodium aluminate or other dry materials. WILSON EVANS (to National Aluminate Corp.). U. S. 1,686,077, Oct. 2.

Apparatus for the determination of the size of grain in powders. M. S. KOSMAN and P. I. LUKIRSKII. Russ. 4110, Nov. 30, 1927.

Apparatus for dissolving sugar and the like with automatic regulation of the density. EDMOND LE BOS. Fr. 635,285, May 2, 1927.

Acid-resisting constructions. JOHANN K. WIRTH. Fr. 635,399, June 1, 1927. Mixts. of artificial phenol-aldehyde resins which can be hardened in the cold or at a moderate temp. by acid or acid salt are used for coating metals, or for cementing plates in acid-resisting constructions, or the constructions are made from the resins reinforced with Fe or the like.

Apparatus for grading heavy substances such as coal or ores. MIGUEL B. SUAREZ Fr. 635,240, May 30, 1927.

Crushing machine. ALLIS-CHALMERS MANUFACTURING COMPANY. Fr. 635,909,

June 13, 1927. A crushing machine for rocks, ores, coal, etc., is of the gyratory type, having two relatively rotating crushers which form between them an annular chamber narrowing toward the base. The axes or rotation of the two crushers intersect, so that they move eccentrically to one another.

Grinding machine for cement, lime, coal, phosphates, etc. SOCIÉTÉ DES TRANSMISSIONS MODERNES ET DES ENGINS BROYEURS. Fr. 635,243, May 30, 1927.

Control valve. SCHIFF AND STERN. Austrian 108,984, Oct. 15, 1927. A control valve operated by variations in fluid pressure is described, particularly for use in water-condensing plants.

Device for separating oil drops from steam. JOSEF MUCHKA. Austrian 108,935, Oct. 15, 1927. Constructional details.

Device for determining the resistance of bodies to friction. MOSES SPINDEL. Austrian 109,121, Nov. 15, 1927. Constructional and manipulative details.

Thermostat for controlling electric circuits. WELLINGTON J. SMITH. U. S. 1,687,230, Oct. 9.

Thermostatic control device for electric heaters. LEWIS H. LAMONT. U. S. 1,684,544, Sept. 18.

Thermostatic device for controlling electric circuits. HERBERT D. MONTGOMERY. U. S. 1,685,136, Sept. 25.

Thermostatic control device for electric circuits. IRA E. MCCABE. U. S. 1,686,-286, Oct. 2.

Thermostatic control for electric switches. HERBERT J. SAUVAGE (to Electric Thermostatic Control Co.). U. S. 1,686,766, Oct. 9.

Thermostatic regulator for electric circuits. AUGUST J. MOTTLAU (to Westinghouse Elec. & Mfg. Co). U. S. 1,686,634, Oct. 9.

Mercury relay for thermostats. A. I. DANILEVSKII. Russ. 4062, Nov. 30, 1927.

2—GENERAL AND PHYSICAL CHEMISTRY

GEORGE L. CLARK AND J. H. REEDY

Léon Guignard, 1852-1928. VERDA. *Schweiz. Apoth. Ztg.* **66**, 175–7(1928).—An obituary. S. WALDBOTT

Svante Arrhenius. OSSIAN ASCHAN. *Finska Kemistsamfundets Medd.* **36**, 66–75 (1927).—Biography with portrait. E. J. C.

Jean Werth (1855-1928). LÉON GUILLET. *Rev. métal.* **25**, 479–80(1928).—An obituary with portrait. A. PAPINEAU-COUTURE

Recent advances in science: Physics. L. F. BATES. Univ. London. *Science Progress* **23**, 203–11(1928).—A review of recent work on single crystals of Bi and Ni, the magnetic state of the Co" ion, the origin of magnetism, and contact differences of potential. JOSEPH S. HEPBURN

The saturated vapor pressure of solutions. M. LEVAL'T-EZERSKIĬ. *J. Russ. Phys.-Chem. Soc.* **59**, 89–111(1927).—A generalized form of Raoult's equation has been proposed (*C. A.* **21**, 3519) which holds for the osmotic pressure of any soln.: $(p-p_1)/p = ni/(N+in)$ where N is no. of mols. of water, n that of the solute and $i = \Delta t$ observed/Δt calcd. Setting Δt calcd. $= E$, we have: $(p-p_1)/p = \Delta t$ observed/(Δt observed $+ EN$), where Δt refers to f. p. depression or b. p. elevation. Assuming p to be the vapor pressure of water and p_1 that of the soln. at a given temp., the temp. rise necessary to make the vapor pressure of soln. reach the value of p, $\Delta t = ENp/(p_1 - 1)$. Since the ratio p/p_1 does not change with the temp. over a wide concn. range (*C. A.* **21**, 3519), Δt remains constant between 0 and 100°. Also, two solns. of equal vapor pressure at a given temp. will remain so at other temps. The Magnus formula for the vapor pressure of pure water ($p = p_0 \cdot 10^{\frac{at}{C+t}}$, where p_0 is pressure at 0°, t temp., $a = 7.4475$ and $C = 234.69$) applies to concd. solns. of KNO_3, K_2SO_4, $NaNO_3$, Na_2SO_4 and NaCl (exptl. data by Tammann and by Dieterici). The calcd. values were cor. for the difference between calcd. and observed values of the vapor pressure of water at corresponding temps. A single reliable observation is thus sufficient to compute the vapor pressure of a soln. (concns. up to 3 molar) at any temp. For more concd. solns. two observations at different temps. are necessary in order to correct for the non-conformance to Babo's law. The constants a and C of Magnus have the same value in all the cases considered. Or, the state of aggregation of water in solns. is the same as that of pure water. BASIL C. SOYENKOFF

A 5000-year-old aqueous solution. MAX MEYERHOF. *Arch. Cesch. Math., Naturwiss., Tech.* **10,** 336–7; *Chem. Zentr.* **1927,** II, 2209.—The communication describes a preservative fluid which was found in an Egyptian tomb, and consisted of a 3% aq. NaCl soln. contg. Na_2SO_4 as an impurity. It was used in ancient times as a *preservative agent for the internal organs of the dead.* C. C. DAVIS

The discovery of the gas laws. I. Boyle's law. W. S. JAMES. *Science Progress* **23,** 263–72(1928).—The law of Boyle and Mariotte was announced by Boyle in 1661, and by Mariotte in 1676. Boyle is therefore entitled to priority. J. S. H.

Problems of the Brownian molecular movement. FRIDA STADIE. *Ann. Physik* **86,** 751–97(1928).—This is a purely mathematical treatment of a no. of problems connected with the Brownian movement. W. W. STIFLER

Scientific and engineering symbols and abbreviations. J. FRANKLIN MEYER *et al.* *Mech. Eng.* **50,** 797–808(1928).—A list of symbols for hydraulics, aeronautics and electrical quantities, recommended by the Committee for Standardization of Scientific and Engineering Symbols and Abbreviations. T. S. CARSWELL

High-pressure-gas research at the University of Illinois. NORMAN W. KRASE. Univ. of Illinois. *Chem. Met. Eng.* **35,** 463–5(1928). E. H.

Hydrogen overvoltage and reduction of oxalic acid at mercury cathodes. P HERASYMENKO. *Z. Elektrochem.* **34,** 129–36(1928).—Researches (Heyrovsky, *C. A.* **19,** 2905; Herasymenko, *C. A.* **19,** 2905) have shown that the cathodic decompn. potential of H_2, at Hg, is greatly dependent on the H-ion concn., Heyrovsky giving an explanation in which H_2 is supposed to be produced in three steps. The relation between this potential and the H-ion concn. is detd. as: $\pi = (2RT/F) \ln[H^+] + k$, giving values in good agreement with expt. The relation between i (the current intensity) and the cathode potentials, at the temps. of the expts., is obtained as: $i = k \cdot [H^+]^{4/3} \cdot e^{-(2\pi F)/(3RT)}$, agreeing with the exptl. current-voltage curves. Contrary to Moeller (*C. A.* **2,** 2489), no max. in overvoltage is obtained between —4° and 10°, at Hg cathodes. The temp. coeff. of the potential of H_2 evolution at Hg cathodes is detd. as 0.003 v. per 1°, due to increased catalytic activity of H ions. Unlike other org. acids, oxalic acid influences the H overvoltage. The behavior of oxalic acid is explained by assuming that it forms the solvation compd., $H^+ (C_2O_4H_2)_n$, by reacting with H^+, the H^-, formed on the surface of the cathode, reacting with oxalic acid to give glyoxylic acid and H_2O. The relation giving the cathode potential of oxalic acid reduction is detd. as: $\pi = (RT/F) \lg [H^+]^2[O^-]^{2.4} + \pi_0$, where π_0 is the "normal" reduction potential of solns. molal in oxalic acid and normal in H ions. J. BALOZIAN

The practical value of physical apparatus and methods in the progress of the natural sciences. RICHARD KEMPF. *Chem.-Ztg.* **52,** 649(1928).—A review. R. D. BUMBACHER

A space model of the periodic system of elements. A. SLINGERVOET RAMONDT Kon. Inst. v. d. Marine, Helder. *Chem. Weekblad* **25,** 496–8(1928).—A description and photograph are given of a space model according to Monroe and Turner (*C. A* **20,** 3251) with loops of 2, 6, 10 and 14 elements. B. J. C. VAN DER HOEVEN

Atomic weight. A. v. FISCHER-TREUENFELD. *Ann. Physik* **85,** 1113–6(1928).—The at. wt. of an element is given approx. by the formula: $\sqrt[3]{W} = \dfrac{3\sqrt[3]{2Z} + 5\sqrt{(Z-1)/3} + 1}{8}$, where W is the at. wt. and Z is the at. no. R. L. H.

Combining ratio of copper and sulfur. Experiment for high schools. CHARLES H. STONE. Eng. High School, Boston. *J. Chem. Education* **5,** 1129–30(1928).—A high school quant. expt. on the formation of Cu_2S from Cu and S is described. Consistent results are obtained by students. L. D. R.

Eutectic freezing point lowering in binary mixtures. V. The determination of molecular weight from the position of the eutectic. E. KORDES. Kaiser-Wilh. Inst für Silicatforschung. *Z. anorg. allgem. Chem.* **173,** 1–13(1928); cf. *C. A.* **22,** 2100 – When binary systems contain satd. mixed crystals in the solid phases or incomplete miscibility in the liquid phase, departures from the general equation for eutectic f. p. lowering result which are qualitatively the same as for the f. p. lowering in dil. soln., that is, the f. p. is higher than the equation indicates. Quant. relations between the magnitude of the departures from the eutectic f. p. lowering for "normal" binary systems and the compn. of the mixed crystals or the gap in miscibility have not been discovered. The general eutectic equation provides a method for detg. mol. wts. which has the advantages over methods based upon the laws of Raoult and of van't Hoff that it is not limited to dil. solns. and is just as applicable to electrolytes as to nonelectrolytes. F. L. BROWNE

Coördination and atomic structure. PRIYADARANJAN RĀY. *Z. anorg. allgem. Chem.* **174**, 189–92(1928).—Complex compds. are divided into 2 classes, the strong or complete, and the weak or incomplete complexes. To the first belong Co^{III}; Pt^{II}; Pt^{IV}; Cr^{III}; Rh^{III}; Ir^{III}; Ir^{IV}; etc. These are so classed because of their extraordinary complexity and characteristic chem. properties. The weak complexes are transition forms between the true complexes and double salts or mol. compds. The various coördinating valences or bonds are arranged into pairs of partial orbits which show a linkage of the various electron orbits. The following factors may be considered as controlling the formation of complex compds.: (1) the charge of the central ion, which is the source of attraction; (2) the tendency of the central ion to assume the configuration of the next highest rare gas; (3) the nature of the electron arrangement in the central atom; (4) the coördinative groups must be constituted in such a way that 2 electrons may be transferred to the central atom for each coördinative binding. The influence of the vol. of the central ion is included in (1), the smaller the vol. the greater the attraction. An assumption which may be useful in considering the nature of the electron distribution in the central ion is that every 2 electrons tend to form a strong bond. A single electron in one of the outer orbits gives a seemingly unstable arrangement. The stability of each sub-group increases with the no. of electrons contained therein. Tables of the electron arrangement of various complexes are given.

L. L. QUILL

The shape of the carbon dioxide molecule. CLEMENS SCHAEFER. Univ. Breslau. *Physik. Z.* **28**, 667(1928).—Polemical against Stark and Blüh (*C. A.* **22**, 1510). S. distrusts many measurements of the electric moment of CO_2, and refuses to admit the linear shape of the mol.

A. L. HENNE

Role of valence and electrons in the teaching of general chemistry. W. M. BLANCHARD. DePauw Univ. *Proc. Indiana Acad. Sci.* **37**, 245–53(1927).—Combination, decompn. and displacement reactions may now be grouped together and explained on the grounds of valence changes if one assumes (1) an element in the free state has zero valence; (2) H in combination has a positive valence of 1, *i. e.*, each atom has lost one electron; (3) O in combination has a neg. valence of 2, *i. e.*, it has gained 2 electrons, but in peroxides one must assume it has a valency of —1. Excepting double decompn. reactions, chem. action in general may be interpreted as an oxidation-reduction process, *i. e.*, electronic transfer. Some elements tend to lose electrons, *e. g.*, Be, Cu, Au, etc.; some tend to gain them, *e. g.*, Cl, S, N, etc.; and some elements have a more equalized tendency. The reaction between an acid and a metal may be written $Zn \longrightarrow Zn^{2+} + 2e$ or $2H^+ + 2e \longrightarrow H_2$. To obtain SO_2 from H_2SO_4, S^{+6} must be reduced to S^{+4}; hence some element is required with not too great a facility for electronic acquisition or free S or even H_2S may be obtained. Some elements may play a double role and the atoms may acquire electrons from other similar atoms of the same element and self oxidation may occur as in HClO. B. illustrates this by the electronic events connected with Cl^{+7} and H_2O and also bleaching powder. He gives other examples in PH_3 and K hypophosphite, and the prepn. of iodine from either iodide or iodate. He considers the cases of $K_2Cr_2O_7$ with Fe^{+2}, Sn^{+2} and H_2SO_3. In $K_2Cr_2O_7$ + $FeSO_3$, would ferric sulfite or ferrous sulfate be first formed or would oxidation of Fe and S occur simultaneously? The interaction of Na_2O_2 and a chromic salt is considered with its implication of a structural formula for the peroxide and also the reaction between $KMnO_4$ and H_2O_2 in acid soln. Is there any inconsistency in regarding H_2O_2 as an oxidizing agent with a chromic salt and a reducing agent with $KMnO_4$? None, any more than there is in regarding Zn as electronegative to Mg and electropositive to Cu. No generally satisfactory explanation has been given of uncombined H_2 and Cl_2 being very stable, yet when mixed combining with great vigor. The possibility of 2 distinct kinds of atoms of chlorine, oxygen, nitrogen, etc., is indicated.

S. L. B. ETHERTON

An aspect of the problem of valence in inorganic chemistry. PAUL DUTOIT. *Bull. soc. chim.* **43**, 785–99(1928).—The present status of the application of valence to inorg. chemistry is considered. Suggestions are made for the assigning of polar valence numbers to elements in hitherto avoided compds. Cases where the polar valence number is zero and the possibility of isomerism through a difference in valence are discussed.

LUCY K. PICKETT

Modes in which valency is exercised. I. The tetrahedral carbon atom. Paraffins and polymethylenes. HENRY E. ARMSTRONG AND WM. BARLOW. *Chemistry and Industry* **47**, 892–7(1928).—A regular rhombic dodecahedron is chosen to represent unit valency; one of these represents a univalent atom; two in face contact a bivalent atom; three joined triangularly, a tervalent atom; four tetrahedrally, a quadrivalent

atom, as C, thus carrying further van't Hoff's original idea of the tetrahedral C. From these at. models, models of paraffins and polymethylenes have been built, showing the ways in which the atoms may be joined together. **II. The structure of graphite and black carbon.** H. E. ARMSTRONG. *Ibid* 897-8.—Since both black C and diamond yield graphite on heating, and since the ethenoid linkage has to do with color, A. suggests that graphite itself may be the missing equilibrated complex in the carbon scheme, and be composed of alternate diamond or normal paraffinic and ethenoid (black) carbon layers. G. R. YOHE

Specific heat and internal pressure of liquids. K. M. STAKHORSKIĬ. *J. Russ. Phys.-Chem. Soc.* **60,** 163-70(1928).—$M(C_p - C_v)$ varied little from the av. of 10.5 for 10 org. liquids. Association factors x calcd. for AcOH, MeOH, EtOH, BuOH and AmOH from $x = 10/[M(C_p - C_v)]$ (1) were in agreement with values otherwise obtained. Combining $M(C_p - C_v) = 0.0242\ T\alpha^2 Mv/\beta$ with $B = T\alpha/\beta$ (*Ann. chim. phys.* [4], **2,** 185(1864); **6,** 274(1865)), S deduces $B = M(C_p - C_v)/(0.0242\ Mv\alpha)$ (2) and $\beta = M\ (C_p - C_v)/(0.0242\ \Delta Mv)$. From (1) follows $B = 413.2/(xMv\alpha)$. (3). Values of internal pressure B obtained from (2) for normal liquids agree with those calcd. from (4) $B = 236\ \gamma t/_{k_n}$ (*C. A.* **21,** 2092). The agreement is also close for MeOH, and EtOH (about 3000 atm.) but not for H_2O at lower temps. B of associated liquids is of the same order of magnitude as of normal liquids. B. C. S.

The theory of the periodic system and the evolution of wave mechanics. A. SOMMERFELD. *Z. angew. Chem.* **41,** 1-6(1928).—An address presenting in popular form modern at. theories with especial reference to the contributions of the new wave mechanics of Schrödinger. G. L. CLARK

Germanium. L. M. DENNIS. *Z. anorg. allgem. Chem.* **174,** 97-141(1928).—A review article on the work done at Cornell Univ. on Ge between the years 1921 and 1927. The studies show the similarity in the properties of Ge and its compds. to those of the other elements in Group IV. Metallic Ge is similar in many respects to Si, *i. e.,* brittleness, high m. p., resistance to acid and alk. solns. Like Sn, it is distinctly metallic, forming well-defined crystals. H_2O_2 is the best solvent now known for Ge. In its compds., Ge shows variable valence, a property which increases in each group with at. no. increase. With the exception of CO and SiS, bivalent compds. of C and Si are either not known or not recognized. C and Si readily form compds. of higher valence; Ge shows the property of bivalence as well. GeO is easily prepd., is fairly stable in air, is definitely basic, reacts with halogen acids to form the dihalides, and reduces H_2O_2 and $KMnO_4$. With increasing at. no. in any group, the compds. of lower valence of the members show a greater stability. SnO and PbO are more stable than GeO; Sn^{II} exhibits reducing properties; Pb^{II} does not. Ge dihalides are not difficult to prep. although they are less stable than the corresponding Sn and Pb salts. Dihalides of C and Si are not known. The Ge dihalides are easily converted to the tetrahalides by the free halogen. $SnCl_2$ behaves similarly but $PbCl_2$ does not. Ge dihalides easily form compds. of the type $GeHX_3$ with the gaseous H halides, thus showing a similarity to C and Si but not to Sn and Pb, which do not form compds. of this type, except SnI_2HI. Ge, like Sn and Pb, forms a stable sulfide, GeS. The quadrivalent Ge compds. thus far isolated are similar to the corresponding Si compds., especially when the non-polar compds. with H and the halogens are referred to. Hydrated GeO_2 is formed by the decomposition of $GeCl_4$ with H_2O, the product formed being somewhat sol. as is the case with SiO_2. GeO_2 is reduced by H_2 at high temp. differing in this respect from Si. GeO_2 melts to a glassy form at very high temp. like SiO_2. It may be substituted for SiO_2 in glasses. GeO_2 differs from Si and Sn, in that it may be converted quickly and completely into $GeCl_4$ by heating with concd. HCl. GeS_2 is pptd. from solns. by H_2S, but since it is sol. in H_2O the pptn. is complete only in high acid concn. The tetrahalides of the elements from C to Pb in Group IV show a decreasing stability with increasing at. no. $PbCl_4$ decomps. readily. Ge tetrahalides are easily prepd. by the action of the halogens on the metal. GeF_4 and $GeCl_4$ may be prepd. by other methods as well. The stability of the tetrahalides decreases with increasing at. no. of the halogen. $GeCl_4$ is reduced with difficulty, while $SnCl_4$ is easily reduced. The similarity of the non-polar compds. of Ge, C and Si is shown in the hydrides of the type Ge_nH_{2n+2}; Sn and Pb show this property to a very slight extent. GeH_4, Ge_2H_6, and Ge_3H_8, have been prepd., and higher homologs are probably formed. Only a few org. compds. of Ge have been prepd.; yet from their methods of prepn. and properties, they show the close relationship of Ge to C and Si. A bibliography is included. L. L. QUILL

The hygroscopic and catalytic properties of electrolytic copper containing gelatin. C. MARIE AND P. JACQUET. *Compt. rend.* **187,** 41-3(1928).—Electrolytic Cu, deposited

in the presence of gelatin, contains a surcharge of gelatin, $CuSO_4$ and H_2O. The deposit is highly hygroscopic and when heated to 100° catalyzes the combination of H_2 and O_2. These properties show the high porosity of the deposits. E. G. V. B.

Some physical properties of platinum. A. T. Grigor'ev. *Ann. inst. platine (Leningrad)* **1928**, No. 6, 178-83.—Elec. cond. and hardness of a carefully purified sample of Pt have been measured. Elec. cond. measurements at 25° and 100° yielded: $\lambda_{25°}.10^{-4} = 9.190$; $\lambda_{100°}.10^{-4} = 7.248$; $\alpha_{25-100} = 0.00392$. The measurement of the hardness was carried out by the method of Brinnell (*Dingl. polytechn. J.* **320,** 280(1905)), yielding Brinnell nos. $H_{100} = 23.9$ and $H_{200} = 24.3$ for the pressures of 100 and 200 kg., resp. Furthermore, an analysis of the tech. Pt of the State factory in Swerdlowsk and detns. of its elec. cond. and hardness were carried out. The results are as follows: Impurities—Fe = 0.07%; Ir = 0.04%; Au = traces. $\lambda_{25}.10^{-4} = 8.736$; $\lambda_{100}.10^{-4} = 6.961$; $\alpha_{25-100} = 0.00372$; $H_{100} = 27.9$; $H_{200} = 28.8$. The elasticity limit of the tech. Pt was detd. to 3105.5 kg./cm². G. B. Kistiakowsky

The resistance hysteresis of tin, lead, indium and thallium at the temperature of liquid helium. W. J. de Haas and J. Voogd. Univ. Leiden. *Verslag Akad. Wetenschappen Amsterdam* **37,** 582-9(1928).—The hysteresis observed in the curves of resistance *vs.* magnetic field H at low temp. for Hg is confirmed on other metals. For tin (polycryst. wire, 3.60° abs., $R_{4.2°}$ = 0.00298 ohm.), the resistance changes with increasing H from 0 to 0.00128 at 21.40 gausses and with a few more small increases to the value 0.00268 at 50 gausses. On decreasing the field the first downward step of R is at 22.77 gausses to 0.00185 and the final one from 0.00162 to zero at 18.49 gausses. For indium (almost unicryst. wire, 3.01° abs., $R_{3.42°}$ = 0.001806 ohm) the upward rise begins at 60 gausses, the downward drop at 50.93 gausses. For lead (polycryst., 4.22° abs.) the up and downward curves continue to rise with H; they lie at 600 and 579 gausses, resp. The resistance of thallium (polycryst., 2.35° abs., $R_{4.2°}$ = 0.2452 ohm) starts upward from 0 at H = 25.08 gausses, continues to rise with H, reaches zero on decreasing H at 23.97 gausses. It is apparent that the hysteresis is a common effect for all supra-conductive metals; it is most marked for large crystallites in a homogeneous field. B. J. C. van der Hoeven

(Allotropic modifications of phosphorus.) Displacement of metals and their oxides by hydrogen under pressure at high temperatures. V. Ipat'ev. *Chimie & industrie* Special No., 411-4(April, 1928); cf. *C. A.* **21,** 1572; **22,** 2306.—According to I.'s most recent expts. white (colorless) P is formed: (1) by crystn. from C_6H_6 on cooling, but the cryst. aggregates are small; (2) the most perfect crystals are obtained by crystn. from C_6H_6 at about 200° and 60-70 atm.; they consist of long prisms which are transparent under the microscope and belong to the cubic system, as shown by the absence of double refraction under polarized light; (3) at 500° and over and 10 mm. or less, ruby-red P sublimes with transformation into white (colorless), cryst. P, m. 44.5°, d. 1.83, soly. in C_6H_6 0.65% at 15.6°. Red forms of P are obtained: (1) by heating ordinary P with Pb at 335° and 165 atm. in an atm. of N_2 or CO_2; under the microscope the crystals are ruby-red by transmitted light and violet with a metallic luster by reflected light; (2) by heating with powd. Fe or Mg the ruby-red crystals obtained are not violet by reflected light. All red forms have d. 2.11, ignite at 310-50° and are unaffected by polarized light, indicating that they crystallize in the cubic system. Analysis showed them to contain 99.5-99.9% P. Black forms are produced from ordinary yellow P and from red P by heating with H_2O at 200° or over, optimum conditions being 315° and 165 atm. They have d. 2.61, and contain over 99% P. Heating Pb with yellow P at 400° and 165 atm. gives fragile, cryst. P-Pb, d_{16}^{16} 3.68, contg. 65% Pb. 33% P and a slight insol. residue, corresponding approx. to PbP_3 but consisting of a solid soln. and not a chem. compd. Sn and yellow P at 285° and 90 atm. give a solid soln. of fragile crystals, d. 5.73, contg. 92.9% Sn and 7% P. Zn and yellow P at 250° and 100 atm. give blackish gray crystals of P-Zn contg. 91.46% Zn and 8.4% P, consisting of a solid soln. of ZnP_2 or Zn_3P_6 in excess Zn. Cu and yellow P at 350° and 105 atm. give homogeneous crystals contg. 85.75% Cu and 14.2% P, corresponding to Cu_3P. In all cases the metal and P were heated in CO_2 or N_2. The work reported on the reduction of Cu formate and $Cu(OAc)_2$ is abstracted in *C. A.* **20,** 2959; **22,** 13, and on $Pb(NO)_3$ in *C. A.* **22,** 2306. In order to confirm the theories proposed to explain the mechanism of the displacement of metals from salt solns. under the effect of H-ion concn., the effects of CO on $CuSO_4$ solns. at 160-220° and 20-100 atm. for 16 hrs. were studied. It was found that H_2O and CO reacted to give HCO_2H, which decompd. to give 2H and CO_2, and the results obtained confirmed the theories advanced on the effect of H-ion concn. on the reactions being studied. A. Papineau-Couture

The crystal structure of the alkaline earth metals. G. L. Clark, A. J. King and J. F. Hyde. Univ. of Illinois. *Proc. Nat. Acad. Sci.* **14**, 617–8(1928).—Very pure Ca, Sr and Ba are prepd. in a vacuum sublimation furnace, and samples, handled always in an atmosphere of argon, are subjected to x-ray analysis by the Hull method. Ca has a face-centered cubic structure in agreement with the results of Hull. Ba crystallizes on a body-centered cubic lattice with the const. 5.04 A. U. Sr has given patterns with very diffuse lines, at most, seven in number. The structure does not correspond to the face-centered lattice reported by Simon and Vohsen. It is evident that there are two or more modifications of Sr, and since it lies between Ca with face-centered and Ba with body-centered lattices, it is perhaps not strange that it should show anomalous results. The metal used was more than 99.9% pure. The work is being continued in an effort to discover the necessary conditions for production of sharp cryst. patterns. G. L. Clark

The crystal structure of solid mercury. M. Wolf. Univ. Groningen. *Nature* **122**, 314(1928).—The cryst. structure of solid Hg at —80° is detd. from powder photographs obtained with a special low-temp. spectrograph. A simple rhombohedral structure, agreeing with that of McKeehan and Cioffi (*C. A.* **17**, 2068) is found. R. J. H.

The value of the specific heats C_1 and C_2 of liquids and saturated vapors along the equilibrium line in the neighborhood of the critical temperature, also at T = 0 and a few remarked about the heat of vaporization at T = 0. J. J. van Laar. *Z. physik. Chem.* **134**, 311–28(1928).—A mathematical discussion. Near the crit. point, the sp. heat of the liquid C_1, and the sp. heat of the vapor C_2 tend, resp., towards $+\infty$ and $-\infty$. Near $T = 0$, the latent heat of vaporization tends towards a finite value (17.5 for He). G. Calingaert

The specific heats C_p and C_v of a few substances in the solid, liquid and hypercritical states between 80° and 320° absolute. A. Eucken and F. Hauck. *Z. physik. Chem.* **134**, 161–77(1928).—E. and H. det. sp. heats over a temp. range from 80° to 320° abs. Some of the figures reported are given below, in cal. per g. mol and °K. CO_2: C_p solid: 8.8 at 80°; 13.7 at 210°. C_s (sp. heat in satd. condition) liquid: 18.95 at 220°; 31.1 at 290°. C_v liquid: 10.4 at 230°; 13.35 at 320°. N_2O: C_p solid: 9.45 at 90°; 13.05 at 170°. A: C_s liquid: 10.55 at 90°; 15.30 at 140°. A: C_v liquid: 5.50 at 90°; 3.60 at 180°. C_2H_2: C_s liquid: 18.0 at 100°, 25.0 at 270°. C_2H_6: C_v liquid: 11.45 at 100°; 11.8 at 260°. Liquid air: C_s: 13.7 at 80°; 17.95 at 120°. Liquid air: C_v: 7.8 at 80°; 5.55 at 170°. MeCl: C_p solid: 11.65 at 90°; 15.30 at 150°. MeCl: C_p liquid: 17.45 at 190°; 18.17 at 240°. C_2H_4: C_p solid: 14.80 at 80°; 16.0 at 100°. C_2H_4: C_p liquid: 16.95 at 110°; 18.80 at 170°. *Heats of fusion:* A: 265.2 at 83.6°; CO_2 1900.3 at 215.6°; C_2H_4 699.0 at 103.6.° C_v shows no abnormal variation in the vicinity of the crit. point, while C_p does vary abnormally for all the substances tested. For A, C_v decreases rapidly with increasing temp., and approaches the value $3R/2$ 30° to 40° above the crit. temp. G. Calingaert

An allotropic form of silver. G. Allard. *Compt. rend.* **187**, 223–5(1928).—Cryst. Ag is cubic, face-centered, $a = 4.06$ A. U. A. studies the powder photograph of Ag pptd. from $AgNO_3$ by Cu (cf. *C. A.* **22**, 2108). This Ag is an allotropic form, rhombic-octahedral orthorhombic, $c = 4.23$, $a = b = 3.76$ A. U., $\alpha = 81°30'$. This corresponds to a rectangular parallelopiped unit cell of dimensions 4.23, 4.91 and 5.70 A. U. and with centered faces. The equidistances calcd. agree very well with those observed, and also with those obtained by Roux and Cournot (cf. following abstract). G. Calingaert

X-ray study of the crystal structure of deposits of metal pairs produced by simultaneous electrolysis. Albert Roux and Jean Cournot. *Compt. rend.* **186**, 1733–6 (1928).—The authors have studied by means of x-ray reflection diagrams, the effect of simultaneous deposition of metal pairs upon various metal cathodes. Cd-Ag, Cd-Sn and Cd-Ni, resp., were deposited upon duralumin and Cu-Zn upon steel. In no case were the characteristic spectra of the constituent metals obtained, but always a spectrum which indicated that a solid soln. or an intermetallic compd. had been formed. A. J. King

The crystal structure of some orthorhombic compounds of the type MX_2. I. H. Bräkken and L. Harang. *Z. Krist.* **68**, 123–38(1928).—$PbCl_2$, $PbBr_2$ and $HgCl_2$ belong to space group V_h^{16}. The unit cells contain 4 mols. and have the following dimensions: $PbCl_2$, 4.496, 7.667, and 9.153 A. U.; $PbBr_2$, 4.706, 7.989, 9.475; $HgCl_2$, 4.307, 5.936, 12.667. Possibilities for the at. positions are discussed. L. S. R.

The question of the structure of thallium-α and thallium-β. Harald Perlitz. Univ. Tartu, Esthonia. *Z. Physik* **50**, 433–5(1928).—Data for resistance and vol

changes at the transformation pt. Tl-$\alpha \longrightarrow$ Tl-β and at the m. p. of Tl-β point to the conclusion that Tl-α has a hexagonal close-packed structure, and Tl-β a face-centered cubic (close-packed) structure. Co, changing from hexagonal close-packed to cubic face-centered structure, has an almost identical resistance change, and approx. the same vol. change as Tl. Those metals which have close-packed structures approx. double their resistance on melting, and Tl-β exactly doubles its resistance on melting.

R. J. HAVIGHURST

The deposition of carbon from carbon monoxide and benzine in the presence of iron. ULRICH HOFMANN. *Ber.* **61B**, 1180–95(1928).—A continuation of the study of black carbon crystals (cf. *C. A.* **21**, 1039). In previous work on thermal decompns. of hydrocarbons temps. under 700° could not be employed. With an Fe catalyst C seps. from CO between 400° and 700°, and from benzine from 700 to 900°. The form or previous history of the Fe is without influence. The C samples so obtained were distinctly cryst. as proved by *x-ray analysis*, the grain size increasing with temp. of deposition. Numerous d., chem. and activity tests also depend on temp. The fact that crystals of C can be obtained at so low a temp. indicates formations of a carbide with the Fe with subsequent decompn. The formation of Fe_3C is not proved by x-ray analysis. However, at 400° with CO and at 700° with benzine appear diffraction lines for an unknown substance which is called *X-Carbide*, richer in C than Fe_3C.

G. L. CLARK

The preparation and crystal structure of the mono and diantimonides of palladium. L. THOMASSEN. Univ. Oslo. *Z. physik. Chem.* **135**, 383–92(1928).—A method for prepg. alloys of difficultly fusible and volatile elements is described, and PbSb and $PdSb_2$ are prepd. From the powder diagram it was concluded that PdSb has a Ni arsenide structure with a = 4.070 A. U., c = 5.582 A. U. and $PdSb_2$ has a pyrite structure with a = 6.439 A. U.

M. R. FENSKE

X-ray investigation of the structure of the carbon chains in hydrocarbons (C_nH_{2n+2}). J. HENGSTENBERG. *Z. Krist.* **67**, 583–94(1928).—$C_{35}H_{72}$ is orthorhombic, with 2 mols. in the unit cell of the dimensions a = 7.43, b = 4.97, and c = 46.2 A. U. The CH_2 groups are spaced in the direction of the c axis at intervals of 1.27 A. U. A mixt. of high-mol. paraffins showed the same simple CH_2 spacing. The basic symmetry is orthorhombic, space group V_h^{16}. H. proposes a zigzag arrangement of CH_2 groups, with adjacent C atoms 1.52 A. U. apart.

L. S. RAMSDELL

X-ray investigation of the structure of some naphthalene derivatives. JOHN MONTEATH ROBERTSON. *Proc. Roy. Soc.* (London) **A118**, 709–27(1928).—The crystal structures of 1,2,3,4-tetrachloro-1,2,3,4-tetrahydronaphthalene and of 1,2,3,4,5,8-hexachloro-1,2,3,4-tetrahydronaphthalene examd. by the rotating-crystal method are found to be closely similar. The former has a 7.9, b 10.3, c 14.2 A. U., β 112° 40′, d 1.67; the latter a 7.8, b 12.3, c 13.9 A. U., β 116° 14′, d 1.87. The lattices are monoclinic body-centered with 4 asymmetric mols. in the unit cell, and the most probable space-group is C_s^4. This involves a polar mol. By means of Bernal's method of interpretation, indices are assigned to all the reflections. Information is also obtained as to the approx. location of the halogen atoms, which virtually lie on a different type of lattice. A qual. examn. and comparison of the intensities of the most important reflections indicate that the two addnl. substituted Cl atoms in the hexachlorotetrahydronaphthalene must lie somewhere beneath the other halogens when the structure is viewed along the c axis. The facts are accounted for if it is assumed that the long axis of the mol. coincides with the c axis of the crystal. The intensity distribution in the higher orders of certain planes requires an almost flat C ring, as in the graphite structure.

B. C. A.

The theory of crystal growth. IVAN N. STRANSKI. *Z. physik. Chem.* **136**, 259–78 (1928).—On the assumption that the surface of a crystal has practically the same cryst. structure as the inside of the crystal and that mols., on crystn., tend to go to the place of min. energy, S. calcs. the repulsive forces at various places in the crystal and concludes that in a crystal of the NaCl type only the (100) surfaces are stable, that the surfaces (110) and (111) are (in vacuum) only imaginable as a great no. of cube surfaces which are grouped in dome or pyramid formations, that two-dimensional cryst. kernels are formed on the cube surface on growth, and that the ions or mols. crystallize out most easily on a cube corner, then on an edge, and most difficultly on the middle of a surface. Soln. takes place in the reverse order.

MALCOLM DOLE

Crystal structure information from 1913 to 1926. P. P. EWALD AND C. HERMANN. *Z. Krist.* **65**, Special suppl. 65–96; **66**, 97–224(1927); cf. *C. A.* **21**, 3774.—The structures of the remaining elements are given, and there is a general tabulation of compds. of the type AB. Included are description and references to all structure detns. of compds.

of the type AB; and a general discussion of compds. of the type AB_2, with the first part of the descriptions of this type. L. S. RAMSDELL

Morphotropic families. E. HERLINGER. *Fortschritte Mineral. Kryst. Petrog.* **12**, 43–4(1927).—A brief discussion of morphotropic families and space groups. J. F. SCHAIRER

Crystal orientation in cast plates of metals. RUDOLF VOGEL. *Neues Jahrb. Min. Abt. A, Beil.-Bd.* **53**, 229–40(1926).—Microscopic studies on the orientation of crystals in plates of Pb, Al, Sn, Zn, Cd, Sb and Bi. J. F. SCHAIRER

The loosening, the reactivity and the electrical conductivity of the crystal lattice. J. ARVID HEDVALL. *Svensk. Kem. Tid.* **40**, 65–98(1928).—A detailed review and discussion of the work on elec. cond., lattice type (*i. e.*, ionic or mol.) and loosening of the crystal lattice and their relation to the reactivity of crystals in reactions between solids. R. L. HERSHEY

Toluyl enol. S. RÖSCH. *Fortschritte Mineral. Kryst. Petrog.* **11**, 327–8(1927).—Enolic toluylbenzoylmethane, $C_6H_4MeC(OH)CHBz$, forms orthorhombic tablets $a:b:c = 3.092:1:1.66$. The index of refraction increases from red to violet. $\alpha = 1.635–1.690$, $\beta = 1.644–1.805$, $\gamma = 1.932–2.359$. The birefringence is very strong. J. F. SCHAIRER

The mechanical twinning of zinc crystals. E. SCHMID AND G. WASSERMANN. *Z. Physik* **48**, 370–83(1928).—New observations on Zn crystals extended to the breaking point confirms Mathewson and Phillips (cf. *C. A.* **21**, 1083), *i. e.*, that the secondary extension is due to a secondary translation upon a lattice plane which has been introduced by twinning. The observations were both microscopic and roentgenographic. That the secondary translation is on the basal plane is shown by the six-fold symmetry of a Laue picture taken perpendicular to the translation plane. The actual extension due to twinning is very small compared to the total extension; but the twinning is highly important since it allows the second translation to take place. The mech. twinning appears to cause a sudden increase in tensile strength of the basal translation plane, the increase amounting to approx. a doubling. R. L. HERSHEY

X-ray studies of the nitrides of iron. GUNNAR HAGG. Inst. of Metallography, Inst. of Gen. and Inorg Chem. of the University, Stockholm. *Nature* **122**, 314(1928); cf. *C. A.* **22**, 4056.—Further studies of the nitrides of Fe indicate that in the γ-phase, which was previously reported to be a solid soln., the N atoms have a definite location in the Fe lattice, which for γ-Fe is face-centered cubic. It is tentatively suggested that there is one N atom per unit cell, located either at the center ($^1/_2, ^1/_2, ^1/_2$), or at the position $^1/_4, ^1/_4, ^1/_4$. A. W. KENNEY

Atomic arrangement in crystals of the alkali thiocyanoplatinates. STERLING B. HENDRICKS AND HERBERT E. MERWIN. *Am. J. Sci.* **15**, 487–94(1928).—Laue and spectrum x-ray pictures served to det. the at. arrangement in crystals of NH_4, K and Rb thiocyanoplatinates. The crystals are hexagonal. The units contg. $1R_2Pt(SCN)_6$ have the following dimensions: (NH_4), $a = 6.77$ A. U., $c = 10.45$ A. U.; (K), $a = 6.73$ A. U., $c = 10.26$ A. U.; (Rb), $a = 6.75$ A. U., $c = 10.47$ A. U. The at. arrangement is: Pt at 000; alkali at $\frac{12}{33}v$; $\frac{21}{33}\bar{v}$ with v about 0.50; S, C and N at $u\bar{u}v$; $2\bar{u},\bar{u},v$, $u,2u,v$; $\bar{u},u,\bar{v}$; $2u,u\bar{v}$; $\bar{u},2\bar{u},\bar{v}$, with $u_s = 0.10$ to 0.17, $v_s = 0.09–0.135$; or Pt at 000 alkali at $\frac{1}{3},\frac{2}{3},\frac{1}{2}$; $\frac{2}{3},\frac{1}{3},\frac{1}{2}$; S, C and N at uuv, $o\bar{u}v$, $\bar{u}ov$, $uo\bar{v}$, $\bar{u}\bar{u}\bar{v}$, $ou\bar{v}$, with $u_s = 0.17–0.24$ 0.09–0.135. The S atom in either of the two possible arrangements is adjacent to the Pt atom. R. L. HERSHEY

Röntgenographic studies of manganese arsenide, iron telluride, nickel stannide and platinum stannide. IVAR OFTEDAL. *Z. physik. Chem.* **132**, 208–16(1928).—Specimens of *MnAs*, *FeTe*, *NiSn* and *PtSn* were examd. by the x-ray powder method The prepns. were probably of the general type R_x,M_y, it not being certain that the 2 elements were present in the exact stoichiometric relation. The elementary cells are hexagonal the dimensions being as follows: MnAs, $c = 5.704 \pm 0.006$, $a = 3.716 \pm 0.003$; FeTe, $c = 5.651 \pm 0.005$; $a = 3.800 \pm 0.003$; NiSn, $c = 5.174 \pm 0.003$, $a = 4.081 \pm 0.002$; PtSn, $c = 5.428 \pm 0.005$, $a = 4.103 \pm 0.003$, all in A. U. For MnAs and PtSn the NiAs structure type seems certain; for FeTe and NiSn it seems at least probable. R. L. HERSHEY

The differentiation of right- and left-hand forms with the aid of x-rays. A. HETTICH. *Z. Physik* **48**, 614–5(1928).—X-rays introduce, in the process of diffraction, an apparent center of symmetry into a crystal, so that, as is known, there are only 11 and not 32 symmetry classes distinguishable by x-rays. However, the Laue spots from 2 similarly

placed crystals of the same class and compn., but one right-handed and one left-handed, will not coincide in absolute position. It is suggested that quartz, *e. g.*, its positive and negative edges having been detd. by piezoelectric expts. and hence its position being known, can be detd. as either right- or left-handed by a simple reflection expt. from one of the prism faces. R. L. HERSHEY

The form of crystals of artificial vivianite. G. CESÀRO. *Bull. sci. acad. roy. Belg.* [5], **14**, 260–4(1928).—A fairly large and well-developed clinorhombic crystal of artificial *vivianite* was examd. under the microscope. The principle faces are 010, 100, 403 and 105. The angles between faces are: 100–105, 66°; 100–403, 147°; 105–403, 147°. The principal optical axis is perpendicular to 010. R. L. HERSHEY

Röntgenographic studies of the structure of the oxides of iron. H. GROEBLER. *Z. Physik* **48**, 567–70(1928).—Fe_2O_3 was reduced by CO at 800°. The equil. between the solid phase and CO in the gas phase is plotted. Debye-Scherrer pictures of the variously composed solid phases were taken. The first pictures of prepns. having an FeO content up to 5%, show an expanded Fe_3O_4 lattice; with higher FeO content, the FeO lines themselves appear. The Fe_3O_4 lattice continues to shrink up to about 39% Fe_3O_4; the FeO lattice shows no change up to pure FeO. The last pictures show the FeO lines and the strongest lines of pure Fe. FeO forms a solid soln. with Fe_3O_4 up to 5% FeO, after which it appears as a separate component. Fe is only slightly sol. in FeO under these conditions, since the FeO lattice shows no displacement of its lines in the specimens having free Fe present. R. L. HERSHEY

Growth forms of alum. HANS HIMMEL. *Neues Jahrb. Min. Abt. A, Beil.-Bd* **54**, 88–125(1926).—A study of growth forms of potash-alum crystals with many sketches. J. F. SCHAIRER

Zigzag borders (wrinkled borders) and related polarization forms in crystals and crystal aggregates. F. BERNAUER. *Neues Jahrb. Min. Abt. A, Beil-Bd.* **55**, 92–143 (1926–7). J. F. SCHAIRER

Are the growth phenomena derived from the solution phenomena through the reversal of signs? R. GROSS AND H. MÖLLER. *Neues Jahrb. Min. Abt. A, Beil.-Bd.* 53, 95–133(1926).—Expts. were made on the growth from soln. on polished spheres of halite and sylvite. Parallel growths with corners and projecting angles resulted. A long mathematical discussion of the difference between the forms produced by growth and soln. of crystals is given. Under growth conditions faces in the final form remain smooth and during soln. these become roughened. A formula is derived for the concn. curve of a satd. soln. with decreasing temp. and the formation of crystal nuclei. J. F. SCHAIRER

Deformation structures of aluminum crystals and crystal masses and their reciprocal relations. E. SCHIEBOLD. *Fortschritte Mineral. Kryst. Petrog.* **11**, 25–8(1927).—The effects of crushing, rolling, drawing and torsion on Al crystals were studied. J. F. SCHAIRER

The lattice constant of barium telluride. MAX HAASE. *Z. Krist.* **68**, 119–22 (1928).—BaTe is cubic, and the side of the unit cell was found to be 6.82 ± 0.02 A. U. from a powder photograph taken with Cu radiation and standardized with NaF, or 6.86 ± 0.04 when Mo radiation was used. L. S. RAMSDELL

The crystal structures of monomethyl ammonium chlorostannate and chloroplatinate. RALPH W. G. WYCKOFF. Rockefeller Inst., New York. *Am. J. Sci.* **16**, 349–59(1928).—The at. arrangement in crystals of $(MeNH_3)_2SnCl_6$ has been detd. from a study of Laue and spectrum photographs. The at. grouping is a distortion of the CaF_2 structure. The unit cell is rhombohedral, contains one mol., and has the dimensions $\alpha = 50° 14'$, $a_0 = 8.42$ A. U. The at. arrangement corresponds to space-group 3 Di-5 with the Sn atom at 000, Cl atoms at uuv; uvu; vuu; $\bar{u}\bar{u}\bar{v}$; $\bar{u}\bar{v}\bar{u}$; $\bar{v}\bar{u}\bar{u}$, where $u = 0.225 \pm 0.01$ and $v = 0.26 \pm 0.01$. C and N atoms are at uuu; $\bar{u}\bar{u}\bar{u}$, u_C and u_N being probably about 0.31 and 0.27, resp. Crystals of $(MeNH_3)_2SnBr_6$ and $(MeNH_3)_2PtCl_6$ have very similar arrangements. For the latter, the single-mol. unit cell has dimensions $\alpha = 48° 46'$ and $a_0 = 8.31$ A. U. R. J. HAVIGHURST

The Raman effect in crystals. K. S. KRISHNAN. *Nature* **122**, 477–8(1928).—Monochromatic light scattered from crystals is accompanied by secondary radiation of altered wave length, the difference between incident and scattered frequencies corresponding to a characteristic infra-red frequency of the crystal. When the 4358 A. U. group of the Hg arc is scattered by quartz, the wave lengths of the longest scattered radiations are 118, 94, 78, 48.5, 37.4, and 21.5μ. R. J. HAVIGHURST

X-ray diffraction in solutions and liquid mixtures. I. P. KRISHNAMURTI. *Indian J. Physics* **2**, 501–7(1928).—A tube with Cu anticathode, operated at approx. 40 kv., was used to photograph the x-ray diffraction patterns of NH_4NO_3 and acetamide, both

in powd. form and in aq. solns. of various concns. With concd. solns. the development of an inner ring indicates the existence of a regular space array just as in the liquid or solid states. Unlike concd. acetamide solns., concd. solns. of NH_4NO_3 give a certain amt. of general scattering, probably due to ions distributed at random in the liquid. The 2 rings which appear in the solid state appear also in the liquid state and in very concd. solns., but both of them undergo some contraction. As the diln. increases the inner ring contracts and tends to disappear as a general halation, while the outer ring, if smaller than the ring for H_2O, expands and merges with it as the diln. is increased. Hence the outer ring is considered as a superposition effect due to H_2O and the solute in proper proportions. A no. of excellent reproductions of the radiograms characteristic of the different dilns. are included. W. W STIFLER

Examination of liquids by x-rays by the method of the "rotating crystal." D. COSTER AND J.-A. PRINS. *J. phys. radium* [6], 9, 153-5(1928).—A *special camera for obtaining liquid diffraction pictures* from liquids having heavy atoms has been made. It consists of an x-ray tube, electron type, mounted on a movable arm, the axis of rotation being horizontal and lying in the surface of the liquid to be examd. A small cylindrical camera is fastened to the end of the x-ray tube, its axis coinciding with the axis of rotation. The procedure is to place the liquid, in a suitable tray, within the camera, and expose the film with different angles of incidence between the liquid surface and the x-ray beam. A greater effective intensity of the diffracted beam is thus obtained than by the usual method. Hg has been examd. and reveals 3 amorphous rings. R. L. HERSHEY

The molecular forces in crystal growth. W. KOSSEL. *Physik. Z.* 29, 553-5 (1928).—The rate of crystal growth is studied in relation to the energy released when an atom or an ion is added to the lattice. Such an addn. may be made in 3 ways: to the end of a row of atoms; to the edge of an uncompleted plane of atoms; and to the surface of a completed plane. Two cases are considered, those of homopolar and heteropolar crystals. In the first a cubic lattice is assumed and the effects of the 26 nearest neighboring atoms are considered and the relative magnitudes of the energies for the above three cases are calcd. It is apparent that the (100) faces will grow less rapidly than the (110) and hence will persist in the crystal form. Similar considerations for the 100 faces of a heteropolar crystal such as NaCl show that on these faces growth is in the following order, uncompleted rows are completed, a new row is started and completed, etc., until the plane is complete, the next atom. is added on the surface of this plane and the cycle begins over. Thus (100) faces grow as true planes. (110) faces, however, grow as a series of ridges formed by the junctions of (100) planes. These ridges have alternately positive and negative ions on their edges. The intervening space between ridges is not filled to form a true (110) face, since this would require the placing of ions exactly between 2 others of like sign. R. L. HERSHEY

The crystal as a homogeneous polyhedron. J. BECKENKAMP. *Neues Jahrb. Min. Abt. A, Beil.-Bd.* 54, 1-71(1926); cf. *C. A.* 21, 679.—Axes of rotation L' of 360° and L'' of 180° are of 2 kinds, the second kind involving an alternating reflection or an inversion center. The 32 crystal symmetry-classes are derived. The derivations and nomenclature are too long to present in an abstract. J. F. SCHAIRER

The equilibrium between methylate and hydroxyl ions in mixtures of methanol and water. II. Investigations by means of electrometric hydrogen-ion measurements. AUGUSTA UNMACK. *Z. physik. Chem.* 131, 371-88(1928); cf. *C. A.* 22, 1715.—The H-ion activity in mixts. of MeOH, H_2O and methylate of K or Na at 18° was detd. by e. m. f. measurements on cells of the type

$$H_2 \left| \begin{matrix} CH_3OH \\ KOH, KOCH_3 \\ H_2O \end{matrix} \right| KCl(3.5N) \mid KCl(0.1N) \mid HgCl \mid Hg$$

The concns. of methylate used were 0.1, 0.01 and 0.00333 M, while the concn. of MeOH varied from 0 to 24.9 M. The equil. const. of the reaction $OH^- + CH_3OH = OCH_3^- + H_2O$ was calcd. to be about 0.47. E. R. SMITH

X-ray diffraction and its bearing on the molecular complexity in the liquid state. P. KRISHNAMURTI. *Indian J. Physics* 2, 491-500(1928).—X-ray diffraction patterns were photographed for 26 pure org. liquids. In every case in which the surface tension method indicated mol. assocn., the photographs showed a prominent inner ring. When the Ramsay-Shields formula for computing the degree of assocn. from surface tension data is modified by substituting x-ray values for the spacing in place of m/d, the results for these liquids are much more probable and certain anomalous values previously obtained are rectified. Nearly all the liquids examd. showed assocn. to some extent and it is suggested that these can be treated as solns. of double or triple mols. in a solvent com-

posed of single or double mols., resp. A no. of excellent reproductions of the x-ray diffraction patterns are included. W. W. Stifler

The crystalline liquid state as a general property of matter. I. Vectorial aggregation, fluid structure and stream-double refraction of barium sulfate ultramicrocrystals. P. P. von Veimarn. *Kolloid-Z.* **44**, 279–88(1928).—The results of a microscopical and ultramicroscopical examn. of $BaSO_4$, pptd. by mixing concd. solns. of $MnSO_4$ and $Ba(CNS)_2$, support V.'s claim that the state of aggregation of the ppt. depends not so much on the properties of the pptd. substance as on the physicochem. conditions of pptn. Five stages can be distinguished in the pptn. of $BaSO_4$: (1) chem. reaction, (2) formation of highly supersatd. and assocd. soln. of $BaSO_4$, (3) production of very concd., highly disperse colloidal soln., (4) vectorial aggregation in this colloidal soln., (5) destruction in consequence of aggregative crystn. (formation of larger ultramicro- or micro-crystals). An increase in viscosity occurs during the processes (1) to (4), the substance changing from a thick oil of sirupy consistence to a gelatinous membrane. With $BaSO_4$, states (1) and (2) are passed through rapidly. B. C. A.

The crystal class of the pentaerythritols and the tetrahedral carbon atom. A. Schleede and A. Hottich. *Z. anorg. allgem. Chem.* **172**, 121–8(1928); cf. *C. A.* **22**, 895.—By means of Meissner's method for the detection of piezoelec. charges and etch figures produced with MeOH the pentaerythritols are shown to belong to the tetragonal system with bisphenoidal symmetry S_4. The pentaerythritol mol. is not pyramidal but tetrahedral and remains completely in harmony with the classical stereochemistry of van't Hoff and Le Bel. Claim is made that the only exptl. support for the existence of pyramidal mols. of the methane type is in error. The geometric stereochem. system of Weissenberg, held to be general, must be limited. H. W. Walker

X-ray study of some simple ethane derivatives. I and II. (Miss) K. Yardley. *Proc. Roy. Soc.* (London) **A118**, 449–84, 485–97(1928).—I. A detailed investigation has been made of crystals of C_2Cl_6, C_2Br_6, $C_2Cl_4Br_2$ (two forms), C_2Br_5F, $C_2Cl_3Br_3$ and $(MeCBr_2)_2$ (two unstable orthorhombic forms, one obtained below 0°). These substances form an isomorphous series, crystg. in the space-group Q_h^{16}. C_2Cl_6 has $a\ b.c$ = 1.1350:1:0.6302; C_2Br_2, $a:b:c$ = 1.1278:1:0.6270; $C_2Cl_4Br_2$ (symmetrical form), $a:b:c$ = 1.1308:1:0.6270; (asymmetrical form), $a:b:c$ = 1.1220:1:0.6288; C_2Br_5F, $a:b:c$ = 1.1012:1:0.6098; $C_2Cl_3Br_3$, $a:b:c$ = 1.1270:1:0.6262; $(MeCBr)_2$ (low-temp. form), $a:b:c$ = 1.073:1:0.601; (ordinary-temp. form), $a:b:c$ = 1.1206:1:-0.6296. There are 4 mols. in the unit cell, each possessing a plane of symmetry parallel to (010). This plane passes through the 2 C atoms and two of the halogen atoms (or the 2 Me groups in $(MeCBr_2)_2$), with the other 4 halogen atoms arranged in pairs on either side. In C_2Cl_6 and C_2Br_6, and probably in $(MeCBr_2)_2$, the mols. also possess a pseudo-center, which produces additional halvings not expected from space-group considerations. The symmetry of the C valencies is deduced from the mol. symmetry and it is shown that the C atom possesses 2 A and 2 B valencies, possibly identical with the two (2,1) and two (2,2) electrons in the outer group of neutral C. Composite *F* curves obtained for C_2Cl_6 and C_2Br_6 are compared with Hartree's curves for Cl^- and C^{++++} (cf. *C. A.* **19**, 2910). The formula of both forms of $C_2Cl_4Br_2$ appears to be $CCl_3.CClBr_2$. II. $(MeCBr_2)_2$ possesses a stable tetragonal form, which bears no apparent resemblance to the 2-forms described above, and has *a* 8.80₆, *c* 11.27 A. U. d 2.818. The unit cell probably contains 4 mols. in face-centered positions. $(Me_2CBr)_2$ forms needle-like tetragonal crystals having $a:c$ = 1:0.7798 and d. 1.811. There are 4 mols. in the unit cell occupying approx. face-centered positions, and possessing either a plane or dyad axis of symmetry or both. The mols. themselves simulate tetragonal symmetry. There are 2 possible types of structure, which are illustrated. $Me_3CCBrMe_2$ forms needle-like crystals very similar to those of $(Me_2CBr)_2$. The orthorhombic cell has *a* 21.35, *b* 10.77, *c* 7.84 A. U., d. 0.85; it may be divided into two pseudotetragonal parts, the arrangement of mols. in each resembling that in the unit cell of $(Me_2CBr)_2$. The space-group is C_{2v}^{21}. B. C. A.

Radiate crystallization. B. Popov. *Fortschritte Mineral. Kryst. Petrog.* **11**, 320–1(1927).—The phenomenon of radiate crystn. was investigated with *malonamide* and *resorcinol*. J. F. Schairer

So-called rhythmic crystallization. F. Bernauer. *Fortschritte Mineral. Kryst. Petrog.* **12**, 14–5(1927).—A discussion of types of rhythmic crystn. with examples for demonstration. J. F. Schairer

Diffusion rings and crystallization rings. G. Linck and E. Korinth. *Z. anorg. allgem. Chem.* **171**, 312–6(1928).—S was dissolved in CS_2 thickened with Canada balsam or rubber. Upon dilg. the soln. a cloud of droplets of S appears, the larger droplets

growing at the expense of the smaller, and some finally becoming surrounded by a space entirely free of droplets. The phenomenon is more striking in case a crystal of S forms, for it rapidly absorbs all the droplets in the immediate neighborhood and, as it grows, droplets at the edge of the clear space gradually dissolve and the space grows in extent. The droplets apparently move toward the crystal, dissolving on the way. An apparently new tetragonal modification of S was identified in the course of the work. This new modification spontaneously transforms into a second bright yellow liquid modification. R. L. HERSHEY

The effect of nitrocellulose upon the velocity of crystallization of gelatinizing solvents. ANNIE MILLICENT KING. Univ. of Bristol, Eng. *Trans. Faraday Soc.* **24**, 453-62(1928).—The linear velocity of crystn. of solns. of nitrocotton in concns of 0.2-2% in benzophenone, phenylurethan, diphenylurethan and formanilide was measured. The nitrocotton contained 0.27% ash, 12.10% N, and was 99.45% sol. in alc.-ether mixt. For benzophenone, the rate of crystn. was lowered by increase in concn. of nitrocotton. With diphenylurethan the phenomenon of polymorphism complicates measurements. The α-form has the highest rate, the γ the lowest. Innoculation of the solns. was necessary, and there was interference by spontaneous crystn. from point sources along the tube. Phenylurethan showed 3 forms, but it was not possible to isolate the α form. Formanilide showed 2 forms. From previous unpublished data on triphenyl phosphate, ethylphenylurethan, *o*-tolylurethan and benzyl formanilide with the results of above measurements, it is concluded that the extra time taken for crystn. in the presence of nitrocotton is exactly parallel to the reputed *gelatinizing power* of the solvent. ARTHUR FLEISCHER

Relation between water and salts in crystalline hydrates and in solutions. J. N. RAKSHIT. *Z. Elektrochem.* **33**, 578-81(1927); cf. *C. A.* **20**, 3118.—The mol contraction observed when a salt forms a cryst. hydrate or a soln. with water has been detd. for various salts. The values obtained for solns. are generally greater than those for the cryst. hydrates and increase notably with diln., but for concd. (including super-satd.) solns. of NaOAc the mol. contraction is less than for the trihydrate, and for $MnSO_4$ solns. it is almost negligible compared with the values for the cryst. hydrates. For solns. of Na_2SO_4 and of Na_2CO_3 at various concns., the mol. contraction has been measured at various temps. between 15° and 90°, but no indication of transition points corresponding with dissocn. of definite hydrates is obtained. It is inferred that the relation between the salt and water in solns. is different from that in the cryst. hydrate B. C. A

The equation for quantizing a molecule composed of *n* electrified particles. TH DE DONDER. *Bull. sci. acad. roy. Belg.* **13**, 756-67(1927).—Using his method (*Ibid* **13**, 693(1927)), D. obtains the Schrödinger equation generalized to apply to a mol. with interaction. The equation is relativistic and additive. F. R. B.

Tensile properties of crystals of an "ennobled" aluminum alloy. R. KARNOP AND G. SACHS. *Z. Physik* **49**, 480-97(1928); cf. *C. A.* **21**, 1730.—Single crystals of an alloy contg. approx. 95% Al and 5% Cu were prepd. by straining and heating wires of the alloy. The orientation was detd. by Laue photographs, the (111) direction being the preferred direction of growth; none was oriented in the (110) direction. Most of the crystals were quenched from 525° in H_2O and annealed at 100°; the others were cooled slowly from 525°. In tensile tests the quenched ("ennobled") crystals behaved like Al crystals so far as slip was concerned. Four crystals were examd for orientation, after break, by the rotating-crystal method and found to agree very closely with the orientation predicted from the slip mechanism of Al. In the tensile tests the load at the beginning of slip varied from 18 to 36 kg./mm.² for the quenched crystals and depended upon orientation; the "effective tension" on the glide plane, however, was const. at 9.3 kg./mm.² with a mean deviation of ±8%. In the unquenched crystals the variety of orientation was not so great and the tension *vs.* cross section decrease curves were better grouped. The type of break depends upon the orientation as follows: the break for orientations in the region between (111), (100) and (110) is a single flat surface, which in the unquenched crystals was inclined at approx. 45° to the wire axis, and in the quenched crystals at angles depending on the orientation; with orientations approx. along (111) several plane surfaces appeared on the break, the angles between having no apparent significance; with orientations along (100) no plane surfaces appeared on the break, but like an ordinary wire, a decided drawing. Laue pictures of quenched and unquenched crystals show only sharper spots and slightly less asterism for the unquenched. The tensile properties are greatly changed by quenching, the "effective tension" on the glide plane increasing from 2 to 9.5 kg./mm.² The extension is not greatly different. The unquenched crystals recrystallize at

330–340°; the quenched at 450–470° and in larger crystals than the unquenched. The change in properties with quenching is apparently due to a particular state of the crystal lattice. R. L. HERSHEY

Single crystals of iron. IV. Dependence upon temperature of the magnetization of single crystals of iron. ERNST DUSSLER. Tübingen. *Z. Physik* **50**, 195–214 (1928).—The magnetization of single crystals of Fe, parallel to the digonal and tetragonal axes, was investigated at various temps. between liquid air and the Curie point. For all temps. the magnetization curves were essentially similar, consisting of an initial linear ascent, the slope of which is *independent* of the temp., which goes over with a sharp, definite break into the part of the curve corresponding to satn. The height of this break, and therefore the satn. value of the magnetization decreased with increasing temp. apparently according to an exponential law. At higher temps., satn. is reached at lower fields. It has the same value for both crystal directions, although it is reached at lower fields for the tetragonal than for the digonal direction. W. W. STIFLER

Studies of physical purity by means of x-ray powder diagrams. N. H. KOLKMEIJER. *Z physik. Chem.* **136**, 45–8(1928).—See *C. A.* **22**, 1066, 2500. R. L. H.

Direct determination of Thomson coefficients in single-crystal zinc rods. L. A. WARE. State Univ. of Ia. *Proc. Iowa Acad. Sci.* **34**, 282(1927).—The Thomson coeffs. for a single crystal of Zn as a function of the orientation of the principal cryst. axis are being directly detd. by Nettleton's method. For a rod with an orientation angle of approx. 45°, the coeff. shows a rise with increasing temp. over the range 50–250°. W. G. GAESSLER

Determination of specific gravity of powders. H. RASQUIN. *Farben-Ztg.* **33**, 1786–7(1928).—The sp. gr. of powders insol. in and heavier than water is detd. by introducing 10 g. of the substance through a funnel into 10 cc. of water in a measuring cylinder, the exit tube of the funnel being kept just clear of the water. The sp. gr. is found by dividing 10 by the increase in vol. in cc. B. C. A.

Further observations on sulfur and selenium. E. KORINTH. Mineralogy und Geol Inst., Jena. *Z. anorg. allgem. Chem.* **174**, 57–60(1928).—Crystn. of S from $CHCl_3$ soln. to which have been added rubber as a thickening agent and a few drops of benzonitrile, yielded several new forms. The least stable of these is the δ-modification, found to be identical with that described by Muthmann. It crystallizes as small, flat, hexagonal pyramids, nearly colorless, with angles between 119.5° and 121°. They are weakly birefringent and are extinguished parallel to one edge. In convergent light there is a lateral emergence of one optical axis of a biaxial crystal. This is easily transformed into the ζ-modification, crystg. as rhombic tablets, birefringent, colorless and extinguished parallel to the diagonal. The greater coeff. of refraction lies in the direction of the short diagonal. The crystals are biaxial, with one axis extinguished obliquely to the tablet face. The rhombus angles av. 64° 30′. Another form obtained is the η-modification, crystg. in hexagonal tablets with unequal angles. Those on the long edge vary between 122° 45′ and 122° 12′, while the others vary between 114° and 115° 36′. These crystals are only faintly colored, are birefringent and extinguished parallel to the long edge. These modifications of S are arranged as follows in the order of increasing stability: ϑ-tetragonal ⟶ δ-monoclinic ⟶ η-monoclinic ⟶ ζ-monoclinic ⟶ γ-monoclinic ⟶ β-monoclinic ⟶ α-rhombic. If a soln. of red amorphous Se in CS_2 is evapd., small hexagonal crystals sep. (about 50μ in size) which are yellow to reddish brown, transparent, birefringent, with extinction direction parallel to the longer side of the hexagon. They are monoclinic and are found to be isomorphous with the η-modification of S. If these crystals are added to a soln. of S, S is deposited on the Se crystals leading to a layer crystal of isomorphous S and Se. If only a little Se soln. is added to a S soln. such as described above, the η-modification of S is formed almost exclusively; examn. of the S crystals under high magnification, however, reveals the presence of tiny Se particles in the S crystals, demonstrating the conditioning effect of Se upon the crystal form of S. H. STOERTZ

The specific gravity of glycerol. L. W. BOSART AND A. W. SNODDY. *Seifensieder-Ztg.* **55**, 242(1928).—A correction to Prager's article (*C. A.* **22**, 1865) in which he says that the actual glycerol content is usually 0.2% lower than Gerlach's table shows that the Bosart-Snoddy table is throughout higher than Gerlach's. B. and S. show by an example that their values are usually somewhat lower than Gerlach's and that the latter's table is hardly accurate today. P. ESCHER

The reaction of liquids. L. W. HAASE. *Kl. Mitt. Ver. Wasserversorg. Abwässerbeseitig.* **3**, 281–98; *Chem. Zentr.* **1927**, II, 2328.—A discussion of subjective (chiefly optical) and objective (elec.) methods for the practical detn. of the reaction of liquids. The elec. methods have outstanding advantages. C. C. DAVIS

Theory of the extinguishing collisions between the dissolved molecules in viscous solutions. M. Leontovich. *Z. Physik* **50,** 58–63(1928); cf. *C. A.* **22,** 4375.—By a more rigorous treatment than that of Vavilov, an exact formula is worked out for i. This is $i = [{}^1/_{24}NcD\sigma][1 + (2D/v\sigma)]$, where N is the no. of mols. per cc., D the diffusion coeff., and σ the radius of the solute mol. G. M. Evans

New binary azeotropes. VI. Maurice Lecat. *Ann. soc. sci. Bruxelles* **47B,** I, 63–71; *Chem. Zentr.* 1927, II, 904–5; cf. *C. A.* **22,** 1712, 2722.—A continuation of the previous investigations of 142 systems. Of these, 52 formed pos. and 4 formed neg. azeotropes, 42 formed eutectics (water with 36 esters and 6 ethers) and the rest were not azeotropic. The following are to be emphasized: *Me borate,* m. 68.75°, forms an azeotrope with *MeOH,* b. 55–6°, which has been mistaken for Me borate; it further forms azeotropes with *n-hexane, isobutyl chloride, propyl bromide* and *acetone.* The b. ps. of various mixts. and their components are given as follows: 59% *acetone* (56.35°)—*n*-hexane (68.95°) = 49.8°; 88.5% acetone—CCl_4 (76.75°) = 56.28; 48% acetone—*methyl acetate* (56.25°) = 55.7°; 87% acetone—*chloromethyl ether* (59.15°) = 56.1°. CS_2 forms azeotropes with chloromethyl ether, *tert-butyl chloride, propyl chloride, ethylidene chloride* and *isopentene.* About 85% Me_2S (37.3°)—MeOH (64.7°) = 34°; 44% Et_2S (92.2°)—*EtOH* = 72.6°; 68% *furfurole* (161.45°)—*cymene* (176.7°) = 157.8°; 8% *glycol* (197.4°)—*bromoform* (149.3°) = 146.5°; *sec-octanol* (179°)—*benzyl chloride* (179.3°) = 176.5°; 90% *prim. n-octanol* (195.15°)—*benzal chloride* (205.15°) = 194.5°; 6% EtOH—propyl chloride (46.65°) = 45°; 30% acetone—ethylidene chloride (57.25°) = 57.55°. When a few drops of diethylamine are added to about 20 cc. CS_2 a violent reaction ensues with the formation of colorless crystals, m. 78°, with an odor of mustard oil. The nature of this product has not been detd. J. S. Reichert

Crystalline structure of benzene. E. Gordon Cox. Davy Faraday Research Lab. *Nature* **122,** 401(1928).—X-ray rotation method upon single crystals shows unit cell of benzene crystal to be simple orthorhombic, and to contain 4 mols. a = 7.44 A. U., b = 9.65 A. U., c = 6.81 A. U. at −22°. Space group is Q_h^{16} (orthorhombic bipyramidal). In *the crystal* the mol. has a center but no plane of symmetry. A. P. S.

Structure of thin films. XI. Oxygenated derivatives of benzene. N. K. Adam. *Proc. Roy. Soc.* (London) **A119,** 628–44(1928); cf. *C. A.* **22,** 1713.—Although many alkyl, acyl and ether derivs. of resorcinols and phloroglucinols have been examd. with a view to measurement of the cross section of the benzene ring, none has been found exactly suitable. The attraction of multiple hydroxyl groups for neighboring mols. outweighs their attraction for water and most of such rings stand upright. Only compds. with a resorcinol group at each end of a long carbon chain, and *humulone,* having three chains on the ring, could be said to lie flat, and in these cases the size and shape of the mol. prevented measurements of the ring itself. **XII. Cholesterol and its effect in admixture with other substances.** N. K. Adam and G. Jessop. *Ibid* 473–82.—Cholesterol and some simple derivs. form condensed surface films and condense films of substances which normally form liquid expanded films, though gaseous films are not completely condensed. As there is no detectable attraction by the cholesterol mols., and as some other large mols. partially share the condensing property, it is probably due to mechanical obstruction by the large mols. of the oscillations of the smaller ones. G. M. Evans

Glass. II. The transition between the glassy and liquid states in the case of glucose. George S. Parks, Hugh M. Huffman and Francis R. Cattoir. Stanford Univ. *J. Phys. Chem.* **32,** 1366–79(1928); cf. *C. A.* **22,** 1259–60.—A clear glass made by cooling melted cryst. glucose softens at 40° and becomes a viscous liquid at 60°. The sp. heat of this material increases 62% between 275° and 287° K. and has been measured between 90° and 340° K. The coeff. of thermal expansion increases 200% over the range 293–303° K. and has been measured from 262° to 348° K. The n shows a decided change from 20° to 30° and has been measured within the interval 7–77°. Aside from these irregularities the slopes of the curves are smooth. Theoretical discussion is reserved for a later communication. W. T. Richards

Adhesion of mercury to glass. W. C. Baker. *Science* **67,** 74–6(1928); *Science Abstracts* **31A,** 329.—The adhesion of Hg to glass was measured by means of a planoconvex lens suspended from the arm of a balance. The lens was lowered into a quantity of Hg, kept at const. level, and the diam. of the circle of contact was measured by a microscope and micrometer scale, and from this measurement the height of the apex of the meniscus above the pool of Hg was calcd. Measurements made with different circles of contact and with different lenses all led to the magnitudes to be expected from the known consts. of Hg. H. G.

Measuring with approximation the absolute size of pores. M. A. RABINOVICH AND N. S. FORTUNATOV. Kiev Polytech. Inst. *J. Chem. Ind.* (Moscow) **5**, 689–94 (1928).—The porosity of technical materials is usually characterized as *relative vol. of pores; viz.*, the ratio of the total vol. of the pores to the total vol. of the body. The relative vol. of pores reveals nothing about the real size of the pores. Yet, for the technological characterization of materials, the knowledge of the *abs. size of pores* would be valuable. *E. g.*, if the porous substance is a carrier (bearer) of great surfaces, it is by no means indifferent what the abs. size of pores is; the "*specific surface*" of the substance is the greater the smaller the pores, the porosity remaining const. Again, the *mechanical strength* of the materials certainly depends on the ratio between the av. size of the pores and their no. in a unit of vol. Finally, the abs. size of pores undoubtedly has an interest in the characterization of *diaphragms* in electrochem. processes and in many other cases. Considering the structure of porous bodies as a system of communicating capillary cylinders, R. and F. proceeded to det. the av. radii of the pores for various parts of vol. porosity; their method was based on the investigations of Zsigmondy (*C. A.* **11**, 2302), Anderson (*C. A.* **8**, 3141) and W. Bachmann who calcd. the dimensions of capillary pores of gels from the data obtained by detg. vapor pressures in the processes of hydration and dehydration of gels. Minkovskii's equation was modified thus: $r = K/(\log P_0 - \log P_1)$, where K is a const., P_0 vapor pressure over the flat surface and P_1 vapor pressure over the meniscus in the capillary pore, and it was assumed that $P_0 - P_1$ is not less than 0.05 mm. The radius to be measured is the greater the greater the const. K, which, in turn, increases with the decrease of temp., the values of K were detd. for 3 different temps. The app. used by R. and F. is described in detail and a drawing of it is given. Tables are given which contain all the data obtained in the detns. of Ural pine charcoal, Ural birch charcoal, activated charcoal, an American graphite electrode, a German graphite electrode, kaolin ignited at 900°, hard porcelain ignited at 1410°. In the order of decreasing relative vol. of pores the charcoals ranged themselves thus: birch charcoal, pine charcoal, activated charcoal; yet the porosity detns. show that activated charcoal is really the most porous of the 3, birch charcoal second and pine charcoal third. Parallels were also drawn between the 2 graphites and between the kaolin and the porcelain. In connection with the above expts. attention is drawn to the following analogy. Von Bemmeln and Bachmann have shown that the greater the age, and consequently the surface, of a gel, the less the vapor pressure beginning with which the irreversible processes of hydration and dehydration take place (*hysteresis*). For old gels the range of hysteresis begins with high values for vapor pressure, the water content being low; the range of hysteresis is in that case very small, and sometimes practically nil. These expts. with detns. of vapor pressures show that, for ignited porcelain, the hysteresis begins higher than for kaolin, and the range of the second is far greater than that of the former. The process of ignition at high temp. evidently leads to the same *changes in the structure* of the porous material as those which were observed in the process of aging of gels. BERNARD NELSON

Displacement of liquids in capillaries. J. L. SHERESHEFSKY. Mellon Inst. Pittsburgh. *Nature* **122**, 312(1928).—If one places in a capillary glass tube drops of 2 immiscible liquids, end to end, so as to form a liquid-liquid interface, the continuous bubble made by the 2 liquids will move in the direction of the liquid with greater surface tension. By raising the end of the tube toward which the bubble is moving to a certain height above the horizontal, equil. is produced and the bubble becomes stationary. If a capillary be so constructed that its ends are joined to tubes of a large cross-section where capillarity is not displayed, and if the ends of the liquid column extend into these tubes, then the liquid-liquid interface which is in the capillary will move in the direction of the liquid of smaller surface tension. This phenomenon may be used in measuring interfacial tension, angles of contact and adhesion tension of liquids against glass. R. J. HAVIGHURST

Surface tension of non-aqueous salt solutions. P. P. KOSAKEVICH. *Z. physik. Chem.* **133**, 1–14(1928).—By means of the capillary-rise method, the surface tensions of a large no. of non-aq. salt solns. have been measured, the solvents including aliphatic alcs., acids and ketones, glycerol, pyridine and furfuraldehyde. The surface tension of the pure solvents is raised by the addn. of salts. For concd. solns. the relation between the surface tension (γ) and salt concn. (C) is linear. For more dil. solns., 3 types of $\Delta\gamma$-C curves are found: (1) concave to the C-axis (chiefly Et and Pr alcs.); (2) convex to the C-axis (MeOH); (3) a straight line passing through the origin (chiefly non-alc. solvents and isoamyl alc.). The greatest neg. capillary activity is observed for salt solns. in MeOH; the value rapidly decreases with increase in the length of

the carbon chain in the homologous alc. series. This phenomenon may be connected with the greater degree of assocn. of salts in the higher alcs. In non-alc. solvents, the neg. capillary activity is found to vary but little. If the angle between the $\Delta\gamma$-C line and the C-axis is taken as a measure of the neg. capillary activity, the order of the alkali metals (in MeOH and EtOH) is the same as that in water, *viz.*, Li > Na > K. By direct comparison of the $\Delta\gamma$ values at equal concns. of the alkali iodides, however, different results are obtained according to the chosen concn., since the curves intersect one another. The order of the lyotropic series Cl > Br > I appears to be reversed in non-aq. solvents. B. C. A.

The rate of evaporation through surface films. RAYMOND BARTLETT AND THOS. C. POULTER. Ia. Wesleyan Col., Mt. Pleasant. *Proc. Iowa Acad. Sci.* **34,** 214–5 (1927).—The purpose was to study the influence of surface tension on the rate of evapn. of H_2O through surface films. The rate of evapn. of pure H_2O and H_2O from solns. of Ca and Na chlorides of concns. varying from 0 to nearly satn. were detd. These 2 solns. were selected because of the tendency of Ca to increase the surface tension and of Na to decrease the surface tension in H_2O solns. A mixt. of these salts was also studied because of the tendency of one to overcome the effects of the other on the surface tension. The 2 curves for the rate of evapn. of Ca and Na solns. were detd. and an increase in concn. caused a decrease in the rate of evapn. from each soln. The detns show a slight increase in the rate of evapn., thereby indicating that the rate of evapn. is influenced to a small degree by the surface tension of the liquid. W. G. G.

Surface actions in chemical phenomena. RENE DUBRISAY. *Bull. soc. chim.* **43,** 625–41(1928).—A review of surface phenomena, especially adsorption, with bibliography. LUCY K. PICKETT

A micro method for the determination of vapor pressure and water of hydration of solid compounds. FRANK E. E. GERMANN AND O. B. MUENCH. Colorado Univ. *J. Phys. Chem.* **32,** 1380–6(1928).—The method described consists in introducing solns of H_2SO_4 in dishes in the tightly closed case of a very sensitive assay balance, with sample painted from a satd. soln. of the salt to be investigated on a microscope cover glass. The loss or gain of wt. and the equil. wt. are then ascertained. An estimate of the vapor pressure of the salt may be thus obtained without loss of material and with the use of exceedingly small quantities. The vapor pressures so obtained may be related to heats of hydration through the Clausius-Clapeyron equation. W. T. RICHARDS

Vapor pressure of benzene-cyclohexane mixtures. N. N. NAGORNOV. *Ann. inst. anal. phys. chem. (Leningrad)* **3,** 562–83; *Chem Zentr.* **1927,** II, 2668.—The vapor pressures of C_6H_6-cyclohexane mixts. from 120 to 765 mm. of Hg were detd. by the dynamic method. The C_6H_6 had f. p. 5.43° and b_{760} 80.0° (thermometer in vapor), whereas the cyclohexane was less pure, with f. p. 6.43° and b_{760} 80.7°. When the pressure (P) is expressed in mm. of Hg (reduced to 0° and 45° latitude), the following expressions apply to pure C_6H_6: $\log P = 7.00380 - 1263.5/(226.44 + t)$; to pure cyclohexane: $\log P = 6.95541 - 1263.3/(229.36 + t)$; to a mixt. of 80.74% C_6H_6 + 19.26% cyclohexane (by wt.): $\log P = 6.90511 - 1214.5/(223.60 + t)$; to a mixt contg. 58.95% C_6H_6: $\log P = 7.05619 - 1305.8/(235.27 + t)$; to a mixt. contg 50.36% C_6H_6; $\log P = 6.96473 - 1253.3/(229.59 + t)$; to a mixt. contg. 40.60% C_6H_6: $\log P = 6.93436 - 1238.6/(228.01 + t)$; to a mixt. contg. 20.30% C_6H_6: $\log P = 6.87934 - 1213.8/(225.07 + t)$. From these data were calcd. by the method of Duhem-Margules the partial pressures of C_6H_6 and cyclohexane at various temps. The compn. of the vapor over the mixt. contg. 40% C_6H_6 changes hardly at all with change of temp The relative C_6H_6 content of the vapor over solns. rich in C_6H_6 increases with increase of temp., and the relative C_6H_6 content of the vapor over solns. poor in C_6H_6 diminishes with increase of temp. The *heats of vaporization* of the mixts. and of the components when evapd. from the mixts. were also calcd. The heats of vaporization of the pure substances were somewhat too great. Mixing C_6H_6 with cyclohexane is endothermic, and the heat tone of the mixing is —166 cal. (20°) per 0.5 mol. The undecompd mixt. b_{760} 77.44°. C. C. DAVIS

• **The viscosity of mercury.** S. ERK. *Z. Physik* **47,** 886–94(1928).—Poiseuille's law, that the speed of a flowing stream relative to the boundary wall is zero at the boundary layer, is applied to Hg since it does not wet surfaces. Recently Tammann and J. Hinnuber (*C. A.* **22,** 707) using metal capillaries have obtained results differing by several hundred percent from the hitherto accepted values. The results of Warburg, Bénard, Koch, Schweidler, Fawsitt, Fenninger and Plüss are compared. Values are given for the viscosity of Hg from —20° to 340°. S. L. B. ETHERTON

The viscosity of glycogen and some dyestuffs and a relation between gelation and

double refraction. S. N. Banerji and N. R. Dhar. Allahabad, India. *Kolloid-Z.* **46**, 24–6(1928).—The viscosities at 30° of solns. of the following dyestuffs decrease when small quantities of electrolytes are added: ponceau red, Victoria blue BA, Victoria blue B, dianil blue B, Bordeaux B extra aniline brown, dianil orange G. The viscosity of glycogen in 5% soln. is greater than is usual for hydrophobic colloids. On aging the viscosities of glycogen soln. and of Bordeaux B extra increase very slightly. Solns. of the following dyestuffs exhibit double refraction on streaming: methyl orange, patent scarlet, imperial green, tropaeolin D, theonine, mercury sulfosalicylate, orange III, orange N. R II, aniline orange. Many of these dyestuffs form jellies. High viscosity, strong hydration, tendency to gelation and double refraction depend upon the non-spherical shape of the dispersed particles. F. L. Browne

The viscosity isotherm of binary mixtures. G. Tammann and M. Elizabeth Pillsbury. *Z. anorg. allgem. Chem.* **172**, 243–55(1928).—A comprehensive survey is given on the viscosity isotherms with varying compn. for 56 binary mixts. of org. compds. These mixts. are classified into 4 groups with reference to the shape of the viscosity isotherm, its displacement with temp., and the nature of the phase diagram. (1) A max. appears on the viscosity curve and the m. p. curve. (2) No max. occurs on the viscosity curve and on the phase diagram no compd. crystallizes from the binary liquid mixt. (3) A compd. crystallizes from the binary liquid mixt., but there is no max. (4) On the viscosity curve there is a pronounced max., but on the phase diagram no compd. crystallizes. A binary mixt. of acetophenone and $SbBr_3$ is an example of case (1). In case (2) belong the isomorphous substances which form an interrupted series of mixed crystals, *e. g.*, p-$C_6H_4Br_2$-p-$C_6H_4Cl_2$, p-$C_6H_4Br_2$-p-C_6H_4BrCl, and p-$C_6H_4Cl_2$-p-C_6H_4BrCl, and also the substances which form a eutetic. Six examples of the third case and seven of the fourth case are known. A thorough treatment of the data on MeOH and water at different temps. is given. W. J. Sweeney

Observations on viscosity theories. P. C. van der Willigen. *Kolloid Z.* **46**, No. 1, 55–7(1928).—Crit. observations regarding the work and theories of K. C. Sen, N. R. Dhar and coworkers (cf. *C. A.* **20**, 1158, 3113; **21**, 1044, 3515; **22**, 2094), who consider the charge induced by adsorbed electrolyte to affect the viscosity of the colloid directly. These views are considered incorrect because (1) in the presence of large concn. of electrolyte other phenomena play a role, and (2) in the presence of small concn. of electrolyte, the assumptions are neither experimentally nor theoretically proved L. F. Marek

The effect of temperature on the viscosity of neon. R. S. Edwards. *Proc. Roy. Soc.* (London) **A119**, 578–90(1928).—The ratios of the viscosities of Ne at various temps. between —78.4° and 444.5° have been detd. by a const.-vol. method. The values for $\eta \times 10^4$ in c. g. s. units at various temps. are: —78.4°, 2.367; 15.0°, 3.076; 100.0°, 3.656; 184.4°, 4.177; 302.0°, 4.901; 444.5°, 5.584. An accuracy of 0.2% is claimed for these values. The formulas of Lennard-Jones and Sutherland are tested by these figures, neither showing any decided superiority. W. T. R.

The free path of molecules and the coefficients of internal friction in fluids. N. Gerasimov. *Physik. Z.* **29**, 575–84(1928).—A mathematical and theoretical paper. R. L. Hershey

The adsorption of hydrogen, ethylene, acetylene and ethane by stannous oxide. J. N Pearce and Sylvia M. Goergen Univ. of Iowa. *J. Phys. Chem.* **32**, 1423–33(1928).—The adsorption isotherms of H_2, C_2H_2, C_2H_4 and C_2H_6 on a hydrated SnO were detd. at 0°, 78.5°, and 100°. The adsorption of H_2 was found to be very small for all temps. That of the hydrocarbons is larger and decreases rapidly with rise in temp. The relative amts. of the gases adsorbed are shown by the following data given at 78.5° and at 75 cm. pressure: Vol. of gas adsorbed by 10 g. of the oxide, for H_2, 0.27; C_2H_2, 254, C_2H_4, 1.76; C_2H_6, 2.13. The oxide is reduced by H_2 at 183°. On the other hand C_2H_2 is polymerized as low as 100°. Hydrogenation of C_2H_4 was found at 100° when a mixt. of the 2 gases contg. a relatively large amt. of H_2 was in contact with the oxide. This indicates that the adsorption of H_2 is necessary before the reaction can take place. H. F. Johnstone

The adsorption of vapors on an amalgamated platinum surface. John Wm. Smith. Univ. College, London. *J. Chem. Soc.* **1928**, 2045–51; cf. McHaffie and Lenher, *C. A.* **19**, 3188.—The adsorption of the vapors of H_2O and C_6H_6 on an amalgamated Pt surface was measured at pressures near the satn. values and at temps. from 25° to 40°. The amalgamated surface was produced by allowing a Na amalgam to stand in the Pt vessel overnight, then washing the vessel with dry Hg and finally removing the last traces of Na with H_2O. Such a surface was quite permanent in the vapors studied but not in the lab. atm. Both vapors showed definitely the existence

of multimol. adsorbed films. The thickness of the H_2O film varied from 1 to 30 mol. and that of C_6H_6 from 1 to 150 according to the temp. and pressure. In the amalgamated vessel the vapor pressures of the liquids were always slightly lower than those under normal conditions. H. F. JOHNSTONE

Adsorption of mixtures of easily condensable gases. SIMON KLOSKY AND LEO P. L. WOO. Catholic Univ. *J. Phys. Chem.* **32**, 1387–95(1928).—Adsorption isotherms of C_4H_{10} at 0° and 25°, and of CH_3Cl at 25°, 35° and 45° on a titania gel were detd. by a dynamic method similar to that of Patrick and Opdyke (*C. A.* **19**, 2290). In the same way the adsorption of mixts. of SO_2 and CH_3Cl and SO_2 and C_4H_{10} by titania gel was measured at 25° and 35°. It was found that the equation:

$$\frac{N_0 - N}{N_0} \Big/ \frac{N_0' - N'}{N_0'} = \frac{M_2\eta_2}{M_1\eta_1}$$

shows a good agreement with the measured results. Here N and N' represent, resp., the no. of mols. of the 2 components of the gases adsorbed per g. of gel from the mixts. N_0 and N_0', the corresponding amts. adsorbed from the gas-air mixts., M_1 and M_2 the mol. wts. and η_1 and η_2 the viscosities of the gases. In other words, the relative adsorption lowering of one gas due to the pressure of the other is approx. inversely proportional to the product of the mol. wt. into the viscosity. The av. deviation is about 3%. The formula holds equally well for the results obtained by Richardson and Woodhouse for the adsorption of mixts. of CO_2 and N_2O on charcoal (cf. *C. A.* **18**, 187). H. F. JOHNSTONE

The existence of the Volmer adsorption film. FR. MOLL. I. G., Hauptlaboratorium, Ludwigshafen a. Rh. *Z. physik. Chem.* **136**, 183–5(1928); cf. *C. A.* **20**, 1935.—An improvement of Volmer's method, when applied to phthalic anhydride, coumarin and $(C_6H_5)_2CH_2$, showed the presence of adsorption films on crystals of these substances. This method gave negative results with paraffin and cetyl alc. The method is such, however, that the negative results do not prove the absence of the adsorption film. A new method involving the use of interference colors observed through a polarization microscope proved that adsorbed benzophenone and salol mols. diffuse through a glass plate. R. L. DODGE

The reversal of Traube's rule of adsorption. HARRY N. HOLMES AND J. B. McKELVEY. Oberlin College. *J. Phys. Chem.* **32**, 1522–3(1928).—Freundlich showed that C, a non-polar solid, adsorbs from aq. soln. the higher members of a homologous series of fatty acids (butyric, propionic, acetic and formic acids) more strongly than the lower members, as would be expected from Traube's rule that the higher members lower surface tension to a greater degree. It is now pointed out that the conditions should be reversed when a polar solid adsorbs the acids from soln. in a non-polar liquid and it is found exptly. that SiO_2 adsorbs the acids from soln. in toluene in the order caprylic < butyric < propionic < acetic. F. L. BROWNE

Adsorption anomalies. WOLFGANG OSTWALD. *Kolloid Z.* **43**, 268–76(1927).—From a consideration of published data it is shown that adsorption anomalies occur both for very small and very large amts. of the adsorbent. The relative adsorption decreases for small quantities of the adsorbent and has a max. value for a critical amt of solid phase. When a large excess of the adsorbent is used, the relative adsorption again falls, but later passes through a min. and begins to rise again. The behavior is explained as being due to the dispersion of some of the adsorbent, so increasing the surface; with very small quantities of adsorbent, the adsorption causes the coagulation of this dispersed material, corresponding with the fall in the relative adsorption. The anomaly in the region of large amts. of adsorbent is explained as a normal function of the curve connecting x/m with m, where x is the amt. of adsorbed material and m the amt. of adsorbent. B. C. A.

Adsorption of gases by chabasite. FRANZ SIMON. *Z. physik. Chem.* **132**, 456–9(1928).—The dehydration of chabasite which occurs on heating takes place in stages which show a stoichiometric relation between the wt. of the water and that of the dehydrated silicate. Measurements have been made of the adsorption of A and of N by the anhydrous substance at 90.2° abs. in order to det. whether similar relations obtain. The curves derived by plotting pressure against vol. of dissolved gas consist of a series of straight portions, with breaks at the points which correspond with the ratio 1 mol. gas:1 mol. chabasite. The slope of the curve at this point changes 75% for A and 85% for N. The curves exhibit breaks also at $^1/_2$ mol. of gas. The theoretical significance of these observations is discussed. B. C. A.

The adsorption of gases by graphitic carbon. II. X-ray investigation of the adsorbents. H. H. LOWRY AND R. M. BOZORTH. Bell Telephone Labs. *J. Phys.*

Chem. **32**, 1524–7(1928).—Ruff and collaborators (*C. A.* **22**, 546) concluded that graphite cannot be made to adsorb considerable quantities of gas and that only amorphous C has high adsorptive capacity. Data of Lowry and Morgan (*C. A.* **19**, 3398) show that C prepd. by the explosion of graphitic acid has $^1/_3$ to $^1/_4$ the adsorptive capacity of the best charcoal. It is shown here by x-ray investigation that this C is in fact graphitic in structure as was previously inferred by Burns and Hulett (*C. A.* **17**, 1564) from the agreement in its d. with the d. of graphite. The individual particles are found to be flakes approx. 50 atoms in diameter by 10 atoms in thickness. The method of prepn. makes it reasonable to suppose that the crystal lattices are broken up to a considerable extent, leaving the surface atoms highly unsatd. and that the lower adsorptive capacity of Ruff's graphite was due to the fact that it was merely mechanically finely divided and not made up largely of broken crystals. In other words, to have high adsorptive capacity, a material must have not only high sp. surface, but highly unsatd. atoms at the surface. F. L. Browne

Heat of adsorption on charcoal of certain organic vapors. Lloyd McKinley and J. N. Pearce. State U. of Ia. *Proc. Iowa Acad. Sci.* **34**, 216(1927).—Previous work (*C. A.* **21**, 1575) on the heat of adsorption has been carried out by the use of the ice calorimeter adapted only to liquids of appreciable vapor pressure at 0°, and affording no investigation of the effect of temp. upon the heat of adsorption. A method for studying the heat of adsorption at different temps. by employing a sensitive thermocouple in a calorimeter system consisting of a known wt. oil of low sp. heat in a Dewar flask is mentioned. With this arrangement it was found that a change of 1 microvolt in the thermocouple reading corresponds to 0.06 cal. per g. of charcoal. W. G. G.

The adsorption of certain vapors by charcoal at various temperatures up to and above their critical temperatures. J. N. Pearce and C. M. Knudson. *Proc. Iowa Acad. Sci.* **34**, 197–212(1927).—The adsorption isotherms have been detd. at several temps. for each of the vapors, EtOH, MeOH, H_2O, NH_3 and CH_3NH_2. The adsorbent was a uniform sample of a specially prepd., acid-washed, ash-free, steam-activated charcoal. The isotherms for H_2O vapor indicate that a different type of phenomenon is involved here than in the case of the other vapors. The retention of the H_2O vapor by the charcoal is probably due to mere capillary action rather than to the surface forces of adsorption. The Freundlich isotherm relation has been shown to apply, except near satn. to the 2 alcs. and to NH_3, but not to H_2O and CH_3NH_2. The Kayser equation, as used by Gaddes, is applicable only within a narrow range, while the equation of Schmidt and Hinteler, and that of Williams do not seem to apply in any range. It is found that neither the Homfray nor the Freundlich equations for the isobars express satisfactorily the relations shown by the isobars. The Freundlich isostere equation, for the special case where $\xi = 0$, applies with considerable accuracy, except at high temps. The Ramsay and Young law is not applicable to these vapors. The law of corresponding states holds approx., except for H_2O and CH_3NH_2. W. G. Gaessler

Adsorption by decolorizing earth in nonaqueous solutions. Bernhard Neumann and Salomon Kober. *Kolloidchem. Beihefte* **27**, 1–44(1928).—Decolorizing earths show greater ability to decolorize natural soy oil if they are heated to about 600° before use. This treatment lowers the adsorptive power of the material for dyes in paraffin oil. It is shown that no chem. decompn. results from the heat treatment in question so the change in adsorptive power must be caused by a change in some phys. property such as porosity. The colored matter in natural soy oil is colloidal while the dye in the paraffin-oil soln. was crystalloidal. It is shown that in general heating a decolorizing earth above the temp. necessary to remove adsorbed water increases its adsorptive ability for colloids but lowers it for crystalloids. J. G. McNally

Adsorption processes in flotation. K. Kellermann and E. Peetz. *Kolloid-Z.* **44**, 296–308(1928).—The adsorption of caprylic (octoic) acid by quartz and by galena was studied by measurements of the *n*, elec. potential, elec. cond., and surface tension. Examn. of the system quartz–octoic acid showed that, although quartz does not act as an adsorbent, a portion of it goes into colloidal soln. under the peptizing influence of octoic acid, and in this state it acts as an adsorbent. Galena is attacked by octoic acid, and the measurements were carried out in presence of a soln. satd. with respect to Pb octoate. Galena adsorbs octoic acid well, although the dried material does so poorly. The consts. of the adsorption isotherms have been calcd. from the exptl. data, and also the mol. thickness of the adsorption layers. Under the exptl. conditions, galena is readily floated, while quartz is not; the parallel between flotation and adsorption is discussed in regard to flotation practice. B. C. A.

Adsorption in mixtures of solvents. E. Angelescu and V. N. Comănescu. *Kol-*

loid-Z. **44,** 288–96(1928).—Measurements have been made of the adsorption of picric acid by animal charcoal in benzene, Et alc., and acetone and in various mixts. of the following pairs of liquids: Et alc.-chloroform, benzene-Et ether, Et alcohol-Et ether, acetone-benzene, Et alc.-benzene, acetone-chloroform, acetone-Et alc. and acetone-water. The concn. of the picric acid was varied between 2 and 8%. The results show that the ordinary adsorption equation $a = kc^{1/n}$ is applicable to mixts. of solvents. The values of the exponents vary between narrow limits, and the const. k is inversely proportional to the nth root of the soly. l of picric acid in the solvent or mixt. of solvents. The product $kl^{1/n}$ is a measure of the affinity between animal charcoal and picric acid and can be used as a measure of the adsorptive power of a specimen of charcoal. Exceptions to these generalizations were found in the mixts. of acetone with water or Et alc. contg. a high percentage of acetone. B. C. A.

Adsorption phenomena in solutions. XI. NIKOLAI SHILOV AND KONSTANTIN CHMUTOV. *Z. physik. Chem.* **133,** 188–201(1928).—C purified by ignition in air differs from that prepd. by treating with H at a high temp. in that it always retains a film of adsorbed CO_2. The hydrolysis of both weak and strong electrolytes brought about by adsorption on C has been followed by p_H measurements, and in agreement with observations of the related phenomena of cataphoresis and electro-osmosis. it is found that with a neg. adsorbent the anions are adsorbed before the cations. Two stages in the process of adsorption can thus be defined: in the first the charge on the adsorbent increases by reason of the adsorption of ions bearing charges of the same sign as that of the adsorbent; in the second ions of the opposite sign are adsorbed and this corresponds with mol. adsorption. This theory is in accordance with the observation that strong electrolytes undergo hydrolysis when in contact with an adsorbent, whereas weak electrolytes merely experience mol. adsorption. B. C. A.

Adsorption and solution phenomena encountered in precipitations. FREDERICK R. BALCAR WITH GEBHARD STEGEMAN. Pittsburgh Univ. *J. Phys. Chem.* **32,** 1411–21(1928).—When $BaSO_4$ is pptd. in solns. contg. $ThCl_4$, the Th ion is removed from the soln. in large quantities (cf. Kammer and Silvermann, *C. A.* **20,** 9). With continued agitation, however, the Th reënters the soln. The concn. of Th ions has a marked effect on the size of the $BaSO_4$ particles. The solubilities of $BaSO_4$ and of $PbSO_4$ in solns. of $ThCl_4$ are considerably larger than those in H_2O and were found to follow the Freundlich isotherm: $S = KC^n$, where C is the concn. of $ThCl_4$ and K and n are consts. The values of $-\log S/S_0$ (S_0 = the soly. in H_2O and S the soly. in the presence of $ThCl_4$), which, according to the theory of Debye and Hückel, should equal the log of the activity coeffs.. are of the order of 100 times too large. While the equil. relations between Ba^{++} and SO_4^{--} ions in solns. of $ThCl_4$ do not obey the usual mass-action law they indicate that there is a sp. interaction of the ions rather than any complex ion formation. The adsorption of Th ions by $BaSO_4$ when the latter is pptd. in a $ThCl_4$ soln. does not follow the isotherm, $x/m = KC^n$, because of the changing values of C as the sulfate is pptd. The equation: $x/m = KC^F/\sqrt[3]{m}$, where F is a logarithmic function of m, is suggested to represent the results. H. F. JOHNSTONE

Adsorption and crystal form. CHARLES H. SAYLOR. *Fifth Colloid Symposium Monograph* 1927, pp. 49–54.—NaCl crystallizes from pure water in cubes, but in the presence of urea it gives octahedra or cubes with octahedron faces truncating the cube corners. In general, if a substance crystallizable in 2 forms, is allowed to crystallize first in the presence of a presumably strongly adsorbed cation, and then again in the presence of a presumably strongly adsorbed anion, one of these solns will show increased tendency to yield the less stable crystal form. If, *e. g.*, the less stable form appears in alk. solns., one can predict that all strongly adsorbed anions will tend to produce the same effect, and that strongly adsorbed cations will tend to counteract it. Preferential adsorption on certain crystal faces changes the rate of growth of such faces. Alc., by opposing the adsorption of anions, works against the urea and anion effect, detg. formation of cubic NaCl. "This new technic is absolutely general... works as well for strongly adsorbed cations as anions....applies equally well to melts... can be used with substances belonging to any crystal system. Although in any case an adsorbed material may throw the habit either way, a single key reaction makes it possible to predict the rest. The only condition is that some substance shall be adsorbed preferentially on one of the several possible crystal habits." $SbCl_3$ in NaCl solns. gives ions of H_3SbCl_6, which are so strongly adsorbed on the octahedron face as to lead to inclusions in rapidly grown NaCl octahedra. K alum ordinarily forms octahedra, but from weakly alk. solns. (K_2CO_3, borax) it gives cubes. Methylene blue forces $BaNO_3$ to form cubes (often with colored faces); H-ions act similarly Urea and OH-ions oppose the natural tendency of $Ba(NO_3)_2$ to form cube faces on its

octahedra. $NaNO_3$ crystd. in the presence of HNO_3, the H-ions being adsorbed on the prism faces, it produces long thin crystals; and, as expected, NaOH produces short stubby crystals. An octahedron face of NaCl, when rubbed against a cube face, developed a negative charge. Other substances will, no doubt, behave the same way. When there is no change in the underlying cryst. structure, the *habit* on which adsorption occurs is favored; but when there is a change of structure, the *modification* on which adsorption occurs is repressed. Excessively strong adsorption on a cryst. modification tends to peptize it and put each cryst. nucleus as it forms into colloidal soln., removing it as a starting point for crystal growth, so that supersatn. occurs for want of seed crystals. Thus quinoline yellow causes supersatn. of K_2SO_4; acid dyes cause several hundred % supersatn. in TlCl. On slowly adding, at 60°, 0.1 *M* K_2CO_3 soln. to a soln. contg. a small amt. of $Ca(OH)_2$ and an excess of KOH, only calcite appears. On adding 0.1 *M* $CaCl_2$ to a soln. contg. 50 g. K_2CO_3 in 700 cc. water, one gets principally μ $CaCO_3$ (hexagonal, optically positive, known also as *vaterite*), with a small amt. of aragonite and a trace of calcite. As the carbonate is decreased, aragonite begins to supplant the μ $CaCO_3$, and with still smaller amts. of carbonate, calcite dominates. "I therefore postulate that the carbonate—or more probably the bicarbonate—ion is adsorbed on the calcite, less on the aragonite, and least on the μ $CaCO_3$, that it peptizes the crystal nuclei of the forms on which it is most strongly adsorbed, and prevents their appearance in recognizable crystals." Similar results follow in melts; strong adsorption on a crystal nucleus enables metastable modifications to appear. JEROME ALEXANDER

Adsorption from solution by ash-free adsorbent charcoal. ELROY J. MILLER. *Fifth Colloid Symposium Monograph* 1927, pp. 55–80; cf. *C. A.* 22, 3079.—Expts. with ash-free activated sugar charcoal show: it adsorbs acids but not the inorg. bases; strong inorg. bases are negatively adsorbed; salts are hydrolytically adsorbed, this being exclusively the case with neutral salts of inorg. acids, *e. g.*, NaCl, K_2SO_4 only acid being adsorbed and the corresponding base remaining in soln.; the adsorption of salts of highly adsorbed organic acids, *e. g.*, Na benzoate or salicylate, is partly hydrolytic and partly mol. The charcoal being free from impurities, the adsorbed acids may be quantitatively removed and identified, and is equiv. to the base set free. All other *pure* charcoals, whatever their original source, behaved similarly; but if the purified charcoals were treated with chosen impurities, the adsorption anomalies of the literature could be reproduced. It appears that the charcoal acts like the org. liquid in the Langmuir-Harkins interfacial oriented adsorption theory. Introduction of amino acids or OH groups into org. acids invariably results in a decrease in adsorption. Closer accord with the Gibbs adsorption theorem is shown by pure than by unpurified charcoals. Mol orientation seems to be involved in the adsorption. Thus, with hydroxy- and aminobenzoic acids adsorption is greatest with the *o*-compds., less with the *p*-, and least with the *m*-compds. Chloro- and dichloroacetic acids are more strongly adsorbed than AcOH, while aminoacetic acid is not adsorbed at all; this indicates that some groups favor adsorption, while others oppose it. With butyric, valeric, and caproic acids, the iso forms are less adsorbed than the normal forms. NH_4OH is not adsorbed at all NMe_4OH is very slightly adsorbed, and NEt_4OH is adsorbed as strongly as the inorg. acids. Sulfosalicylic acid is adsorbed much less than benzoic, salicylic, or aminobenzoic acids. When adsorbed on charcoal, acids are incapable of inverting sugar, indicating the non-ionization of the acid. "It seems certain that adsorbed acids exist in direct mol. contact with the surface atoms of the charcoal." "The non-dissociation of the adsorbed electrolytes is of crit. importance for theories of electrokinetic potential." The H-ion is highly adsorbed, but many facts indicate that the OH-ion shows negative adsorption, which necessitates revision of the common explanation that charcoal is negatively charged in alk. soln., for obviously, the charge cannot be due to adsorption of OH-ions. By adsorption from buffer solns. it was shown that pure charcoal has no isoelec. point, and that the isoelec. point of blood charcoal is likewise fictitious. JEROME ALEXANDER

Some unsolved problems in the molecular-kinetic behavior of colloidal suspensions. ELMER O. KRAEMER. *Fifth Colloid Symposium Monograph* 1927, pp. 81–112.—"The purpose of this paper is to survey the evidence which may indicate the limits of validity of the simple kinetic theory (dealing with Brownian motion, sedimentation, etc.), to exam. the possible causes for departure from ideal relationships, and to consider particularly the extent to which the elec. charge or the vol. of colloidal particles may modify their behavior. In developing the theory of the Brownian motion in a gravitational field, Einstein, Smoluchowski, Debye, Schrödinger and their successors assume a uniform gravity drift, unmodified by the superimposed Brownian motion for particles suspended in a medium infinitely deep. In other words, after appropriate subtraction

of the drift due to gravity from the total motion, the remaining displacements are assumed to be identical with those to be expected in the absence of gravitational influence. This simple additivity relationship was assumed to be approx. true in practical cases during the first stages of sedimentation." Many other writers, *e. g.*, Ayres, Bancroft, Bayliss, Bradford, Burton, Holmes, Truog, explain the stability and absence of sedimentation in colloidal systems by supposing that a sufficiently vigorous Brownian motion overcomes or neutralizes the tendency to settle even in an infinitely deep dispersion, thus effecting stability. Following a crit. discussion of the work of Fletcher, Eyring, Millikan, Svedberg, Nordlund, Burton, Westgren, Brillouin, Iljin, Lorenz and Eitel, Porter, Costantin, Mendenhall, Barkas, and others, K. states: "These considerations lead to the conclusion that the questions concerning the validity of the ideal kinetic equations as a description of the behavior of suspensions, remain unanswered by recent studies of sedimentation. The problem of stability of such suspensions has the same status. It has not yet been proved that the forces which prevent collision and adherence of the particles, also give rise to the more or less uniform concentration commonly observed in these systems, even when dil. If these stabilizing forces were to operate with such long ranges as to prevent sedimentation under the influence of gravity, there is every reason to believe that the same forces would likewise reveal themselves in such phenomena as Brownian motion, diffusion, spontaneous fluctuations, as well as sedimentation. Until these various phenomena yield the same conclusions concerning the non-ideality in the kinetic behavior of suspensions, isolated cases of discrepancy between observations and theory may be suspected to be due to spurious effects of an external character." JEROME ALEXANDER

Investigation of adsorption on glasses and filtering media by the method of radioactive indicators. HERTA LANG. *Weiner Anz.* **1927**, 7–8; *Physik. Ber.* **8**, 766(1928).—The adsorption of Th B, Th C and Po on filtering media, dialyzing membranes, various kinds of glass, quartz and paraffin was measured and earlier work of Paneth and Godlewski substantiated and extended. In many glasses satn. was reached when only a small fraction of the surface was covered. Hard Jena glass adsorbs much less Po than soft glasses and is therefore to be preferred. G. L. CLARK

Extension of Dulong and Petit's law to gaseous compounds and mixtures. A. PRESS. *Phil. Mag.* [7], **5**, 832–4(1928).—From former thermodynamic studies (*C. A.* **22**, 533) P. derives the relation $2\alpha = (\gamma - 1) \times S \times M$; where α = a factor, γ = ratio of sp. heats, S = sp. heat, M = mol. wt. The constancy of the factor 2α is shown for a large no. of substances. GEORGE GLOCKLER

The physical properties of heterogeneous ternary mixtures. PAUL MONDAIN-MONVAL. *Compt. rend.* **187**, 444–7(1928).—M. does not agree with Brun (cf. *C. A.* **22**, 1090) that for the system EtOH, iso-AmOH, H_2O there is disturbance in the phys. properties near the crit. point in the homogeneous region. From a study of n he finds no distortion. E. G. VANDEN BOSCHE

Some physical properties of phenol in benzene. LLOYD E. SWEARINGEN. Oklahoma Univ. *J. Phys Chem.* **32**, 1346–53(1928).—The ds., viscosities and surface tensions of several PhOH-benzene solns. and the surface tensions of satd. solns. catechol, resorcinol, hydroquinone, pyrogallol and phloroglucinol in benzene have been measured at 25°. The apparent molal vol. of PhOH in benzene was calcd. and found practically const. over the entire range of concn. studied, thus indicating the existence of only ideal solns. The viscosity-compn. and surface tension-compn. curves for PhOH-benzene solns. both exhibit minima. These indicate, resp., that PhOH mols. are associated in the more concd. solns. and that there is an adsorption of benzene in the surface layer. The surface tension of satd. solns. of the di- and trihydroxybenzenes in benzene were all practically the same, 26.8–26.9 dynes. H. F. J.

The chemistry of clouds and dusts. I and II. H. REMY. *Chem.-Ztg.* **52**, 677–9, 698–9(1928).—If SO_3 be expelled from fuming H_2SO_4 by blowing air through it, the clouds pass through H_2O just as does NH_4Cl, but if concd. H_2SO_4 be used as an absorbent the clouds disappear instantly. If, however, a wash-bottle contg. H_2O be introduced in the train of app. after the concd. H_2SO_4, renewed clouds appear. They are therefore only rendered invisible by H_2SO_4—not completely absorbed. SO_3 from a contact plant is actually absorbed by concd. H_2SO_4; quant. expts. reported confirm this statement. KOH solns. absorb SO_3 even less satisfactorily than does H_2O. Expts. proved that all cloud-forming materials are taken up by their concd. solns. better than by dil. solns. A distinction must be made between dry clouds, as in SO_3 from a contact plant, and those that are moist, as in the SO_3 expelled from fuming H_2SO_4. The diam. of particles in moist clouds is in general above the upper limit of the diam. of colloid particles, while that of particles in dry clouds is below it, thus giving rise to the name

"colloid dusts" for the dry clouds. Tables and graphs show these characteristics for SO_3 and NH_4Cl in their action on H_2O, gas-mask C, filter paper, NH_4Cl solns. and $CaCl_2$ solns. It is pointed out that vapor pressure equil. at the surface of the particle does not play an essential part in detg. the absorptivity of a cloud in a given liquid. Investigations to det. the influence of elec. charges upon the absorptive properties of clouds showed that no such charge could be detected by observing the Tyndall effect, but with suitable electrometer the charges in clouds could be measured readily. These charges could not be looked upon as the cause of the stability of clouds, nor could the matter of completeness of wetting be demonstrated as a detg. factor in absorption. The dependence of absorptive power upon the size of the particles was established experimentally; filtered clouds were absorbed better by suitable liquids than were unfiltered clouds. The low mobility of cloud particles is the only explanation for their absorptivity. This explains also why SO_3 clouds can pass through KOH solns.—the SO_3 particles may never touch the viscous soln. Solns. of gelatin of 0.0, 0.1, 0 5 and 1.0% concn. showed similar effects, their absorptive power for SO_3 being 37.4, 29.5, 22.3 and 5.1%, resp. There is a crit. region of particle size that dets. its behavior; the lower the size of the particles the more do the clouds behave like gases, and the larger the size the more do they tend to settle out. The absorption of SO_3 in boiling H_2O is explained on the same basis of particle size and ultimate contact. The crit. region of particle size in the form of cloud or mist does not necessarily correspond with that of the colloid particles in aq. and other solns., for it really comes more nearly in the region of ordinary suspensions. The behavior of cloud particles is therefore related closely to the phenomena of colloids. The state of subdivision, as well as chem. compn., must be considered as very important. W. C. EBAUGH

Unity in the theory of colloids. H. R. KRUYT. *Fifth Colloid Symposium Monograph* **1928,** 7–18.—A crit. review. From the standpoint of the kinetic theory, it is immaterial whether a particle is mono- or polymolecular. True solns. represent a condition of equil.; colloidal solns. do not. Work in K.'s lab. has shown: Lyophylic sols are polymol.; their elec. charge is of the same type as that of suspensoids; but with the latter, it is the only stability factor, whereas with lyophylic particles, hydration is equally important. The importance of H-ion concn. has been greatly exaggerated. Brailsford Robertson, Wo. Pauli, Jacques Loeb, and Jacques Duclaux, among others, "treat protein solns. as molecularly or ionically dispersed systems. Although I differ absolutely from them, I can understand very well how they came to this viewpoint." JEROME ALEXANDER

The stability of emulsions, monomolecular and polymolecular films, thickness of the water film on salt solutions, and the spreading of liquids. WM. D. HARKINS (parts with J. W. MORGAN, NORVIL BEEMAN, B. GINSBERG and B. B. FREUD). *Fifth Colloid Symposium Monograph* **1928,** 19–48.—It was not found possible to form polymol. films of palmitic acid, or of substances contg. polar groups, *e. g.*, COOH, OH, NH_2, CO, or SH, etc. Polar groups in org. substances are not essential to spreading, for benzene, hexane, pentane and octane spread on pure water; but spreading occurs when the interfacial work of adhesion between the liquids exceeds the surface work of cohesion in the liquid. The only substances thus far found which will give polymol. films on water are: di-β-naphthylamine and symmetrical di-β-triphenylethyl. By using 40% solns. of $CaCl_2$ to increase the work of adhesion, polymol. films were obtained with phenanthrene, hexachlorobenzene, sym. di-β-triphenylethylurea, triphenylmethyl cyanide, 9,10-dibromoanthracene, di-β-naphthylamine, and α-bromonaphthalene; thickness of films varied from 110 to 400 A. U. Such films are weaker than monomol. films, but usually show, like the latter, on compression at high pressures, a linear relation between the compressive force and mol. area. They are very thin, the thickest being only about 0.1 the shortest wave length of visible light. Young's modulus for steel is about 12,000; for a monomol. film of stearic acid on water, it is 39 (less if on $CaCl_2$ soln.). Polymol. films of dibromoanthracene showed less than 2. If 2 substances form monomol. films, their mixts. do likewise. Mixts. of stearic acid and phenanthrene gave polymol. films, almost all of the latter being piled up on the under monomol. layer of stearic acid. The film strength equals or surpasses that of pure acid with 1 mol. phenanthrene to 2.58 acid, but decreases if much more of the former is present. A method was developed for detn. of the stability of emulsions, by detg. the distribution of size of droplets in the freshly prepd. emulsion and at intervals later. The stability may be expressed by the distribution curves themselves, or by the change of area per unit vol. of oil. With concd. emulsions, sufficient diln. must be made to prevent changes during test, and the size distribution detd. by a photographic optical method (Stamm, *C. A*. **19,** 2768), by a density method (Kraemer and Stamm, *C. A*.

19, 761), or by direct microscopic measurement (Finkle, Draper and Hildebrand, *C. A.* **18**, 607). Concd. octane emulsions made with 0.005 *N* Na or Cs oleate are unstable when fresh, the interfacial area decreasing rapidly; with the former soap from 25,500 sq. cm. per cc. octane to 14,600 in 3 days, and from 25,000 to 13,800 with the latter soap. Evidently the concn. of soap in the monomol. film increases rapidly. After 2 days the area per mol. of soap in the film was 61 sq. A. U. with 0.005 molar soaps, and 64 sq. A. U. with 0.01 *M* solns., indicating a moderately dil. monomol. layer. This is practically 3 times the area of oleic acid in concd monomol. films on water. Concd. emulsions were obtained with extremely dil. soap solns., but below 0 008 *M* the emulsions were too unstable to measure. Without emulsifying agents, no higher than 4% of oil can be emulsified in water. "However, with soap as an emulsifying agent, a highly concd. emulsion may be obtained by the formation of a *highly dil. monomol. film.* The film will produce such an emulsion even if it contains only about $^1/_5$ or $^1/_{10}$ the no. of mols. contained in a tightly packed monomol. film of soap. Such an emulsion is not stable, and a process occurs in which the distribution of sizes changes in such a way that the mean drop-size increases. This causes a decrease in area per mol., until this area becomes about that to be expected for an ordinary tightly packed monomol. film." To obviate optical errors, an image of a thin layer of emulsion was projected on a specially prepd. screen, by using an arc, a microscope giving $\times 61$, having 3-mm. apochromatic oil immersion objective of 1 40 N. A., and a $\times 25$ compensating ocular, with an aplanic condenser of 1.40 N. A. The screen was ruled with lines about 0.7 mm. apart, corresponding to 1μ. As cell was used a special hemocytometer 0.1 mm. deep, with a very thin cover glass. Curves are given showing the distribution of droplet sizes in stanolax (a heavy paraffin oil) and octane emulsions, 4019 and 2420 droplets, resp., being measured. Na, K, and Cs oleates gave parallel results, indicating that the at. vol. of the cation is not determinative. Na stearate, elaidate, and cerotate showed like results, but the gelling of the last made accurate observation difficult. With K chaulmoograte (0.1 *M*) the no. of visible droplets between 0 and 1μ was double that between 1 and 2μ, whereas with the other anions the contrary was true. Chaulmoograte emulsions aged more in a few hrs than oleate emulsions did in a year. Water-in-oil emulsions made by dissolving Mg and Al oleates in stanolax, and then beating in water, showed counts similar to the oil-in-water emulsions. When the oil and pure water were mixed, about 10 times as many droplets of oil appeared in the water, as of water in the oil, after 2 hours' standing. Although stanolax has 400 times the viscosity of octane, the peak in the distribution curve lies about 1.5μ in each case. Benzene shows the peak at about 0.5μ, indicating that other factors than viscosity dominate Sometimes the motor-driven egg beater failed to effect emulsification speedily; but when a foam appeared, emulsion at once formed. The peak was changed but slightly by different procedures. Slight excess of NaOH or of oleic acid produced no material change; but 0.1 *M* base considerably increased the no. of smaller drops. Stability is usually lessened by addn. of 0.1 *M* oleic acid to the org. phase, or of 0.1 *M* NaOH or NaCl to the aq. phase before emulsification. Exceedingly dil. emulsions made without stabilizing agents exhibit the usual type of size distribution. A graph is given showing thickness of water films on salt solns. That on NaCl, extrapolated to zero concn is 3.8 A. U. Contrary to literature statements, NaCl is negatively adsorbed at a water-benzene interface, where, with concd. salt solns., the water film equals that between salt soln. and vapor. With dil. solns., however, the former is slightly thicker Calcns. indicate that on aq. solns. of org. solutes (*e. g.*, MeOH or EtOH), the surface film is somewhat thicker than monomol. in more concd. solns. A modified form of Donnan's app. is illustrated and described. "With CS_2 as well as other non-spreading liquids Antonow's relation, so generally cited as entirely correct, is very far from true Preliminary illustrations are given of the form of hanging and falling drops. A table is given showing the no. of regions, interfaces, and phases for a few systems of zero degrees of freedom. JEROME ALEXANDER

Colloidal platinum. IV. The existence of hexahydroxyplatinic acid in colloidal platinum solutions. STUART W. PENNYCUIK. Univ. of Adelaide, S. Australia *J. Chem. Soc.* **1928**, 2108–17; cf. *C. A.* **22**, 2305.—Colloidal Pt solns. carefully prepd. by the Bredig method contained a free acid, $H_2Pt(OH)_6$, hexahydroxyplatinic acid, after the Pt was coagulated. This acid, first prepd. by Wöhler and by Belluci, is a strong dibasic acid, more stable than chloroplatinic acid. The presence of the acid was shown by coagulating the Pt by freezing and then titrating the clear soln. Dehydrated forms of this acid, *e. g.*, $H_2PtO(OH)_4$ or $PtO_2 \cdot 2H_2O$ may be present with the acid. The hexahydroxy acid is part of the structure of the colloid particle, as shown by the fact that when the fresh sol is centrifuged, the cond. on boiling increases from about

6 to 25 gemmhos. This increase in cond. must be due to the strong acids sepd. from the colloid particle by boiling. This acid is not formed by oxidation for a max. cond. of about 39 gemmhos is reached upon boiling for 8 hrs. followed by coagulation. The same results are obtained if an atm. of N is used. The stability of the colloid may be due to the ionization of the surface acid. Coagulation of Pt sols by bases is considered with reference to neutralization of the surface acid. A. J. CURRIER

Collected reviews on colloidal technic. V. Electrical insulating materials. HANS STÄGER. *Kolloid Z.* **46**, 60–6(1928).—The dielec. strength phenomena are self-evidently associated with capillary chem. changes such as changes in degree of dispersion and in the colloidal state as well as with pure elec. processes. Aerosols bear an important part in the dielec. strength of air. Dissolved gases, dissolved or dispersed water, dispersed solids, oxidation products, etc., influence the use of oils for insulation. The prepn. of oils may include filter pressing, or centrifuging to remove colloidal matter. With solid materials the fibrous structure as well as the hydrophilic qualities must be considered. This is especially true in the manuf. of insulating paper where a wax is used for impregnating. The colloid chem. aspects of synthetic resins should be understood, as they are important insulating materials. L. F. MAREK

Cataphoresis in copper oxide sols. The application of Debye and Hückel's theory of electrolytic conduction to colloid particles. H. H. PAINE. Univ. Witwatersrand, Johannesburg, S. Africa. *Trans. Faraday Soc.* **24**, 412–29(1928).—The mobility of the particles of CuO sols and similar sols to which electrolytes have been added is measured by the transportation method. The app. used consists of an inverted U tube to the bend of which a tube is fused. A Pt electrode is placed upon each limb of the tube and the 2 limbs are inverted in 2 sep. flasks. This app. possesses several advantages over other types. Results obtained by the addn. of electrolytes, KCl, K_2SO_4 and $K_4Fe(CN)_6$, to CuO sols are: (1) The first addns. of salt reduce the velocity of the particles more than later addns. do. (2) The greater the valency of the ion carrying a charge opposite in sign to that carried by the particles, the greater the effect in reducing the velocity of the particles. (3) The decrease in mobility from the value at zero concn. is directly proportional to the square root of the concn. of the electrolyte. The similarity of the Helmholtz double layer and the Debye-Hückel "structure" of the ion is discussed. The elec. conditions are the same in the ion as in the colloid particle. The central charge on the latter, however, is much greater than with the ion and the "ionic atmosphere" does not approach as closely to the center of the system. As the charge of the electrolyte increases, the charge on the particle apparently remains unchanged and the "ionic atmosphere" contracts. Some indications are given of the effect of the size of the central particle on the diminution of mobility produced by electrolytes. A. J. CURRIER

Cataphoresis and the electrical neutralization of colloidal material. SANTE MATTSON. N. Jersey Agr. Expt. Sta. *J. Phys. Chem.* **32**, 1532–52(1928).—An ultramicroscopic observation cell for rapid detn. of cataphoresis of individual colloid particles is described. Essentially it is the cell usually employed with the slit ultramicroscope except that it is 22.3 cm. long and ends in larger chambers contg. electrodes. The optical system for illumination is that of the slit ultramicroscope. The time required for a particle to traverse the scale of the micrometer eyepiece of the microscope is noted. An observation can be made in 10 to 20 sec. The following illustrations of the application of the app. are given: (1) Elec. neutralization of clay suspensions by salts of Al. Expt. showed that it is the products of the hydrolysis of these salts ($AlCl_3$ and $Al_2(SO_4)_3$), rather than the Al, which are active and that adjustment of the p_H to about 5.2 is essential for the highest degree of efficiency. (2) Neutralization of clay suspensions by methylene blue in the presence of different electrolytes. The isoelec. ratio $\frac{\text{methylene blue}}{\text{clay}}$ was increased by anions and decreased by cations, the effect increasing with the valence. (3) Neutralization of the electronegative proteins in milk by methylene blue. The isoelec. ratio decreased as the acidity of the milk increased on aging. (4) Neutralization of colloidal materials in raw sugar and in molasses with methylene blue. There is a proportionality between the neutralizing power and the quantity of colloidal material present. (5) The electrokinetic behavior of $BaSO_4$. This material is by itself electropositive in the presence of excess Ba, electronegative in the presence of excess SO_4^{--}. The electropositive condition causes a decrease and the electronegative condition an increase in the p_H. The former phenomenon is explained on the basis of difference in soln. tension of Ba and SO_4 and the latter on differential adsorption of the H and OH of H_2O. (6) The formation of a turbid suspension before dissolving of $Na_4Fe(CN)_6$. The crystal chips which in H_2O

break away from the larger crystals carry an extraordinarily high electronegative charge. The great soln. tension of the highly hydrated Na and the low tension of the quadrivalent anion are held responsible for the behavior. In conclusion it is pointed out that all electrolytes may give rise in H_2O to a dissocn. potential difference at the phase boundaries, the sign of charge being detd. by the soln. tension and osmotic pressure of the resp. ions. But the cause of the electronegative charge of the great no. of inert materials is to be sought in the adsorbed layer of oriented H_2O mols. which apparently attract the anions to the interfacial side of this layer, giving rise to an adsorption potential. Adsorbed H_2O is held to be more acidic than free H_2O.
F. L. Browne

Copper hydrosols of low electrical conductivity. G. T. R. Evans. Univ. Witwatersrand, Johannesburg, S. Africa. *Trans. Faraday Soc.* **24**, 409–12(1928).—The cond. of colloidal Cu solns. prepd. by the Bredig arc method is given for ranges lower than those recorded in previous papers. The values vary from 0.30 mho./cc. to 0.57 mho./cc. The cond. water used was prepd. with utmost care. In every case the cond. of the water is greater than that of the Cu sol. This may be due to adsorption of the impurities by the Cu sol or to some action by which ions are removed from soln. The sols are very stable but after storage for several months the cond. increased. This effect is not explained. A. J. Currier

"Solid-phase" rule in the production of coarsely disperse systems. Wolfgang Ostwald, Walter Steinbach and Rudolf Kohler. *Kolloid-Z.* **43**, 227–32(1927).—The rule that in the direct dispersion of a substance to form a colloidal system the amt. of substance peptized at first increases, passes through a max., and subsequently decreases with the amt. of the solid phase present also holds for the production of coarsely disperse suspensions and emulsions. Results in accordance with the rule were obtained in the emulsification of olive oil and water (with or without the addn. of an emulsifier) and in the stabilization of suspensions of charcoal by picric acid, aniline and pyridine. It is shown that picric acid not only has a stabilizing effect on a suspension of charcoal but also causes partial dispersion. B. C. A.

"Solid-phase" rule. Wolfgang Ostwald. *Kolloid-Z.* **43**, 249–67(1927).—An attempt is made to classify the various types of peptization under the following headings: adsorption-peptization (*e. g*, C in picric acid), dissoln.-peptization (metal hydroxides in acids), peptization of swelling substances (gelatin), spontaneous colloidal dissoln. (colloidal dyes), peptization with chem reaction (formation of basic Bi nitrate sol by hydrolysis of the neutral salt). The "solid-phase" rule, according to which the amt. of peptized colloid is not independent of the amt. of solid phase present, can be explained by the principles of adsorption. If the amt. of solid phase is small, adsorption is great and the substance tends to be pptd.; on the other hand, with a large excess of solid phase adsorption is so small that little colloid-chem. effect is produced. Consequently, peptization is greatest for medium amts. of the solid phase. This view explains why the solid-phase rule applies also to the production of coarse suspensions and emulsions.
B. C. A.

The influence of lyophile colloids on the precipitation of salts—agar-agar and lead iodide. Thomas Robert Bolam. Univ. of Edinburgh. *Trans. Faraday Soc.* 24, 463–70(1928).—Cond. measurements on the solns. agar, Pb nitrate, KI, agar-KNO_3, Pb nitrate-KI showed that agar keeps Pb iodide in supersatd. soln. and prevents the pptn. of PbI_2. The PbI_2 is not in colloidal suspension since there is no color change as would be expected for a PbI_2 sol. The cond. of a mixt. of agar and salt is always less than the sum of the sep. conductivities. With Pb salts this is due to the formation of Pb sulfate, the H_2SO_4 being derived from the agar. Arthur Fleischer

Studies on the reason for a rubber-like condition of matter. P. P. von Veimarn. *Kolloid-Z.* **46**, No. 1, 38–40(1928).—Silk fibers swollen in NaI soln. and then coagulated in sodium citrate soln., exhibit considerable elasticity, which is improved by moderate mastication and destroyed by excessive mastication. An analogy is drawn to the behavior of rubber. Ultramicroscopic examn. of swollen silk fibers during elastic period shows a definite spiral structure which is lost by excessive mastication or swelling. The deduction is drawn that for elastic properties to exist a structure of spiral fibers in an amorphous matrix must be had. L. F. Marek

Preparation of negatively charged sols by means of tartaric acid. I. Properties of compounds of oxides of tin and titanium with tartaric acid. A. V. Dumanski and A. G. Kniga. *Kolloid-Z.* **44**, 273–7(1928); cf. *C. A.* **22**, 4028.—Measurements have been made of the d., viscosity, optical activity and elec. cond. of solns. of tartaric acid contg. progressively increasing quantities of $Sn(OH)_4$ and $Ti(OH)_4$, resp. The hydroxides were used in a freshly pptd. condition by adding NaOH to the tetrachlorides of the

metals. The results indicate that the reaction between tartaric acid and $Sn(OH)_4$ or Ti hydroxide can be sepd. into 2 stages: in the first stage, both the optical activity and the ionic concn. increase, and in the second stage the optical activity continues to increase while the ionic concn. remains constant. The d. and viscosity of the solns. increase linearly throughout. It is considered that the second stage denotes a colloid-chem. process, in which the excess of metallic hydroxide is peptized by the tartaric acid. Such solns. exhibit the Tyndall effect. The colloid particles migrate to the anode under a p. d. The formation of colloid can be observed when the ratio of tartaric acid to stannic oxide reaches 5:1. In the coagulation of SnO_2 sol by Na, Ba or Al chloride Schultze's rule is not followed quantitatively. B. C. A.

Charge and particle size. R. Keller. *Kolloid-Z.* **44**, 324–6(1928).—The colloidal state of matter is characterized not only by the size of the particles of the disperse phase, but also by a minimal and maximal electrostatic charge with respect to the dispersion medium. The part played by the ions in the charging of a colloid is small, especially in regard to the ions of strong acids and bases. An analogy is drawn between the elec. relations of colloid particles and mols., and it is considered that in both cases the surface charge shows itself in an elec. field through selective adsorption at one of the electrodes. B. C. A.

Distribution of particle size in reversible polydispersed systems. N. von Raschevsky and E. von Raschevsky. *Z. Physik* **46**, 300–4(1927).—By applying Planck's theory of dil. solns. to a polydispersed system considered as a mixt. of monodispersed systems, the characteristic function and distribution function have been detd. B. C. A.

Kinetic investigation of the peptization of aluminum hydroxide. Wolfgang Ostwald and Herbert Schmidt. *Kolloid-Z.* **43**, 276–95(1927).—The course of the peptization of $Al(OH)_3$ gel prepd. from NH_4 alum was followed by gravimetric and potentiometric methods. The general character of the peptization-time curves resembles that of a coagulation-time curve, being autocatalytic, or S-shaped. No relation could be found between peptization and H-ion concn., the effect depending rather on the anion of an acid. Buffer solns. of the same H-ion concn., but contg. different amts. of neutral salt behave quite differently. Many strong acids, such as H_2SO_4 and H_3PO_4, do not peptize $Al(OH)_3$. B. C. A.

Kinetic studies on the formation of starch paste. I. Formation of starch paste in the cold. Wolfgang Ostwald and Gerhard Frenkel. *Kolloid-Z.* **43**, 296–312(1927).—A study has been made of the formation of paste from starch suspensions under the influence of various added substances, and of the effect of varying the concn., temp., moisture and previous treatment. The substances which facilitate the change are Na, K and NH_4 thiocyanates, NaOH and KOH, HCl, Na salicylate and carbamide. The viscosity curve of the process is S-shaped, like that of the setting of plaster of Paris. The exptl. curves can be divided into 3 groups, according to the portion of the S-shaped curve which can be realized. The addn. agent becomes effective at a certain critical concn. and has a large "concn. coeff." The concn. of the starch suspension and the temp. are also of great influence on the velocity of formation of paste. Different velocities were found for different kinds of starch, and thus this effect can serve as a means for the characterization of starch. B. C. A.

The condition of the micelles in starch. G. Malfitano and M. Catoire. Paris. *Kolloid-Z.* **46**, 3–11(1928).—A general theory of colloids is advanced; starch is used as illustrative material for explaining it. The theory is based on 4 postulates: (1) The micelles which characterize the colloid state are complexes of a high order, that is, the units out of which they are built are neither atoms nor mols. but "mols. composed of mols." These structural units may be thought of as complexes in Werner's sense, as "polymers of polymers," or as crystals made up of micro-crystals. (2) The structural units of colloids have a dual nature, uniting electrolytes on the one hand with nonelectrolytes on the other. The duality is usually an essential condition for the colloid state, although electrolyte-free colloids can sometimes be extd. from electrolyte-contg. colloids to which this rule no longer applies. (3) In building a micelle with nonelectrolytic mols., the nucleus must be an electrolyte ion, that is, a complex in Werner's sense must be formed. It is theoretically very improbable that nonelectrolytic mols. form groups with electrolyte ions at the surface only in view of the fact that the ions are present from the beginning and play a part in the aggregation. Expt. proves that the ions are characteristic of the colloid and can neither be removed nor substituted without tearing down the micelle. Adsorption of ions may occur in addition, but it does not suffice to explain the facts. (4) The dependence of ionization and consequent dispersion upon the nature and valence of ions of charge opposite to that of the micellar

ion is the generally recognized principle for explaining stability, coagulation, sedimentation and gelation. With the true colloids this dependence expresses itself in deep-seated and irreversible changes in the condition of the micelle, especially if the ions are multivalent. F. L. BROWNE

Phenomena of dyeing colloidal grains. A. BOUTARIC AND F. BANÈS. *Compt. rend.* **187,** 117–9(1928).—Other coloring materials behave similarly to eosin in not becoming fixed on colloidal granules in the sol state (cf. *C. A.* **22,** 2698). The colloidal flocculating agents behave as dead cells and fix all the colors, the adsorption in the case of the vital colors being stronger than that exercized by the granules in the sol state L. D. R.

Theory of peptization. II. A. VON BUZAGH. *Kolloid-Z.* **43,** 215–20(1927); cf. *C. A.* **22,** 1078.—Variations in the concn. of the colloidal soln. with the proportion of solid phase are found in the peptization of palmitic acid by alkali hydroxides and of S gels. The time must be regarded as a variable in peptization processes, since there may be either aging of the sol or a slow change in the compn. and state of the solid phase. In the peptization of $Fe(OH)_3$ gel the concn. of the sol decreases with time if a large amt. of the solid phase is present. The compn. of the latter may change also because of hydrolytic processes. **III. Peptization by means of hydrophilic sols.** *Ibid* 220–4.—When sols are used as peptizing agents the curve connecting quantity of colloid dissolved and amt. of solid taken exhibits a max. as in the case of peptization by electrolytes. The systems investigated were the peptization of charcoal and of $Fe(OH)_3$ by various soap solns., of kaolin by humic acid, and of $Al(OH)_3$ by alk. alizarin solns. B C. A.

Solubility, swelling and adsorption of cellulose in alkali. W. VON NEUENSTEIN *Kolloid.-Z.* **43,** 241–9(1927).—The amt. of cellulose dissolved in alkali depends on the amt. of cellulose taken (cf. v. Buzagh, preceding abstr.), and it is probable that both adsorption and peptization processes take place. The degree of swelling of cellulose in water and alkali is similarly affected, and it is suggested that the content of electrolytes or of decompn. products in the cellulose may have an influence on the swelling. B. C A

Coagulation of colloids by electrolytes. A. I. RABINOVICH AND R. BURSTEIN *Papers pure appl. Chem. Karpow Inst., Moscow* **1927,** *Festschrift Bach* 35–53; *Chem Zentr.* **1927,** II, 1007; cf. *C. A.* **21,** 683, 2411.—*Mastic* emulsions were prepd. by (*a*) pouring water into an alc. mastic soln. and filtering, and (*b*) pouring the alc. mastic soln. into water and filtering. The *b*-sol. leaves a larger residue on filtration. Accurate conductometric titration is impossible with the *b*-sol while the *a*-sol gives concordant results. Potentiometric titrations showed that both sols are weak acids The H-ion concn. detd. conductometrically is greater with the *b*-sol then when detd potentiometrically. With the *a*-sol both methods give the same value. The *b*-sol consists of larger particles than the *a*-sol. The fact that the *b*-sol is too weak an acid for conductometric detn. is ascribed to the retention of the stronger acids with the larger particles on the filter. Upon coagulation of the sols with neutral salts no acidity develops, in contrast with As_2S_3 sols. Upon coagulation with $La(NO_3)_3$ the cation is carried down with the ppt. in a quantity equiv. to H ion present in the sol as detd potentiometrically. The equiv. quantity is insufficient to cause rapid coagulation. The coagulation value for ions with a valence of 3 and 4 is about 5–10 times the H ion equiv. In conformity with the Hardy-Schulze law it is still higher for uni- and bivalent ions. J. S. REICHERT

The coagulation of colloids with electrolytes. II. Conductivity study of the processes of coagulation of arsenic trisulfide sols. ADOLPH I. RABINOVICH AND V. A. DORFMAN. Karpov-Inst. of Chem., Moscow. *Z. physik. Chem.* **131,** 313-37(1928). cf. *C. A.* **1,** 683.—Successive addns. of solns. of electrolytes to As_2S_3 sol first increase the cond. very rapidly, then more slowly and finally the increase is linear. The rapid rise of the cond. at the start of the titration is due to the removal of the H ions by the cations of the added electrolyte. The beginning of the linear portion of the cond curve denotes the end of this H-ion-removal process, and coincides with the min. in the titration curve with caustic. The acidity calcd. from the cond. curve agrees with that found by an indirect method, but does not agree with values detd. by potentiometric measurements with a quinhydrone electrode. Upon diln. of the sol, the position of the turning pt. in the cond. curve is directly proportional to the sol concn. and inversely proportional to the concn. of the electrolyte. As the concn. of the sol increases, the difference between the coagulating value of cations of different valence decreases. The Schulze-Hardy rule is valid only for the coagulation and not for the position of the turning points in the curves, which indicates only the end of the H-ion removal

by the adsorbed ions. The difference between these two processes is strongly differentiated. The adsorption of cations of different valence reaches its max. at approx. equal equiv. concns. but the amts. adsorbed seem to be different. The dependence of the K_w of the cations of different valence upon the diln. of the As_2S_3 sols seems to be against the assumption that the coagulation can be explained by assuming that the soly. product is exceeded by the added stabilizing ion. J. H. PERRY

Coagulation of colloids by electrolytes. III. Potentiometric titration of the coagulation of ferric hydroxide sols. A. I. RABINOVICH AND V. A. KARGIN. *Z. physik. Chem.* **133**, 203–32(1928); cf. *C. A.* **21**, 683, 2411.—The chem. changes which occur during the coagulation of $Fe(OH)_3$ sols by electrolytes have been followed by potentiometric titration. The replacement of Cl ions by ions from the colloidal particles and the adsorption of ions by the latter may be thus investigated. It is found that the adsorption and the replacement of Cl ions do not take place according to the usual adsorption isotherms, but partake more of the nature of a chem. reaction. Coagulation usually occurs only after the whole of the Cl has been replaced by the anions, and in those cases in which it takes place previously, the replacement takes place from the ppt. During the titration the Cl ions are replaced by more than the equiv. quantity of other anions, the effect being greater the higher the concn. of the sol and of the coagulating electrolyte. Since there is no corresponding replacement of cations, the pos charge on the colloidal particles must be increased by the addn. of electrolyte to the sol. This conclusion has been verified by cataphoretic measurements. B. C. A.

Effect of nonelectrolytes on the stability of colloids. I. Arsenious sulfide sol. SUBODH G. CHAUDHURY. Univ. Calcutta. *J. Phys. Chem.* **32**, 1481–7(1928).—MeOH sensitizes As_2S_3 hydrosol toward $BaCl_2$ while EtOH stabilizes it. There is no parallelism between the influence of the alcs. on coagulation and their influence on the adsorption of Ba^{++}. Both MeOH and EtOH sensitize As_2S_3 sol toward HCl and reduce the velocity of cataphoretic migration. The potential of the As_2S_3 particles near the coagulating concn., detd. by cataphoresis, is higher in the case of uni-univalent electrolytes (HCl and KCl) than it is in the case of bi-univalent electrolytes ($BaCl_2$). It is suggested that the interfacial tension between particles and dispersion medium is greater in the former than in the latter case because of the higher electrolyte concn. and as a result there is greater tendency for the particles to coalesce. The conclusions are drawn that nonelectrolytes affect the coagulating power of electrolytes for colloids by (1) decreasing the dielec. const. so that coagulation takes place at a higher particle charge (sensitization) and (2) altering the interfacial tension, which also affects the potential at which coagulation takes place. F. L. BROWNE

Salting out of gelatin into two liquid layers with sodium chloride and other salts. J. W. MCBAIN AND F. KELLOGG. Stanford Univ. *J. Gen. Physiol.* **12**, 1–15(1928).—The conditions under which gelatin may be salted out into 2 liquid layers at 35° were investigated. With NaCl the equil. governing the amts. and compn. of the layers accord with the requirements of the phase rule for the quarternary system, gelatin NaCl-H ion-water. Soaps and gelatin are remarkably similar in behavior. If anisotropic regions corresponding to neat soap and middle soap are possible for gelatin, they must occur in regions where the gelatin concn. is greater than 40%. The term coagulation as applied to the salting out of proteins is a misnomer. C. H. R.

The relation between coagulation, electrokinetic migration velocity, ionic hydration and chemical influences. An experimental study of clay, quartz and permutite suspensions. PAULI TUORILA. *Kolloidchem. Beihefte* **27**, 44–188(1928).—The velocity of electroëndosmosis of water against glass surfaces was lowered by electrolytes according to the following series of cations: LiCl < NaCl < KCl = KNO_3 < $AgNO_3$ = CsCl < HNO_3 < HCl. The velocity of cataphoresis of the particles of a paraffin sol was lowered by the same electrolytes in the same order except that CsCl < $AgNO_3$, and in the case of clay particles, $AgNO_3$ > CsCl. In all concns. the order of Li, Na, K, Cs and H remained the same, but the migration velocity-concn. curve for $AgNO_3$ cut the curves for KCl and CsCl. The velocity of coagulation of these suspensions was speeded up by these electrolytes in the same order as the cataphoresis velocity was decreased except that the place of H in the series was dependent on the concn. of electrolyte used. The relation between migration velocity and time of coagulation could be expressed by an equation. With bivalent cations, the migration velocity of these suspensions was decreased in the order $MgCl_2$ < $CaCl_2$ < $SrCl_2$ < $BaCl_2$ and the decrease in the time required for coagulation followed the same order. Results are also presented for the effect of salts with acids and with bases, the velocity of coagulation still being related to migration velocity. The coagulation of mixts. of sols having particles of the same and opposite charge was also investigated. J. G. MCNALLY

Coagulation of sols with organic substances and salts. I. BR. JIRGENSONS *Biochem. Z.* **195**, 134–41(1928).—The coagulation of casein and albumin sols proceeds more rapidly when the combined action of org. substances and salts is made use of than when either alone is employed. When, however, the coagulation is made with large concns. (30–50% alc. or 0.2–1.2 *M* salt per l.) there is a slowing up of the coagulation in the case of org. substances with a low dielec. const. and the stabilization is greater the larger the concn. of the org. substance and salt. S. MORGULIS

Coagulation by uranyl salts. A. PIL. *Natuurw. Tijdschrift* **7**, 17–8(1925).—A 5% gelatin soln. with KBr coagulates on addn. of uranyl nitrate or chloride. KBr can be replaced by NaCl, KI or $BaCl_2$; the uranyl salts by themselves do not cause coagulation. Only traces of halide are necessary for the effect. B. J. C. V. D. H.

Coagulations. GEORG WIEGNER. Eidgen. Techn. Hochschule, Zurich. *Z. Pflanzenernähr. Düngung. B.* **11A**, 185–228(1928).—If the elec. discharge of particles is considered responsible for the coagulation of colloidal suspensions, then 2 types of coagulation must be differentiated. The coagulation is rapid if the elec. discharge of the particles is complete. It is slow if the particles are only incompletely discharged under a definite crit. elec. potential. If after complete or only partial elec. discharge of the particles, the contact of the particles due to the Brownian movement occurs with the same degree of probability in all directions of the vol., then, the term to be applied to the coagulation is a "rapid or slow *perikinetic* coagulation." If the probability of the contact of the particles is greater in one direction than in another, as is the case in the one-sided movement of larger particles among small particles as a result of an outer force such as gravity or centrifugal force, then the coagulation is called "rapid or slow *orthokinetic* coagulation." The slow or rapid perikinetic coagulation can occur in mono- or polydispersed systems; on the other hand, the orthokinetic coagulation due to its nature can only occur in polydispersed systems. It is necessary in the study of soil colloids sharply to differentiate: (*a*) rapid perikinetic coagulation of monodispersed systems, (*b*) slow perikinetic coagulation of monodispersed systems, (*c*) rapid perikinetic coagulation of polydispersed systems, (*d*) slow perikinetic coagulation of polydispersed systems, (*e*) rapid orthokinetic coagulation of polydispersed systems, (*f*) slow orthokinetic coagulation of polydispersed systems. From expts. on monodispersed gold sols of amicroscopic to almost microscopic size using the ultramicroscopic counting method, it was found that the law of M. v. Smoluchowski is applicable for the rapid perikinetic coagulation of monodispersed systems. Kaolin dispersions also obeyed this law. The slow perikinetic coagulation of monodispersed systems was investigated by the ultramicroscopic counting method. From the laws of M. v. Smoluchowski, the no. of active contacts of the ultramicrons at incomplete discharge can be calcd. It is correlated in definite cases with the hydration of the ions. H. Mueller has calcd. the rapid perikinetic coagulation of polydispersed systems and the formulas have been substantiated by G. Wiegner and P. Tuorila on gold sols. They are also applicable for clay dispersions. Polydispersed systems coagulated much more rapidly than monodispersed systems with the same no. of particles at the beginning of the coagulation. The difference between mono- and poly-dispersed systems having the same no. of particles is noticeable in a poly-dispersed system first when the difference between the radii of the particles in the polydispersed system is of the order 1:10. The masses of the particles are then in the same system 1000 times differentiated. The influence of the difference of the particles on the course of the perikinetic coagulation of polydispersed systems is then small, which is of significance in geology and soil science. The laws of the rapid and slow orthokinetic coagulation have been developed by P. Tuorila. Formulas were developed which apply under definite, exactly controlled conditions for the case when, after the elec. discharge of the particles, some groups of large particles fall through another group of smaller particles. The effect of orthokinetic coagulation is often of as much importance as the perikinetic coagulation in the crit. examn. of sedimentation—in suspensions—as in the mech. analysis of the soil. P. Tuorila has changed the sedimentation app. of Wiegner so that these orthokinetic coagulations may be observed in 2 different heights of the original dispersion. R. M. BARNETTE

Sol-gel systems with anisotropic particles. I. Dibenzoylcystine. H. ZOCHER AND HANS W. ALBU. Kaiser-Wilh. Inst. für physik. Chem. u. Elektrochem. *Kolloid-Z.* **46**, 27–33(1928).—Dibenzoylcystine jellies were observed under the microscope. Strong double refraction when the jellies are deformed indicates that they are built up of colloid particles that are positively birefringent needles whose diam. is far beyond the resolving power of the microscope. Only after long aging do the particles become large enough to be seen. A weak double refraction in the unstressed jellies indicates

that they are composed of spheres which in turn consist of aggregates of little needles arranged radially. On evapg. a gel to dryness a resinous film is obtained in which the needle-shaped crystals are arranged radially. The film is negatively birefringent like the crystals of pure dibenzoylcystine obtained in alc. On moistening the film with H_2O or dil. salt solns. the double refraction changes to positive. This points to the existence of a hydrate in the jellies. Observation in the polarization microscope with dark field of jellies in EtOH reveals needles as well as crystals that cannot be resolved. On aging the needles form threads. Jellies in alcs. of higher mol. wt. exhibit threads at once. At suitable concn. sols were obtained that appear streaked by reflected light and in the polariscope show positive double refraction while flowing. The nature and amt. of dispersion medium influence the double refraction. Dichroism results when the systems are colored with methylene blue or neutral red. **II. Barium malonate.** *Ibid* 33–6.—Study was made of the influence of different conditions of prepn. on the streaked aspect of Ba malonate jellies. In anhyd. glycerol the jellies are clear like water, but the streaked jellies made in com. glycerol are turbid, the turbidity increasing with increasing content of H_2O. All of the jellies are thixotropic, the H_2O-free ones especially. Jellies made in MeOH without any glycerol are stable for a long time if they are kept out of contact with air. Addn. of H_2O produces markedly streaked sols with powerful double refraction when flowing. These jellies, like those of $Mn_3(AsO_4)_2$, have normal optical properties. F. L. BROWNE

Influence of slightly soluble substances on the thixotropy of ferric oxide sols. H. FREUNDLICH AND K. SOELLNER. *Kolloid-Z.* **44,** 309–13(1928).—The accelerating influence of metals on the thixotropic change of Fe_2O_3 sols contg. NaCl is explained in the following way. Direct measurements have shown that the time of setting increases with increasing H-ion concn., and it is considered that the metals dissolve in the weakly acid Fe_2O_3 sol contg. $FeCl_3$ to a sufficient extent to diminish the H-ion concn., and thus the time of setting. The ions of the metal are without influence. Pure Au and Pt are not sufficiently sol. in the acid soln. to produce any effect. These results are confirmed by semi-quant. expts. in which a large no. of sparingly sol. substances (elements, oxides, sulfides, silicates, etc) were added. A marked difference was found between the effects produced by a sol. and an insol. steel. Substances such as graphite and S were without influence, but a pos. effect was produced by oxides of Fe. In agreement with theory, a metal is effective when sepd. from the sol by a collodion membrane. B. C. A.

Dependence of the viscosity of gelatin solutions on temperature. A. FODOR AND KURT MAYER. *Kolloid-Z.* **44,** 314–5(1928).—By means of the Ostwald viscosimeter, measurements were made of the viscosity of gelatin solns. with and without addn. of acid or alkali between the temps. 22° and 26°. The viscosity of an aq. soln. of gelatin has a higher temp. coeff. than that of a gelatin soln. contg. acid or alkali. It is inferred that solvation of the particles is not the primary cause of the increase in viscosity, and that the important feature is the formation of an adsorption compd. between the gelatin and acid or alkali. B. C. A.

Turbidity phenomena in gelatin. KURT MAYER. *Kolloid-Z.* **44,** 315–9(1928).—The turbidity of solns. of electrodialyzed gelatin was measured in an "extinctiometer" at various temps. between 12.5° and 27.5°. For each temp. a max. occurs at 1.8% of gelatin, and the turbidity is less at higher temps. The fall in turbidity with rising temp is greatest for a 1% soln. Examn. of the effect of H-ion concn. on the turbidity shows that two maxima occur, at p_H 5.2–5.4 and p_H 4.0–4.2. It is possible to purify gelatin by electrodialysis without previous dialysis by working with a small current d. and membranes with large pores, and maintaining a rapid flow of water in the anode and cathode chambers in order to remove the electrolytes. B. C. A.

The lyotropic properties of the nitrite ion. D. DEUTSCH AND S. LOEBMANN. Kaiser Wilh Inst. für physik. Chem. u. Elektrochem. *Kolloid-Z.* **46,** 22–3(1928).—The investigation was made because many pharmacol. properties of nitrites are explained upon the basis of the position of NO_2^- in the lyotropic series. The molar elevation of the surface tension of H_2O is found to be 1.2 dynes/cm., a value much less than that for $NaNO_3$, NaCl or NaF. The coagulating power of KNO_2 for Fe_2O_3 hydrosol is slightly greater than that of KCNS and much greater than that of KCl and of KNO_3. The order in which the ions influence the partition of the red form of rhodamine O between C_6H_6 and H_2O in the direction of increased concn. in C_6H_6 is $Cl^- < NO_3^- < I^- < SCN^- < NO_2^-$. The position of NO_2 in the Hofmeister series near I^- and SCN^- indicates that it is weakly hydrated. F. L. BROWNE

The influence of hydrogen-ion concentration and electrolytes upon the turbidity, sensitivity and settling rates of certain Pleistocene clays. HOYT C. GRAHAM AND J. N.

PEARCE. State U. of Ia. *Proc. Iowa Acad. Sci.* **34,** 217-8(1927).—The relative turbidities of the permanent colloidal suspensions from the different strata have been measured by means of a specially constructed tyndallmeter. The amt. of clay which can be held in H_2O suspension depends upon the stratum from which the clay was obtained, upon the H-ion concn., and upon the concn. of the electrolyte present in the suspension. Insofar as the work has proceeded, it was found that the turbidity attainable is greater for the oxidized and leached strata than for the gumbotil; furthermore, for any one stratum, the max. permanent turbidity is greater in the Kansan than in the Nebraskan. The relative turbidity increases with increasing p_H value until a certain max. turbidity is reached, and then it decreases rapidly with further increase in p_H. Except in the Nebraskan gumbotil, the max. turbidity for each clay is found at almost identically the same p_H, *viz.*, 10.5. W. G. GAESSLER

Liesegang rings and periodic precipitation. ERNEST S. HEDGES. *Chemistry and Industry* **47,** 710-2(1928).—The phenomenon may involve some fundamental principle and also interests biologists and geologists and has a literature of between 200 and 300 papers. The supersatn. theory of Wilh. Ostwald states that 2 reactants diffuse into one another and with $AgNO_3$ and $K_2Cr_2O_7$ a supersatd. soln. of $Ag_2Cr_2O_7$ is formed, the pptn. of which is delayed. By the time the ppt. has formed at the boundary of the reacting substances the gel near the ppt. is impoverished of $K_2Cr_2O_7$. Thus the advancing $AgNO_3$ has to travel some distance before it can again make the supersolv product with the $K_2Cr_2O_7$ ions and this accounts for spaces between the bands. S. L. B. ETHERTON

Organic rhythmic structures. M. COPISAROW. *Kolloid-Z.* **44,** 319-23(1928).—Rhythmic ppts. were obtained in the diffusion of picric acid, tannic acid, lactic acid, phenol, phosphoric acid and α-trinitrotoluene into gelatin. At low concns. of the colloid, striated structures without definite ring formation were produced, the rings becoming definite at a certain higher concn. of colloid. The value of this concn. depends on the quality of the gelatin. The best qualities of gelatin, or those contg. the smallest quantities of hydrolysis products, tend to form honeycomb structures, rather than stratified ppts. The expts. with tannic acid indicated a tendency towards the formation of spirals in place of rings. Rhythmic ppts. were not produced in the diffusion of pyridine, benzaldehyde, oil of wintergreen, gallic acid, and *o*-nitrophenol into gelatin, isinglass and agar. B. C. A.

A physical factor in the Liesegang phenomenon. SATYENDRA RÂY. *Kolloid Z.* **44,** 277-9(1928).—An expression is derived which gives the relation between the d and the height of a colloidal suspension. According to this there are 3 possible height for certain ds. This is considered to be the primary cause of the periodicity in Liesegang rings. B. C. A.

Ultrafiltration. STANISLAW SIERAKOWSKI. *Med. Doswiadczalna i Spoleczna* **8,** 419-34(1928).—A description of methods. JAROSLAV KUČERA

The precipitation rule in the formation of oil emulsions. RUDOLF KÖHLER. *Kolloid-Z.* **45,** 345-8(1928).—In the emulsification of olive oil and of peanut oil contg. oleic acid with dil. Na_2CO_3 or NaOH solns. the amt. emulsified at const. alk. concn. and proportion of H_2O depends upon the amt. of oil. At low concns. of alkali and of free fatty acid in the oil the amt. emulsified is max. at an intermediate proportion of oil. Increasing the concn. of alkali increases the amt. of oil emulsified. The observations are explained by application of Ostwald's pptn. rule for adsorption peptization. F. L. BROWNE

Viscosity and hydration. IV. Fluids separated by syneresis and the theory of syneresis. S. LIPATOV. *Biochem. Z.* **192,** 91-104(1928); *J. Russ. Phys.-Chem. Soc.* **60,** 467-83; cf. *C. A.* **22,** 1081.—The solns. formed from dried gelatin, agar or geranin vary with the conditions of temp., medium and content of electrolytes. When a soln. of geranin at 50° is cooled to 18°, a sol or gel is obtained according to the concn. Such a system consists of a satd. soln. in the mol. or ionic form and hydrated colloidal particles. Phase sepn. does not coincide with gelatinization, but is present already in sol and gel. Such sepn. increases gradually and leads to syneresis. The concd. colloidal phase may contain a larger amt. of water than the dilute phase and the latter may not exist at all, the whole of the water being necessary for hydration. During gelatinization, the particles which sep. from the satd. soln. gradually coalesce and ppt. as hydrated complexes, the velocity of the process depending on the distance between the particles, being greater the greater the gel concn. A 0.4% gel shows syneresis after 30 days and a 0.8% gel after 2 days. B. C. A.

Relations of the solid phase in the swelling and dissolution of gelatin. WOLFGANG OSTWALD AND RUDOLF KÖHLER. *Kolloid-Z.* **43,** 233-40(1927).—The swelling of

gelatin is influenced by the ratio of the solid phase to the vol. of liquid, the relative swelling falling as this ratio increases. The numerical values obtained by Küntzel (*C. A.* **21,** 3059) for the swelling of gelatin in HCl are plotted and lead to a quant. statement of this relation. This takes the form $q/m = kv^n$, where q is the degree of swelling, m the amt. of gelatin, v the relative amt. of liquid, and k and n are consts. It is shown that these results, are not due to the liquid being impoverished of H ions through the presence of large amts. of the solid phase. Also, similar effects were observed with 3 different types of gelatin in pure water. The spontaneous soln. of gelatin in pure water increases with increasing amt of the solid phase. It is possible to obtain in this way at 20° a weakly viscous, non-gelatinizing soln. contg. 2.5%. The influence of the amt. of the solid phase on both the relative swelling and the spontaneous dissoln. of gelatin is markedly less at lower temps. The curves are similar to those obtained by von Neuenstein (*C. A.* **22,** 1472) for the spontaneous soln. of cellulose derivs., and it is therefore considered that gelatin is a mixt. of "state-isomerides" having different spontaneous soln. tendencies. B. C. A.

Flow of starch pastes at high and low rates of shear. F. D. Farrow, G. M. Lowe and S. M. Neale. *J. Textile Inst.* **19,** 18-31T(1928).—The flow of starch pastes and of castor oil in capillary and Couette viscometers have been measured at 20° over a range of shear of 300,000-fold; within this range the viscosity of castor oil is const. A method is described whereby the results of viscosity measurements in these instruments may be used to calc. the simple shearing stress and velocity gradient at a definite point in the fluid. A graph of the values so obtained expresses in a manner independent of the instrument the variation of flow with shearing stress for the liquid investigated. The stress-shear curve for starch pastes is quite continuous and either passes through or terminates close to the origin. While it does not hold even approx. over the whole of the range examd., the relation $F^N = \eta dv/dy$ appears to describe the flow of starch pastes better than any other two-const. equation and serves as a useful and accurate interpolation formula within the range usually covered by any one type of instrument. Results of measurements made in capillary tubes are expressed in terms of stress and strain, and therefore made independent of instrument dimensions and comparable with data obtained by the use of other forms of viscometer, by the use of a formula based on the above relation, *viz.*, $(Pr/2l)^N = \eta(V/t)(N + 3)/\pi r^3$, where r is the radius and l the length of the tube, P the driving pressure, and V the vol. of liquid flowing in time t. The method is applied to results given by Freundlich and Schalek (*C. A.* **18,** 1598) for the flow of benzopurpurin sols in both capillary and rotating-cylinder viscometers, and it is shown that the discrepancy between the apparent viscosities as detd. by the 2 methods then disappears. B. C. A.

Solubility of copper in milk. E. I. Soloman with G. N. Quam. Coe College, Cedar Rapids, Ia. *Proc. Iowa Acad. Sci.* **34,** 216-7(1927).—The solubilities of Cu in sweet whole raw milk held at a const temp. for 30 min. were detd. for temps. ranging from 20° to 100°. Cu sheets of known dimensions were totally immersed and agitated in milk for 30 min. at the specified temp. Soly. values were detd. by difference in wt. of the Cu sheets and also by detg colorimetrically with K ethyl xanthate the Cu present in the ash of the milk. Solubilities per unit area increase with rise in temp. up to 80°. W. G. Gaessler

Effect of the position of substitution on the ionization constants of some organic acids. D. A. MacInness. Rockefeller Inst. for Med. Res. *J. Am. Chem. Soc.* **50,** 2587-95(1928).—The ionization consts. of Cl- and OH-substituted aliphatic acids follow the formula $\log K_a = C + S(1/d)$ in which $d = 1$ for the α position, 2 for β, etc. This equation follows if the substituting and COOH groups repel each other according to the inverse square of the distance between their polar bonds and if the free energy of ionization is increased in proportion to the mutual potential energy of the 2 groups. Cl derivs. of PhCOOH follow the formula accurately if the o distance = α distance and a slightly puckered ring structure for C_6H_6 is assumed. Br- and I-substituted aliphatic acids show small systematic deviations. Corresponding aromatic compds. agree closely. Foster Dee Snell

Detection of small differences in the hydrogen-ion concentration of solutions. W. Kesting. *Z. angew. Chem.* **41,** 358-60(1928).—Malononitrile reacts with α-naphthoquinone in solns. of $p_H > 2.5$ with the formation of an intensely blue soln., and the speed of the reaction increases with an increase in the p_H value. To compare the p_H of two solns., 5 cc. of each is placed in sep. test tubes and 5 drops of a 0.2% alc. soln. of malononitrile added to each, followed by 5 drops of a 0.3% alc. soln. of α-naphthoquinone. After shaking, the intensities of the colors are compared; differences of only 0.2 in the p_H value are readily apparent after a little practice In solns.

with $p_H > 11.5$, the addn. of the above reagents produces a green color and the test is no longer of value; in this case β-naphthoquinone is used instead of the α-compd. and the intensities of the red color produced in standard and test are compared. For solns. with relatively low p_H values benzoquinone gives more delicate color changes than either of the naphtho derivs. B. C. A.

Dissociation constant of glutimic acid. Vl. Zafouk. *Listy Cukrovar.* **46,** 631–4(1928).—By means of various methods and the app. described previously (*Listy Cukrovarnicke* **46,** 419(1927–28), the dissocn. const. was found to be (5.9×10^{-4}) at 25° and in dilns. ranging $M/16 - M/32$. Its const. lies between that of tartaric (9.7×10^{-4}) and lactic (1.3×10^{-4}) acids. It constitutes one of the stronger acids found in molasses. Frank Maresh

Influence of neutral salts on acid-salt equilibria. II. Dissociation constants of citric acid. I. M. Kolthoff and W. Bosch. *Rec. trav. chim.* **47,** 558–75(1928); cf. *C. A.* **21,** 3524.—Measurements have been made of the p_H of mixts. of citric acid and its K salts at 18°, and the 3 dissocn. consts. of citric acid calcd. These are $K_1 = 8.2 \times 10^{-4}$, $K_2 = 1.77 \times 10^{-5}$, $K_3 = 3.9 \times 10^{-7}$. The effect of neutral salts on the p_H of the solns. has been studied. Anions are relatively inactive, but there is a well-marked cation effect in the order (Cs, Rb) < K = NH_4 < Na < Li. The influence of KCl can be calcd approx. from the Debye-Huckel equation, but this does not give good results for Na and Li salts. The calcd. av. size of the ions in mixts of di- and tricitrate is 6.2×10^{-8}, but a constant value is not obtained for the citric acid-monocitrate mixts., and it seems that the activity coeff. of the undissocd. acid is much larger than unity at moderate concns. It is proposed to replace for practical purposes the true dissocn. consts. quoted above, which refer to infinite diln. by "acid strengths," which represent the true dissocn. consts. corrected for the activity coeff. of the components. B. C A.

The influence of neutral salts on acid-salt equilibria. III. The second dissociation constant of carbonic acid and the influence of salts on the activity of the hydrogen ions in a bicarbonate-carbonate mixture. I M. Kolthoff and Wouter Bosch Univ. Utrecht. *Rec. trav. chim.* **47,** 819–25(1928); cf. preceding abstract.—The second dissocn. const. of carbonic acid at 18° is 4.4×10^{-11}. This value is arrived at by p_H measurements on solns. of mixed Na_2CO_3 and $NaHCO_3$, the calcns. being performed with the aid of the formulas of Debye and Hückel relating activity to ionic strength and ionic size. The influence of the neutral salts, chlorides of Li, Na and K, KBr, KI and K_2SO_4 on the p_H of dil. bicarbonate-carbonate mixts. is also studied. The influence found cannot be explained by the theory of Debye and Hückel. There seems to be a specific interaction of ions which depends on the nature of the cation of the neutral salt and the size and valence of the ions in the acid salt mixt. **IV. Third and fourth dissociation constants of pyrophosphoric acid and the influence of neutral salts on the activity of the hydrogen ions in a ter-quadrivalent and bi-tervalent pyrophosphate mixture, respectively.** *Ibid* 826–33.—In a similar way the *third* and *fourth dissocn. consts.* of *pyrophosphoric acids* at 18° are 2.1×10^{-7} and 4.06×10^{-10}, resp. The influence of neutral salts on the p_H of a very dil. mixt. of ter- and quadrivalent pyrophosphate is much larger than would be expected from the Debye-Huckel equation. This equation, however, fits the facts for the neutral salt effect on the bi- and tervalent mixt. very well, assuming the av. size of the ions of KCl is 3.7×10^{-8} cm. and for NaCl is 2.3×10^{-8} cm. Small traces of Li salts decrease the p_H of a quadrivalent pyrophosphate soln. very appreciably. This has application in analytical chemistry to testing Na pyrophosphate for alk. impurities and in the titration of pyrophosphoric acid as quadrivalent acid. R. E. Gibson

A derivation of the solubility-product law. Warren C. Vosburgh. *Proc. Iowa Acad. Sci.* **34,** 213–4(1927).—Stieglitz (*C. A.* **2,** 2638) pointed out that the derivation of the soly.-product law based on the application of the law of mass action to strong electrolytes is objectionable. Nevertheless many elementary textbooks still give it. Washburn (*C. A.* **4,** 1572) later gave a satisfactory thermodynamic derivation, and Butler (*C. A.* **18,** 2832) has more recently given a satisfactory statistical one. Another thermodynamic derivation is possible by using the now familiar concepts of free energy and activity. Lewis and Randall (*C. A.* **17,** 1918) have pointed out that in a satd. soln. of an electrolyte the mean activity of the ions is const. The reasoning by which this conclusion may be reached is as follows: A solid electrolyte is in equil. with its satd. soln. when the free energy of the solid is equal to the partial molal free energy of the substance in soln., (1) $F_s = \overline{F}_2$. By the definition of activity (2) $\overline{F}_s - \overline{F}_2 = RT \ln(a_s/a_2)$, where a_s is the activity of the solid and $\overline{F}_s$ is its free energy, and a_2 is the

activity of the solute and $\overline{F}_2$ is its partial molal free energy. Combining equations (1) and (2) and simplifying show that the two activities are equal. The activity of the solid is const. at const. temp. and pressure, and so the activity of the solute is const. also. The activity of the solute can be expressed in terms of the activities of its ions without assuming any particular theory of ionization. This gives (3) $a_2 = a_+^{\nu+}.a_-^{\nu-} = (a\pm)^{\nu_+ + \nu_-} = K$, where a_+ and a_- are the activities of the positive ion and the negative ion, resp., and ν_+ and ν_- are the nos. of moles of the 2 ions in one mole of the electrolyte. The mean activity is designated by $a\pm$ and K is a const. Lewis and Randall did not point out that equation (3) is the soly.-product law in an exact form. In sufficiently dil. solns., especially of uni-univalent electrolytes, the ion activities are approx. equal to their concns. Under such conditions concns. can be substituted for activities in equation (3), giving the ordinary form of the soly.-product law. The latter can therefore be expected to hold when the concns. are approx. equal to the activities and to fail when the concns. differ appreciably from the activities. W. G. Gaessler

Condition of strong electrolytes in concentrated solution. I. Nitrates. H. von Halban and J. Eisenbrand. *Z. physik Chem.* **132**, 401-32(1928).—The displacement of anion absorption bands in the presence of cations has been examd. in detail for the nitrate-ion band at 300$\mu\mu$, by using concd. solns. of alkali nitrates and also dil solns. of the nitrates in concd. solns. of other salts. All cations influence the absorption of the nitrate ion, which is in the same condition in a concd. nitrate soln. as in a dil. nitrate soln. having a high cation concn. The less easily deformed the cation, the greater is its influence on the anion, while the dielec. constant of the solvent is of considerable importance as regards the magnitude of the effect. The displacement of the band decreases on passing down a group of the periodic table, and in the case of the alkali metals changes sign. No influence is manifested by heavy-metal cations such as the mercuric, cupric and nickelous ions at the low concns. at which the alkali metals are active. Schäler's observation, that Beer's law is not valid for these nitrates at even low concns., is not due to a change in the absorption of the nitrate ion, but is a cationic effect. Other anions present in the soln. affect the extent, but not the nature, of the displacement. For a given concd. nitrate soln. there exists a dil. nitrate soln. contg a different salt of the same cation, such that the two solns. possess at all wave lengths identical absorption The displacement effect is discontinuous, and is due to the formation of a new type of absorbing mol which contains both the nitrate ion and the cation **II. Nitric acid.** *Ibid* 433-55.—Measurements have been made of the absorption spectrum of HNO_3 in solns. of widely varying concn. in water and in aq. solns of $HClO_4$, H_2SO_4 and H_3PO_4, and also in dil. Et ether, acetic acid, Et alc. and hexane soln. The spectra of the dil. aq. solns are identical with those of the corresponding nitrate solns. At concn. below about 10N the extinction-wave-length curves of all the aq. solns. intersect at a common point. The extreme variations exhibited by the spectrum over this concn. range cannot be ascribed to the presence of undissocd. mols. of HNO_3, and the possible formation of ionic pairs or of complex ions is suggested. In ether and in acetic acid soln., HNO_3 exists to the extent of about 60% as assocd. ions, this is the case for concd. aq. solns., the remainder consisting of undissocd. mols. The spectra of the solns. in hexane resemble those of the esters, the greater part of the acid being undissocd. Solns. in aq. H_2SO_4 have spectra which change from the first type to the second as the H_2SO_4 concn. increases. The totally different spectrum exhibited by concd. H_2SO_4 solns. of HNO_3 is ascribed to the presence of nitric anhydride.

B. C. A.

Refraction and dissociation of electrolytes. I. In water. Erling Schreiner. Oslo Univ. *Z. physik Chem.* **133**, 420-30(1928).—The mol. refraction of CCl_3CO_2H, of Li and Na trichloroacetates, and of HCl and LiCl have been measured in water. The values for the refraction of HCl and LiCl in MeOH and EtOH are given in the next paper (cf. below). The dissocn. ratio of the acid is compared with that for salts S. distinguishes dissocn. (1) $AB \rightleftharpoons A^+ + B^-$ from (2) $A^+B^- \rightleftharpoons A^+ + B^-$. If R be the refraction for electrolytes (acids) at a concn. C, R_0 the refraction at $C = 0$ and R_u the refraction of the undissocd. mol., then $(1 - \alpha) = (R_0 - R)/(R_0 - R_u)$ and the degree of dissocn. $\alpha = (R - R_u)/(R_0 - R_u)$. A difficulty of the method is that deformation diminishes refraction as the concn. increases. If the value for α agrees with the law of mass action it is most probable that the dissocn. belongs to class (1). All ordinary salts exhibit quite const. refraction even up to multimolar concns., but solns. about 2-4 N, particularly in the case of multivalent salts, must be put with the undissocd. mols. of the second class. The incompletely dissocd mol. of class (2) does not appear of significance; *i. e.*, the refraction is the sum of the free ions, a conclusion supported by the incomplete dissocn. of alk. hydroxide. A

new construction Zeiss-Pulfrich refractometer was used and values obtained for the Na_D line and the H_ϵ and H_F lines. A Sprengel pycnometer was used in the density detns. Concns. were detd. by weighing. The CCl_3CO_2H was vacuum, distd. **II. In methanol and ethyl alcohol.** *Ibid* **135,** 461–72.—The linear diminution of refraction for HCl at high concns. could not be taken as due to incomplete dissocn. either of the first kind (cf. above) or of the second kind, but must be ascribed to a deformation effect of ions upon solvent. The result can also agree with the finding that aq. HCl is for the most part incompletely dissocd and has a dissocn. const. of 10^4–10^6. The dissocn. const. of HCl in EtOH should be about 10^{-1} and the refractometric methods was used to ascertain the state of HCl in EtOH and also of LiCl in MeOH and EtOH which was used in comparison. The MeOH was dried with Mg turnings and the EtOH with CaO and Ca or amalgamated Al turnings Dryness was established by cond. measurements. LiCl was heated with abs. EtOH, the liquid treated with $(NH_4)_2CO_3$, warmed and filtered. The filtrate was acidified, taken to dryness and the NH_4 salts volatilized off. The residue was dissolved, acidified, filtered, evapd. and dried at 150°. The mol. refraction of HCl and of LiCl in MeOH was detd. at 18° for the C, D and F lines, and of LiCl and HCl in EtOH. A salt like LiCl appears completely dissocd. in water and both alcohols and a dissocn. of the second kind in media of low dielec. const. and up to about 2.5 *N* may be neglected in the alcohols. The refraction for HCl in MeOH and EtOH is linear with concn. The figures for HCl and LiCl in water, MeOH and EtOH are explicable on the assumption of monosolvation of the H ion, *i. e.*, H^+HOH, H^+CH_3OH, $H^+C_2H_5OH$ and the same for the Li ion. The refraction values for HCl and LiCl at infinite diln. fall in the order: water, MeOH, EtOH.

The electrolytic dissociation of dibasic acids. IV. The dissociation constants of some mercaptomonocarboxylic acids. Erik Larsson. Lund-Univ. *Z. anorg. allgem. Chem.* **172,** 375–84(1928).—The first and second dissocn. consts. of the following acids were detd. Thioglycolic acid, 2.1×10^{-4}, 2.1×10^{-11}, α-thiolactic acid, 2.0×10^{-4}, 2.0×10^{-11}; β-thiolactic acid, 0.46×10^{-4}, 2.9×10^{-11}, α mercaptoisobutyric acid, 1.26×10^{-4}, 0.48×10^{-11}. The first dissocn. consts. were detd. from conductivities, the second from colorimetric measurements with known indicators. These are gross dissocn. consts. as both the first and second ionizations involve two dissocns., the acids being dibasic and unsymmetrical. However, L. shows that in the first stage the strength of the COOH group in the undissocd acid mol. preponderates while in the second stage of ionization the mercaptan group of the univalent acid anion is the predominating factor.

R. E. Gibson

Migration of ions from aqueous solutions into glass. Franz Quittner. *Ann. Physik* [iv] **85,** 745–69(1928).—The migration of cations from metal salt solns. and of H ions from acid solns. into 4 Schott glasses at 52° and $2 - 6 \times 10^5$ volts/cm field strength has been investigated. The percentage of the total current carried by alkali metal ions is characteristic for the various glasses and rises with increasing concn of the soln. used as anode. Ag ions wander the most freely, while Ca, Ba, Zn and Cu, when at all, wander only feebly. With an acid soln. or a $Ba(OH)_2$ soln. as anode, the current for the greater part is due to H ions.

B. C. A.

Electrical conduction in solutions, and the determination of electrical conductivity. K. Sándera. *Listy Cukrovar.* **47,** 9–14(1928).—Problems are given to illustrate the effect of size and shape of cond. cells upon the course of elec. conduction so that abnormal and disturbing effects encountered in the practical application of elec. cond. measurements may be predicted and avoided.

Frank Maresh

The role of phosphates in the oxidation of glucose. A. N. Kappanna. *J. Indian Chem. Soc.* **5,** 387–96(1928).—The oxidation of *glucose* by *iodine* to *gluconic acid* takes place in alk. soln. The reaction rate at 22° increases with increasing p_H. In neutral solns. and in a phosphate soln. buffered to $p_H = 7.0$, the reaction does not occur. At const. alky. the rate is independent of the phosphate concn. Results indicate that no hexose-phosphate complex is formed. In the *decompn. of H_2O_2* in water at 60° the results indicate that no phosphate-H_2O_2 complex is formed. The rate of decompn. at const. alky. is independent of the phosphate concn. The velocity increases with increasing p_H.

Paul J. Culhane

The nitronium or nitracidium salts and the cationic wandering of nitric acid. A. Hantzsch and Kurt Berger. *Ber.* **61B,** 1328–34(1928).—The nitracidium ion is that such as is formed by the interaction of abs. $HClO_4$ and HNO_3 to form $[O_2NOH]^+$ and $[N(OH)_3]^{++}$. The cond. of nitracidium perchlorate is detd. in abs nitromethane as a binary electrolyte. The molar cond. is a min. at $v = 120$, corresponding to $\mu_v = 14$; $\mu_\infty = 135$. Similarly the hydronitracidium perchlorate

$[NO_3H_3](ClO_4)_2$ is a ternary electrolyte; the value of $\mu_\infty = 200$. This proves the cationic wandering of HNO_3 as nitracidium, especially in pure nitromethane, which is further demonstrated by analysis of cathode liquid in a migration app. G. L. C.

The constitution of acids and salts and their chemical changes in solution. A. HANTZSCH. *Z. physik. Chem.* **134**, 406–12(1928).—The usual distinction between pseudo acids, *e. g.*, $XO_2 \cdot OH$, and true acids, XO_3H, is meaningless inasmuch as the latter do not exist. Liquid oxygen acids exist as $XO_2 \cdot OH$ or an associated form of this and are changed by water to an oxonium salt, $[XO_3]H_3O$. H. redefines the term acid and mentions methods for detg. the degree of acidity. Salts may exist as true or pseudo salts; the latter class includes the salts of the heavy metals. LUCY K. PICKETT

The chemical changes of acids and salts in solution on the basis of refractometric data. A. HANTZSCH AND F. DURIGEN. *Z. physik. Chem.* **134**, 413–52(1928).—The paper is a discussion of exptl. results. The mol. refraction is a measurement of the space occupied by the mol.; hence its changes may be ascribed to a deformation of the electron system due to either physi al or chem. changes. The shifting of the refraction of acids and salts in soln. is primarily caused by chem. change. The refractive power of an acid is raised in the change of a pseudo acid to its hydroxonium salt (cf. preceding abstract) and lowered in the hydration of the latter. True salts show only the second effect if any, while pseudo salts should show both. The behavior of nitric acid at high concns is ascribed to a change from nitronium nitrate to the pseudo acid. The agreement of results obtained by refraction and light absorption methods, supplemented by cond. data, is discussed. *Ibid* **136**, 1–17(1928).—The exptl. results obtained by the authors and other investigators for the mol. refraction of aq. and alc solns. of various concns. are tabulated for the following acids and their salts. $HClO_4$, HCl, HBr, HI, HNO_3, H_2SO_4, HCOOH, CH_3COOH, CH_3CH_2COOH, $CH_2ClCOOH$, $CHCl_2COOH$, CCl_3COOH, $CH_2BrCOOH$, $CH_3CHBrCOOH$, $C_6H_5SO_3H$.

Quantum statistics applied to irreversible reactions. TH. DE DONDER. *Bull. sci acad roy Belg.* **14**, 135–9(1928); cf de Donder, *Ibid* **13**, 303(1927).—A mathematical treatment of a previously considered irreversible reaction using the recent results of Brillouin, *Ann. phys.* **7**, 315(1927) and Bothe (*C. A.* **22**, 1890).
ARTHUR FLEISCHER

The influence of salts on the solubility of other salts in non-aqueous solutions. CHARLES A KRAUS AND RALPH P. SEWARD Brown Univ. *J. Phys. Chem.* **32**, 1294–1305(1928) - The solubilities of NaBr in the presence of $NaNO_3$ in Me_2CO, NaCl in the presence of $NaNO_3$ and NH_4NO_3 in Me_2CHOH and of NaCl in the presence of $NaNO_3$ in hydrated Me_2CHOH were measured at 25°. The soly effects in these solvents resemble those in H_2O, *i e*, the soly of a given salt is depressed by the addn. of a second salt with a common ion and is increased by the addn of a second salt without a common ion. The soly. depression in these solvents is about 1/4 that in H_2O, while the increase on addn. of a salt without a common ion is about 4 times as great as that in H_2O. The observed effects are much smaller than those predicted by the interionic attraction theory of Debye and Hückel. It is suggested that, in solvents having dielec consts of intermediate values, electrolytes are incompletely ionized. The idea of interionic attraction should be supplemented by other assumptions, such as the nearness of approach of the ions and the spatial configurations of their electronic systems.
H. F. JOHNSTONE

The kinetics of oxidation of organic substances with bromine. I. Effect of bromine on oxalic acid. EDWARD JÓZEFOWICZ. *Roczniki Chem.* **8**, 123–51(1928).—At 20° in 1/20 to 1/80 *N* soln. the reaction is detd. by: $dx/dt = K_0(a-x)^2/x^2$. Br_2 apparently reacts not with the undissocd. mol., but with the anion; hence the reaction velocity is increased by diln., by the progress of oxidation and by the addn. of Na_2SO_4 and decreased by HBr, bromides, HNO_3, HCl. For HBr: $dx/dt = K_0(a-x)^2/(c+x)^2$, for bromides: $dx/dt = K_0(a-x)^2/(^3/_5c+x)^2$ and for HCl and HNO_3: $dx/dt = K_0(a-x)_2/(^1/_5\ c+x)^2$. Chlorides have no perceptible effect. The temp. coeff. is 4.52 between 10° and 20°. The oxidation of *acid oxalates* by Br_2 follows the same equation, but dx/dt is 3 times higher For *neutral oxalates* dx/dt is too high to permit any kind of measurement. Previous authors have assumed that Br_2 reacts as such with $C_2H_2O_4$ and that Br^- forms with Br_2 Br_3^- which takes no part in the reaction. This, however, would mean a reaction of 2nd order, while it actually is of 0 order. It also would call for an inhibition of the reaction by Cl^-, since they are capable of binding Br_2 to $ClBr_2^-$, while the reaction is less inhibited by HCl than by HNO_3 and even slightly accelerated by chlorides. If, however, we assume that $C_2O_4H^-$ reacts with HOBr formed by hydrolysis from Br_2 we obtain for dx/dt the equation found exptly

This theory, however, does not account for the greater effect of Br^- over H^+. Possibly $C_2O_4^{--}$ also reacts according to Roloff, but in view of the slight dissocn. of $C_2O_4H^-$ this reaction can be only of secondary importance. MARY JACOBSEN

The solubility of potassium ferricyanide in water between 0° and 100°. JOHN A. N. FRIEND AND WM. N. SMIRLES. Techn. College, Birmingham, Eng. *J. Chem. Soc.* **1928**, 2242–5.—Contrary to the results of Vallance (*C. A.* **21**, 3297), the authors do not find a break in the soly. curve of $K_3Fe(CN)_6$ in H_2O between 0° and 100°. The soly. in g. per 100 g. of H_2O is given by the equation, $S = 30.4 + 0.80t - 0.0020t^2$. The ds. of the satd. solns. at various temps. were also detd. The d. curve also shows no irregularity. H. F. JOHNSTONE

The solubility equilibrium of crystallized zinc hydroxide in sodium hydroxide. R. FRICKE AND H. HUME. *Z. anorg. allgem. Chem.* **172**, 234–42(1928).—The previous work on the soly. of amphoteric hydroxides in solns. of strong alkalies done by Fricke and his collaborators and by other investigators is reviewed. Additional work with data is presented to show the variation of soly. of $Zn(OH)_2$ with the concn. of alkali, excess of solid $Zn(OH)_2$, and time of contact. Gravimetric and volumetric methods for the analysis of this type of soln. and the probable formulas of the possible Na zincates are discussed. W. J. SWEENEY

Solubility relations of isomeric organic compounds. VIII. Solubility of the aminobenzoic acids in various liquids. CHARLES L. LAZZELL AND JOHN JOHNSTON. Yale Univ. *J. Phys. Chem.* **32**, 1331–41(1928).—The solubilities of each of the 3 aminobenzoic acids from 25° to its melting temp. have been detd. in benzene, $CHCl_3$, EtOH and EtOAc. A few detns. in MeOH and BuOH were made and related to those in EtOH. The results are compared with data from the literature on other mono-substituted benzoic acids and on the nitroanilines. Irregularities in these correlations indicate that solubilities of closely related compds. are influenced both by solvent and solute. W. T. RICHARDS

Mechanism of oxidation processes. XIV. Activation of oxygen by iron. HEINRICH WIELAND AND WILHELM FRANKE. Bayr. Akad. Wissenschaften zu München. *Ann.* **464**, 101–226(1928); cf. *C. A.* **22**, 2574.—The autoxidation of solns. of ferrous salts has been studied with AcONa and AcOH as a buffer. Absorption of O follows the unimol. law. The temp. coeff. of the process is normal, while a change from p_H 5 to 7 accelerates the reaction 4 or 5 times. At p_H 5, neutral salts have little effect on the rate of autoxidation, although Na_2SO_4, possibly because it produces complex salts, causes diminution of the reaction velocity to 0.5 its previous value. The rate of autoxidation of slightly hydrated $FeCl_3$ is greater in Me_2CO than in EtOH or iso-PrOH, greater in these solvents than in MeOH and least in H_2O. The autoxidation of a no. of acids in the presence of Fe salts has been studied. In general $FeSO_4$ is the added Fe salt and an acetate buffer is used. *Formic acid.*—Autoxidation of the ferrous salt induces autoxidation of formate, the latter ceasing when no more ferrous salt remains, since ferric Fe does not oxidize HCO_2H. *Lactic acid*—Autoxidation of the lactate is more rapid than that of the formate, about $^1/_3$ of the O absorbed by the system during the complete oxidation of the Fe being used to oxidize the lactate to CO_2, AcH and (some) pyruvic acid. Autoxidation is most rapid at p_H 8.0 and is slower in air than in pure O. *Pyruvic acid.*—This case is very similar to that of lactic acid: in neither case does ferric Fe oxidize the acid. *Tartaric acid.*—This autoxidation is investigated very fully. Small changes in conditions very greatly affect the progress of the reaction. Ferric salts do not initiate autoxidation of tartaric acid but play a considerable part in the autoxidation of the acid in the presence of ferrous salts, since the dihydroxymaleic acid (I) formed is oxidized by ferric, producing ferrous salts The autoxidation proceeds much further in acid than in neutral solns. and has a normal temp. coeff. up to 20°. At 30°, however, the process is not appreciably quicker than at 20°. To some extent, the process is catalytic in nature, because of the reduction of ferric salts by the I formed. I acts as a strong positive catalyst for a similar reason The autoxidation process is greatly accelerated by Na_2SO_4 and somewhat accelerated by $NaNO_3$ or by $CuSO_4$, while NaCl, NaI and NaBr act as strong retardants. *p*-$C_6H_4O_2$ also has a retarding effect. Increased pressure of O accelerates autoxidation, but the total amt. of O used is less than is the case with lower pressures. *Dihydroxymaleic acid.*—Because of the slight soly. of the K and Na salts of I, buffering is best effected by AcOH and AcOLi. The spontaneous decompn. of a buffered soln. (p_H 4.8) of I (atm. of N) is markedly affected by ferrous salts. Substitution of phthalate for acetate as a buffer has only a slight effect. Phosphate produces marked retardation and addn. of pyrophosphate in addn. further retards the velocity of autoxidation. Buffering with glycine causes acceleration. At p_H 1.4 and 13, autoxidation is markedly

slower than at intermediate acidities, p_H 5 being the optimum condition. The spontaneous autoxidation of I in the absence of Fe proceeds more rapidly in alk. than in acid soln. The main reaction involved is I + $^1/_2$ O_2 $\longrightarrow$ $HO_2CCOCOCO_2H$. Ferric salts oxidize I (p_H 5, AcOH and AcOLi) to diketosuccinic acid, which, during the autoxidation process, gives $(CO_2H)_2$ and mesoxalic acid in the ratio of 1 : 2, the latter slowly giving $(CO_2H)_2$. *Glyceric acid.*—This case is similar to tartaric acid. Added ferrous salt produces an effect roughly proportional to its concn. *Thioglycolic acid.*—Cu salts are in general more positively catalytic of the autoxidation of this acid than are those of Fe, but the latter become more effective in the neighborhood of the neutral point. H_2SO_4 is a product of autoxidation, which is retarded by cyanides. *Hydroquinone.*—The oxidation of this compd. by ferric salts renders the autoxidation of hydroquinone in the presence of ferrous salts similar to that of I. The velocity of change depends very largely on the p_H. Near the neutral point, ferrous salts reduce p-$C_6H_4O_2$ so that the basis of the autoxidation process is $HOC_6H_4OH + 2Fe^{\cdot\cdot\cdot} \rightleftharpoons O{:}C_6H_4{:}O + 2Fe^{\cdot\cdot} + 2H^{\cdot}$. The buffer used may have a considerable effect on the mobility of the equil. Thus, autoxidation is particularly facile in the presence of a AcONa buffer, less so with Na glycerate and much less so with Na phthalate. The catalytic action of Fe salts in this process has its optimum within certain fairly narrow limits of concn. p-$C_6H_4O_2$ has a marked retarding effect on the autoxidation of hydroquinone, probably owing to the formation of an inactive Fe-quinhydrone complex. It is difficult to recognize the mechanism of the autoxidation as one of true catalysis and it may be that ferric salt is the effective oxidant of the hydroquinone. This would explain why in the slow autoxidation of hydroquinone that occurs in the absence of a buffer, ferrous and ferric salts produce effects of a similar magnitude. In buffered solns., ferrous Fe is more powerful in action than ferric, so that probably an O activation process is at work, in this case, on the part of a ferrous salt-acetate complex. *Pyrocatechol.*—Here the accelerative influence of Fe in autoxidation is markedly stronger than with hydroquinone. *Pyrogallol.*—This case is similar to pyrocatechol, but autoxidation is more rapid The product is not purpurogallin but is the amorphous brown substance, resembling a humic acid, obtained in the H_2O_2-Fe oxidation of pyrogallol $K_4Fe(CN)_6$ aids autoxidation but to a much smaller extent than simple Fe salts. Expts. have been carried out on the autoxidation of I in complete absence of Fe salts, to see if the known absorption of O by solns. of I is really due to the presence of unsuspected traces of Fe. While special purification of I (vacuum distn. in quartz) renders it more stable in this respect, Fe is not the initiator of the process but merely catalyzes a reaction in progress. This is supported by the fact that, in neutral solns. of the purified material, cyanide slightly accelerate autoxidation, whereas in the presence of traces of Fe, it markedly diminishes the acceleration due to the latter. Similar results have been obtained with hydroquinone. The autoxidation of hydroquinone itself produces H_2O_2 at p_H 3.6, while when Fe is present no H_2O_2 is formed. *Arsenious acid.*—According to Manchot (*Z. anal. Chem.* **27**, 420(1901)) 1 equiv. of O is activated during the oxidation of $Fe^{\cdot\cdot}$ to $Fe^{\cdot\cdot\cdot}$ and is used for the conversion of arsenite to arsenate. This is not actually realizable under all conditions of acidity. The most concd. weakly alk. soln. (p_H 6) of arsenite obtainable shows an activation of only 0.88 equiv. For p_H 10, corresponding with $NaAsO_2$, activation corresponds to 0.6 equiv. and for more strongly alk. solns., corresponding with Na_2HAsO_3, it corresponds with not more than 1 equiv., in opposition to Gire's results (*C. A.* **14**, 3027). When alky. corresponds to Na_3AsO_3, activation exceeds 1 equiv. of O, the extra (0.5 mol.) activation being due to spontaneous autoxidation and not to oxidation of arsenite by ferric salts. *Hypophosphorous acid.*—This acid is not appreciably oxidized by O in the absence of Fe salts. The autoxidation in the presence of Fe salts seems to be an induction effect, ceasing when all ferrous salt has become oxidized. It is little affected by p_H. The results appear to show that the activation of mol. O by ferrous salts cannot be due to the intermediate formation of a peroxide, as suggested by Manchot. It is probable that the 1st stage in the autoxidation is the formation of a complex between the ferrous salt and the hypophosphite, rendering the H of the latter more active as regards oxidation. The 2nd stage is the very slow reaction $2Fe^{\cdot\cdot\cdot} + H_3PO_2 \xrightarrow{H_2O} 2Fe^{\cdot\cdot} + H_3PO_3 + 2H^{\cdot}$. H_3PO_3 behaves similarly to H_3PO_2 but the activation is less pronounced and is more influenced by the acidity conditions. Certain combined autoxidations have been studied. The autoxidation of H_3PO_2 in the presence of ferrous salts and I is catalytic in type, the p_H of the soln. not greatly affecting the rate of change. Diketosuccinic acid (not tartaric or glyceric acid) behaves similarly to I but it is only slowly oxidized by ferric salt, whereas the latter is instantaneously oxidized by ferric salt in the presence of H_3PO_2. The mech-

anism of the combined autoxidation is discussed. Possibly a readily dehydrogenated ferric salt-diketosuccinic acid complex is formed as an intermediate. The autoxidation of HCO_2H in the presence of ferrous salts is accelerated by I but the acceleration is less than in the above case of H_3PO_2. Diketosuccinic acid is again an active intermediate. Relatively large amts. of I are required to produce acceleration and the same is the case in the autoxidation of lactic acid in the presence of ferrous salts. I produces no acceleration of the autoxidation of hydroquinone-ferrous salts. The autoxidation of HCO_2H-ferrous salt in the presence of thioglycolic acid is similar to the above case of HCO_2H-I The acid does not accelerate autoxidation until present in a certain concn. but after this is reached its effect is proportional to its concn. When lactic acid replaces HCO_2H there is a more pronounced mutual activation, while when tartaric acid is used, less thioglycolic acid is required to accelerate the (more rapid) autoxidation. The autoxidation of H_3PO_2 and ferrous salts in the presence of thioglycolic acid is a case of true catalysis, due to the equil. between $Fe^{\cdot\cdot}$-thioglycolic acid and Fe -dithiodiglycolic acid. This equil. must lie mostly on the $Fe^{\cdot}$ side, because of the marked initial activation which precedes the main, catalytic, stage. Activation is ascribed to the formation of a thioglycolic acid-ferrous salt complex. The autoxidation of H_3PO_2 in the presence of ferrous salts is not accelerated by pyruvic acid but the autoxidation of pyruvic acid in the presence of H_3PO_2 is markedly accelerated by traces of ferrous salts, giving a case of true catalysis. Some consideration is given to cases of direct addn. of O to an unsatd. linking, as distinguished from the above cases, in which H is removed from a substance. The autoxidation of linolenic acid and of lecithin is also discussed. C. J West

Velocity coefficients for bimolecular reactions in solutions. D. H. Peacock. *Nature* **122**, 131–2(1928).—A discussion of energy exchanges between solvent mols and mols. of a reacting solute; activated mols. (*C. A.* **22**, 1518, 2506). P. raises the question of electron tautomerism in this connection. G R Yohe

Solubility of alkali soaps in hydrocarbons. Josef Weichherz. Tierärztliche Hochschule, Berlin. *Naturwissenschaften* **16**, 654(1928) – It was found that highly viscous or gelatinous solns of alkali soaps in hydrocarbons can be made; small quantities of PhOH, alcohols and water promote the soly. At normal temps the soaps swell slightly, more at high temps., in hydrocarbons. At high soap concns the formation of water-in-oil emulsions was observed, reversing to oil in-water on lowering the concn No details are given. B J. C. van der Hoeven

The chemical reactions of carbon monoxide and hydrogen after collisions with electrons. A. Caress and E. K. Rideal. *Proc Roy. Soc.* (London) **A120**, 370 8. (1928); cf. *C. A.* **21**, 3548.—The method used in this study was a previously published one with some improvements. The rates of the reaction at various voltages with const electron current and efficiencies were detd For pure CO the main reaction 2CO → C + CO_2 occurred above the arcking potential A small quantity of C_3O_2 was probably formed. With equimol. mixts. of CO and H_2 decrease in pressure was always observed even with a zero voltage when the filament temp. was high enough. The reaction of H atoms with CO ions was more rapid than that between the atom and mol. H ions did not appreciably enhance the speed. In the products of reaction no CH_4, H_2O, C or CH_3OH was found. When the tubes were allowed to warm to room temp. the pressure decreased following a unimol law and a white solid deposited on the walls. This reaction was the polymerization of liquid formaldehyde to trioxymethylene. For every ion formed more than 1 mol. of CO reacts so that some kind of chain mechanism must be operative in the reaction. Arthur Fleischer

Surface solutions. R. Delaplace. *J. phys. radium* **9**, 111–9(1928).—An app is described for measuring the pressure and area of surface solns., and the pressure-area temp. relations of surface solns. of benzyl benzoate are examined at pressures of 0 1 0.001 dyne/cm, and at 15° and 27°. The laws of Boyle, pS = const., and of Gay Lussac, $pS = kT$, where p is the surface pressure, S the area of the surface, and k a const., were verified. The value of k is much smaller than that of R, the gas const Attention is directed to the difference in exptl. conditions between D.'s work and that of Adam and Jessop (*C. A.* **20**, 1542, 1544). B. C. A

Velocity of ionic reactions. III. R. N. J. Saal. *Rec. trav. chim.* **47**, 385 96 (1928).—By the oxidation-potential method previously described (*C. A.* **22**, 1263, 1714), the velocity coeff. of the bimol. reaction between ferrous and persulfate ions has been detd. in different concns. of KCl, $MgCl_2$ and $MgSO_4$. Practically the same values were obtained with equiv. concns. of excess of neutral salt. This is not in accordance with theory and might be ascribed to the accelerating influence of the Mg ion. It is shown that the catalytic influence of Fe salts on the reaction between per-

sulfate and I, observed by von Kiss and von Zombory (*C. A.* **21**, 2593), cannot be wholly explained by the reactions $2Fe^{\cdot\cdot} + S_2O_8'' \longrightarrow 2Fe^{\cdot\cdot\cdot} + 2SO_4''$ and $2Fe^{\cdot\cdot\cdot} + 2I' \longrightarrow 2Fe^{\cdot\cdot} + I_2$. The amt. of I formed by catalysis, as calcd. from the coeff. of these reactions, is much smaller than that found by expt. The velocity coeff. of the bimol. reaction $I_2 + Fe(CN)_6''''$ has been detd. in the presence of 0.1 and 1 *N* KCl, and the latter is found to have a strong retarding action which is not in accordance with Brønsted's theory. B. C. A.

The theory of the acid-base function. J. N. Brønsted. *Ber.* **61B**, 2049–68 (1928).—An acid is defined as a compd. which can lose a proton, while a base is a compound which can add a proton. The acid-base function and the hydration effect believed to exist are explained. The strength of acid and base in benzene may be explained also with the above definition. Equil. consts. and their significance are discussed. The following acids arranged as to the order of their strength in benzene have been studied: HCl, methyl red, dimethyl yellow, CCl_3CO_2H, $CHCl_2CO_2H$, picric acid, o-nitrobenzoic acid, CH_2ClCO_2H, salicylic acid, bromophenol blue, β-dinitrophenol, *o*-chlorobenzoic acid, neutral red, *m*-chlorobenzoic acid, bromoresol green, benzylammonium ion, formic acid, phenylacetic acid, BzOH, AcOH, isoamylammonium ion, bromocresol purple, piperidinium ion and bromothymol blue. Raymond H. Lambert

Hydrolysis in solutions of potassium laurate as measured by extraction with benzene. James W. McBain and Monroe Eaton. Stanford Univ. *J. Chem. Soc.* **1928**, 2166–79.—The compns. of C_6H_6 solns. of lauric acid in equil. with various solns. of K laurate at 25° were detd. Unaltered soap solns. contain a slight trace of free fatty acid—a small percentage of the amt. which can be dissolved in water. The fatty acid which corresponds to the hydrolysis alky. is almost quantitatively combined as acid soap. An acid soap in the form of sediment is produced when CO_2 is in contact with soap solns. K laurate, both solid and in aq. soln., extracts lauric acid from its concd. solns. in C_6H_6, forming acid soap. The existence of a definite cryst. compd. (acid potassium laurate, KL.HL), sol. in hot C_6H_6, is shown. Soap is almost quant. removed by a concd. soln. of lauric acid in C_6H_6. The presence of salts promotes the formation of acid soap, but diminishes the extractability of aq. soap soln. A. J. Currier

The decomposition of hydrogen peroxide in the presence and the absence of sodium hydroxide. Constantin Pana. Muspratt Lab. of Physical and Electro-Chem., Univ. of Liverpool. *Trans. Faraday Soc.* **24**, 486–92(1928).—The decompn. of H_2O_2 was detd. for 0.5 and 1.5 *N* solns. at 40°, 50° and 60° in aq. and in 0.008, 0.013 and 0.025 *N* NaOH solns. in freshly blown glass, wax-covered glass and silica containers. The results in wax were taken as due to the dust in the soln. and these values were subtracted from the values in glass and silica to get the true values for those surfaces. NaOH lowers the critical increment while raising the initial velocity of decompn. With increase in H_2O_2 concn. the critical increment increases and the velocity of decompn. diminishes. In the presence of alkali increasing $Fe(OH)_3$ concn. lowers the rate of decompn. A pos. catalytic effect may be ascribed to the hydroxyl ion. A. F.

The reciprocal couple: $2NaCl + Ba(ClO_3)_2 = 2NaClO_3 + BaCl_2$. C. Di Capua and A. Bertoni. R. Univ. di Firenze. *Gazz. chim. ital.* **58**, 249–53(1928).—Isotherms of the systems: $NaClO_3$–$NaCl$–H_2O, $NaCl$–$BaCl_2$–H_2O, $BaCl_2$–$Ba(ClO_3)_2$–H_2O and $Ba(ClO_3)_2$–$NaClO_3$–H_2O are given in tables and diagrams for 20°. From these data it is shown that at 20° $Ba(ClO_3)_2$–NaCl is the stable couple. Further data in diagrammatic form show the compn. in g.-equivs. of quaternary solns. C. C. D.

Reactions between carbon monoxide, carbon dioxide and hydrogen in a "cold-warm" tube at atmospheric and high pressures. F. Fischer and F. Wangenheim *Brennstoff-Chem.* **9**, 94–7(1928).—A *special steel bomb* is used in which the contact metals serve as elec. resistors. Metals used were: Fe, Ni, W, Mo and also C, named in order of their catalytic activity. Various mixts. of CO and CO_2 with H_2 were used. C was produced, and also CH_4, with traces of higher homologs in some cases. Traces of HCHO were formed, but no CH_3OH. Temps. of 550° to 800° were used. J. D. D.

Some gas reactions in a "cold-warm" tube. F. Fischer and F. Wangenheim. *Brennstoff-Chem.* **9**, 97–8(1928).—App. designed (cf. preceding abstr.) to investigate catalytic reactions of mixts. of CO and H_2 was used with Fe as a catalyst. Mixts. of CO, CO_2, H_2O and CH_4 were investigated at 600–700° and up to 6 atm. CH_4 remained practically unchanged. Reactions taking place were: (1) $2CO \longrightarrow CO_2 + C$ and (2) $CO + H_2O \longrightarrow CO_2 + H_2$. J. D. Davis

Measurement of hydrolysis in stannous salt solutions. Milda Prytz. Copenhagen. *Z. anorg. allgem. Chem.* **174**, 355–75(1928).—The solns. used were prepd. in an atm. of H and great care was taken in the work to prevent the formation of any

stannic salt. A series of potentiometric titrations of stannous salt solns. with NaOH was carried out at 25°. The results are presented graphically in a series of curves. The first portion of each curve corresponds to the neutralization of the free acid present; the second portion (a vertical line) to the formation of a basic ppt., probably $Sn(OH)_2$; the third portion, obtained when the NaOH added is about 2 equiv. per atom Sn, is again an ascending curve. On the assumption that hydrolysis proceeds in such a way that the $Sn(OH)^{\cdot}$ ion goes over into $Sn_2(OH)_2^{\cdot\cdot}$ or $Sn_2O^{\cdot\cdot}$, the hydrolysis const. $K = (\alpha^3/(1-\alpha)^2)m$, where m = molar concn. of stannous salt and α = degree of hydrolysis. The following values of K were found: 0.08×10^{-3} for $SnCl_2$ contg. 0.5 M KCl; 2.0×10^{-3} for $SnCl_2$; 0.58×10^{-3} for $SnBr_2$ contg. 0.5 M KBr; 8.3×10^{-3} (value uncertain) for $SnBr_2$; 1.8×10^{-3} for $Sn(ClO_4)_2$. The soly. product of $Sn(OH)_2$ was found to be about 5×10^{-26}. The decrease in concn. of the stannous ions was followed by means of a titration in which a Sn electrode was used in place of the usual H electrode. The results agreed well with those to be expected according to the other calcns. At the OH^- concn. used there was apparently no formation of stannite. LOUISE KELLEY

Decomposition of water and aqueous chloride solutions by iron powder. STANISLAW MICEWICZ. *Przemysl Chem.* **11**, 501–11(1927).—Rates of evolution of H_2 by Fe powder added to water and aq. solns. of NaCl, KCl, $CaCl_2$ and $MgCl_2$ at 100° and a little higher were measured. NaCl and KCl diminish this rate, $CaCl_2$ increases it a little, and $MgCl_2$ increases it very much. In this last case some Mg is pptd. as the oxide or hydroxide, and some Fe remains in soln. Nitrobenzene was reduced by heating on a water bath a mixt. of a soln. of $MgCl_2$ with $C_6H_5NO_2$ and Fe powder. $(C_6H_5NH_2)_2MgCl_2.6H_2O$ forms as a gelatinous ppt. It is refluxed to disappearance of $C_6H_5NO_2$, dild. with water, treated with alkali and $C_6H_5NH_2$ is steam-distd. A. C. ZACHLIN

The theory of acidity. LOUIS P. HAMMETT. Columbia Univ. *J. Am. Chem Soc.* **50**, 2660–73(1928).—A generalized theory of acidity is proposed and given mathematical expression In this the effect of basicity and of the dielectric const. of the solvent are both considered. The predictions of the theory are in agreement with the available evidence in non-aq. soln., notably with the work of Hantzsch and with that of Hall and Conant. R. H LOMBARD

The homogeneous reaction between hydrogen and oxygen. C. H. GIBSON AND C. N. HINSHELWOOD. Oxford. *Proc. Roy. Soc.* (London) **A119**, 591–606(1928) The combination of H and O between 500° and 600° has been studied by a static method in porcelain vessels. Above 500° a homogeneous reaction of high and somewhat variable order becomes manifest; the temp. coeff. is high, and the reaction at higher temps. is retarded by increasing the surface exposed to the gases The rate is approx. proportional to the cube of the H-ion concn and to a power of the O concn. which is greater than unity. The reaction is much accelerated by steam, but the action of steam is not autocatalytic in the ordinary sense since gases like He, N_2 and A have a somewhat similar effect. The results are interpreted on the assumption that reaction chains are propagated through the gas. These chains are broken by deactivation of mols in a heterogeneous reaction at the walls of the vessel, and lengthened by the presence of inert gases, which increase the time during which mols. escape contact with the walls The order of the diffusion coeff. of the inert gas may be correlated with its effectiveness O and H may themselves have an "inert gas effect" in addn. to their concn.-effect influence on the reaction. Collisions of activated O mols. with mols. of inert gases appear to be elastic. The nature of the chain reactions involved is discussed. W. T. RICHARDS

The mechanism of chemical change. I. Promotion and arrest of the mutarotation of tetraacetylglucose in ethyl acetate solution. T. MARTIN LOWRY AND G. GLYN OWEN. *Proc. Roy. Soc.* (London) **A119**, 505–22(1928).—The effect of very small amts of impurities on the velocity of the mutarotation of tetraacetylglucose in AcOEt soln has been studied with very pure materials and carefully cleaned and dried vessels. It was found that the mutarotation could be retarded for several days in a SiO_2 flask which had been heated to redness, after cleaning, and then cooled in a desiccator over P_2O_5. The velocity of mutarotation of the soln. when added to a freshly cleaned and dried (not heated to redness) SiO_2 polarimeter tube was such that the $^1/_2$ change period was from 0.25 to 0.4 day, but if the tube was rinsed with the soln. first this period was increased to 20 days. Addn. of 0.3% H_2O to the soln. increased, but slightly, the initial velocity of mutarotation, which soon returned to the original value, showing that H_2O is not a catalyst for this reaction. One drop of 0.1 N HCl added to the soln. caused a rapid increase in mutarotation. A similar result was obtained with one drop of N NaOH. The mutarotation curves for the latter two cases are inflected instead of

uni-molecular as if the action had been resolved into 2 consecutive stages. Rinsing the polarimeter tube with pure solvent after the expt. with NaOH did not remove the catalyic effect on the soln. so that it appears possible that this is a surface phenomenon.
A. J. King

The rate of solution of zinc in sulfuric acid under pressures up to 347 atmospheres. Thos. C. Poulter and Glen E. Frazer. Ia. Wesleyan Coll., Mt. Pleasant. *Proc. Iowa Acad. Sci.* **34,** 215(1927).—A study was made of the factors influencing the rate of soln. of Zn in H_2SO_4. The conditions of the surface, the local concn. of the acid at the surface of the Zn, and the size and shape of the pieces of Zn were found to be very important factors, while pressures up to 347 atm. have very little direct influence upon the rate of reaction.
W. G. Gaessler

A study of the reactions involved in a system of zinc and sulfuric acid under pressures up to 16,000 atmospheres. Thos. C. Poulter and Glen E. Frazer. Ia. Wesleyan Coll., Mt. Pleasant. *Proc. Iowa Acad. Sci.* **34,** 216(1927).—A continuation of the investigation described in the previous paper. A method has been worked out for following the rate of the reaction at very high pressures in which the pressure can be varied rapidly and the rate of the reaction continuously read. Very little effect upon the rate of the reaction, directly due to pressure, was noticed up to pressures of 6000 atm.
W. G. Gaessler

Development of the concepts concerning the nature of electrolytes. F. Foerster. *Z angew. Chem.* **41,** 1013-21(1928).—A lecture tracing the development of the theories of electrolytes from the time of Arrhenius's paper on ionization (1885) to the present concepts of Bohr, Lewis, Sommerfeld and others. Electrons and nuclei, shells and charges, polar and non-polar compds., Ostwald's law of diln., the solv. product, activity coeffs., osmotic coeffs., cond. coeffs., complex salts, lattice patterns in crystals, hydrates, electrodynamic hydrates, NH_3 system of electrolytes, solvates, etc., come in for crit. reviews. "Our present progress lies in the replacement of such a puzzling process as that of electrolytic dissocn. by a new and unitary concept concerning equil. between ions, on the one hand, and, on the other, between ions and the products formed from them. It is supported upon our knowledge of the nature of ions, of the efficiency of interionic forces, of the dipolar nature of the mols. of solvents, of the deformation of the electronic paths of the ions, and an insight into the arrangement of the ions in a crystal These new ways of thinking and of investigating supplement in a welcome way the older ideas of cond., and of the osmotic and electromotive behavior of electrolytes. Quantitatively, however, we can treat only the limiting simplest systems—the most highly dild. solns. of strong electrolytes and the weakest ionized solns. of weak electrolytes; in our judgment of the complicated systems of strong electrolyte solns. and melts we depend largely upon our fancy......"
W. C. Ebaugh

The question of strong electrolytes. A. Gyemant. *Physik. Z.* **29,** 289-93(1928).—Measurements of the cond. of strong electrolytes in very poorly conducting org. solvents are in agreement with the assumption of incomplete dissocn. of strong electrolytes. Equations derived on the basis of this assumption satisfy the exptl data. In such solns. the Wien effect, *i. e.*, the dependence of the cond. on the field strength (cf. *C. A.* **22,** 3084) was demonstrated. However, the cond. transverse to the field strength was const. It is concluded that undissocd. ion pairs are only loosely combined and can contribute to the total cond. when the field strength is large.
E. R. Smith

The question of strong electrolytes and the dependence of the conductivity on potential. Georg Joos. *Physik Z.* **29,** 570(1928).—J. comments briefly on the work of A. Gyemant in relation to the Wien effect (cf. preceding abstract). R. L. H.

Dielectric constant of aqueous solutions of sodium chloride. Arthur Bramley. Bartol Foundation. *J. Franklin Inst.* **205,** 649-58(1928).—An interferometer method, depending on electrostriction produced in a soln. by an applied elec. field, has been used to det. the dielec. const. This obviates the difficulty of measuring the capacity of a cell with an appreciable cond. According to Debye and Hückel, $D = D_0 (1 - \alpha y)$, where D_0 is the dielec. const. of the solvent, α a const. depending on the types of ions present in the soln. and y the concn. of the soln. in moles per l. D. and H. found α = 6.6 for NaCl. B. finds for small concns. $\alpha = 7.85$. At higher concns. $D^2 = D_0^2 (1 - \alpha' y)$ and $\alpha' = 15.7$. A max. error of 4% is claimed. The theoretical background of the method is discussed.
W. T. Richards

Determination of partition coefficients for ions. Ernst Allemann. Inst. für physikal. Chem. der E. T. H. Zürich. *Z. Elektrochem.* **34,** 373-87(1928).—The phase-boundary potential between an aq. soln. of an electrolyte, MR, and a soln. of the same electrolyte in liquid A was measured by means of the cell

N HgCl electrode | KCl aq. | MR in H_2O | MR in A | KCl in A | KCl aq. | N HgCl electrode

arranged in app. so that the distance that the current had to travel through the relatively poorly conducting phases with liquid A was short. Data are given for 85 phase-boundary potentials for 50 inorg. and org. salts in H_2O and in amyl alc., butyl alc. or furfural. When the electrolyte is uni-univalent, the potential between the 2 liquid phases can be calcd. from sp. partition coeffs. for the ions. A number of such sp. ion partition coeffs. between butyl alc.-satd. H_2O and H_2O-satd. butyl alc. are given. A method of detg. the relation between concn. and boundary potential is described.

F. L. Browne

The amphoteric character of cadmium hydroxide. J. Piater. Univ. Leipzig. *Z. anorg. allgem. Chem.* **174**, 321–41(1928).—The soly. of $Cd(OH)_2$ in H_2O and NaOH solns. at 25° has been detd. in order to ascertain if it possesses acid properties. By this means, the weakly acid character of $Cd(OH)_2$ has been proved. The solubilities of one CdO, and three $Cd(OH)_2$ prepns. were detd. by cond. measurements.

Preparation	Soly. at 25°
CdO	1.70×10^{-5} mols./l.
$Cd(OH)_2$, cryst., 1% alkali	1.30×10^{-5} mols./l.
$Cd(OH)_2$, from NH_3	1.14×10^{-5} mols./l.
$Cd(OH)_2$ (pptd. from dil. soln.)	
directly after prepn.	1.11×10^{-5} mols./l.
after 9 months	1.18×10^{-5} mols./l.

J. H. Perry

Molecular condition of salts in solution. H. Ulich and E. J. Birr. Univ. Rostock. *Z. angew. Chem.* **41**, 443–6, 467–72(1928).—A discussion of the characteristics of aq. and non-aq. solns. of salts. Among the solvents considered are H_2O, MeOH, EtOH, Me_2CO, formaldehyde, MeCN, epichlorohydrin and C_5H_5N, and the conditions represented by infinite diln., finite diln. and concd. solns. are studied. H. Stoertz

The titrimetric determination of acids and bases in various solvents. K. Linderstrøm-Lang. *Dansk. Tids. Farm.* **2**, No. 8, 201–32(1928); cf. *C. A.* **22**, 1115.—Brønsted's (*C. A.* **17**, 3821) conception of acids and bases was taken as a basis for L.'s investigation. Other references suggested are: "Theorie der alkalimetrischen und acidimetrischen Titrierungen" by N. Bjerrum, and *Fys. Tids.* **16**(1917–18). (I) Conception of acid and base, cf. Brønsted. Substances that in various solvents are capable of giving off H^+ are termed acids, those capable of adding H^+ bases. Equil. equation between bases (B) and acids (A), becomes $B + H^+ \rightleftharpoons A$. Substances capable of giving off or taking on H^+ are ampholytes, *e. g.* $H_2PO_4^- + H^+ \rightleftharpoons H_3PO_4$; $HPO_4^{--} + H^+ \rightleftharpoons H_2PO_4^-$; the $H_2PO_4^-$ is thus an ampholyte. Other examples are given. (II) Equil. equation in aq. soln. (AcOH considered). $p_H = p_A - \log (C_{AcOH}/C_{AcO^-})$, where p_A represents the acid's strength exponent. This expression is readily expanded to $p_H = P - \log C_A/C_B$ (5) where P is the acid-base exponent, a term dependent on the nature (strength) of the corresponding acids and bases but not on their concn. C_A or C_B or on p_H. Equation (5) is expressed graphically with p_H = abscissa and C_A/C_B = ordinate. At the point where $C_A = C_B$, $P = p_H$ (where acid and base are present in equil. amts.). The curve also shows that a base and its corresponding acid have the same acid-base exponent, this being higher the stronger the base and weaker the acid. A table is given showing the value of P for a no. of corresponding acids and bases. Ampholytes also enter in, and appear in 2 diff. equations: one where ampholyte appears as an acid and one where it appears as base, *e. g.*, P_A and P_B. A table shows values of P_A and P_B for a no. of ampholytes. (III) Problem of concn p_H. It is not known how molecules exist in soln., *e. g.*, NH_3 probably forms a series of complexes: $NH_3.H_2O$; $NH_3.2H_2O$, etc. H^+ is unable to exist in the free state, but in H_2O it exists as H_3O^+, associated with H_2O; $H_3O^+.H_2O$; $H_3O^+.2H_2O$, etc.; similarly for other solvents. From thermodynamic reasoning L. suggests stating concn. as $C_{MA} = (C_H)$; C_B and C_A = total concn. of H^+, bases and acids in all the forms of complexes in which they appear in pure un-ionized solvents, *viz.*, NH_3 in H_2O = $C_B = C_{NH_3} + C_{NH_3 \cdot H_2O} + \ldots$ The expression $p_H = -\log C_H$ is considered inaccurate, whence p_H is defined as $p_H = (E - 0.3380)/0.0577$ (9), where E is the potential of the cell Pt, H_2 soln. | KCl | 0.1 N KCl | Hg_2Cl_2, Hg (1) (18° C. – 760 mm.). (IV) Equil. equation in various solvents. Equation (5) holds, since P depends on the nature of acid and base as well as solvent, but not on C_A, C_B and C_{MA}. A table showing values of P for H_2O, aq. MeOH and EtOH is given. (V) The special relation of the solvent (M). Solvent M is considered an ampholyte. Then $C_{MA} = C_{MH^+} + C_{H^+2M}$, etc

$C_{MB} = C_{M^-H^+} + C_{2M^-H^+}$, etc., or for H_2O, $C_{MA} = C_{H_3O^+} +$, etc. $C_{MB} = C_{OH^-} + C_{OH^-H_2O}$, etc. The problem is to formulate an equil. equation similar to (5). The different complexes are considered in equil. or $C_{MH^+}.C_M = K_1.C_{H^+2M}$, etc., for processes $MH^+ + M = H^+2M$; $H^+2M + M = H^+3M$, etc., but C_M may be considered const. or $C_{MH^+}/C_{2MH^+} = K_1 \cdot C_{2MH^+}/C_{3MH^+} = K_2$, or for dil. solns. where the concn. of the complexes is const. $C_{MH^+} = K_1'(C_{MH^+} + C_{2MH^+} + \ldots) = K_1'.C_{MA}$. Substituting in the equil. equation for M's base function $p_H = P_B - \log C_{MH^+}/C_M$, C_M = const. and $C_{MH^+} = K_1'.C_{MA}$, one obtains $p_H = L_B - \log C_{MA}$ (16) in which L_B is a new const., the M's base exponent. But $p_H = -\log C_H = -\log C_{MA}$ or $L_{B(H_2O)} = 0$. In similar fashion it can be shown that $p_H = L_A + \log C_{MB}$ (17), where L_A is M's acid exponent. Subtracting (16) from (17) $L_B - L_A = \log C_{MA} + \log C_{MB} = \log (C_{MA}.C_{MB})$, which states that the difference between L_B and L_A is the log of the dissocn. const. A table showing values of L_B and L_A for different solvents is given. (VI). The elements of the titration theory. In this part the author develops equations for titrating a base with an acid, error from medium, titrand (base) and titrator (acid), and corresponding equation for titrating acids with bases. For titrating a base with an acid m_B and m_A = g. equiv. of base or acid in solvent. V = vol. in liters and C_B or C_A g equiv. per liter; thus $m_B = VC_B$; $m_A = VC_A$, TA = titrating acid. TA is dissolved in pure solvent to a known concn.; the titrand medium contains Q_B g. equiv. base. Q_{TA} = g. equiv. acid used to reach the end point as detd. by p_H value. The no. of H^+ which TA has given off must be the no. H^+B has taken on ± no of H^+ medium (M) has required or $TH = m_A + V(C_{MA} - C_{MB})$ (20) or from (5) $Q_B = m_A + m_B = m_A(1 - 10^{pH'-P})$ (21) and from (16) and (17) $C_{MA} = 10^{L_B - pH'}$, $C_{MB} = 10^{pH'-L_A}$. $TH^+ = [Q_B/(1 + 10^{pH'-P})] + V(10^{L_B-pH'} - 10^{pH'-L_A})$ (22). If TA is a corresponding acid to the medium then $Q_{TA} = TH^+ = Q_{MA}$. Substituting Q_{TA} in (22) gives equation (23). If, however, TA is a different acid with an acid-base exponent P_T, one obtains $[Q_{TA}/(1 + 10^{P_T - pH'})] = [Q_B/(1 + 10^{pH'-P})] + V(10^{L_B-pH'} - 10^{pH'-L_A})$ (25). Equations 23 and 25 may readily be expanded so as to apply to mixts. of bases. From (25) it will be seen that $Q_B = Q_{TA}$ when $V(10^{L_B-pH'} - 10^{pH'-L_A})$ (error of medium), $10^{pH'-P}$ (titrand error) and $10^{P_T-pH'}$ (titrator error) disappear. The author now goes on to give a math. treatment of these different errors, of the uncertainties of the titration and of titrations of mixts. of bases, also corresponding considerations of titrating acids with bases. A discussion of indicators is also given, together with a considerable no. of examples. Part (VII) conclusion. A brief discussion of the results obtained in the examples given in (VI). O. A. NELSON

The electrometric determination of the concentration of calcium ions by means of electrodes of the third class. M. H. CORTEN AND I. ESTERMANN. Hamburg Univ. *Z. physik. Chem.* **136,** 228–30(1928).—Both of the electrodes $Ag \mid Ag_2C_2O_4 \mid CaC_2O_4 \mid Ca^{++}$ and $Zn \mid ZnC_2O_4 \mid CaC_2O_4 \mid Ca^{++}$ were found to give potentials accurate and reproducible to 0.001 v. The construction of such electrodes is described. Their application to the measurement of Ca^{++} concn in blood serum will be described later. R. L. D.

New practical application of the quinhydrone electrode, of new indicators and of the de Wulff leaf colorimeter to spectrophotometry. GEORGES HUGONIN. *Chimie & industrie* **Special No.,** 732–74(April, 1928).—A crit. review, with bibliography of 66 references. A. PAPINEAU-COUTURE

The principles of the electrometric determination of hydrogen-ion concentration and their practical execution. R. SCHMIDT. *Kl. Mitt. Ver. Wasserversorg. Abwässerbeseitig.* **3,** 269–78; *Chem. Zentr.* **1927,** II, 2328.—A general, comprehensive description of electrometric methods for measuring the reaction of a liquid, with special reference to quinhydrone electrodes. Tables show the p_H values for temps. from 18° to 24° for different millivolt readings. C. C. DAVIS

Determination of hydrogen-ion concentrations in phosphate and borate mixtures by means of the quinhydrone electrodes. EINAR BIILMANN, ANDREAS KLIT AND TOIVO SWAETICHIN. *Biochem. J.* **22,** 845–54(1928).—The quinhydrone electrode gives correct p_H values in phosphate mixts. up to 7.73; the quinoquinhydrone electrode, up to p_H 7.38. The hydroquinhydrone electrode gave stable potentials but too low p_H values. BENJAMIN HARROW

A rapid method for determining colorimetrically the p_H of small amounts of solutions. OSCAR W. RICHARDS. *Science* **68,** 185(1928).—A description is given for the prepn. and use of a pipet designed to insure uniform samples for color comparisons. Covering the spotting plate with a thin layer of pure white vaseline made the drops stand up like beads. W. W. STIFLER

The stratification phenomenon in electrodialysis as an electrophoretic occurrence. F. BLANK AND E. VALKÓ. *Biochem. Z.* **195,** 220–7(1928).—The appearance of a colloid-

free layer in electrodialysis is shown to be due to combined effect of electrophoretic and hydrostatic forces. S. MORGULIS

Dialysis. III. Temperature coefficient of dialysis. H. BRINTZINGER AND B. TROEMER. Jena Univ. *Z. anorg. allgem. Chem.* **172,** 426–8(1928).—When the temp. and sp. surface are const. and when the uniformity of the inner liquid and the zero concn. of the outer liquid are preserved, then dialysis proceeds according to the law $c_t = c_i e^{-\lambda t}$, where λ is a typical const. dependent upon the membrane, the magnitude of the sp. surface, the concn., the presence of other diffusible and non-diffusible substances and upon the temp. B. and T. detd. λ for a large no. of substances and found a connection between λ and the magnitude of the elec. field intensity with the surface of the ions concerned. They also detd. the change in λ of electrolytes with change in concn. and in the presence of other electrolytes. Apparently, the difference in chem. and phys. bound water is reflected in the magnitude of λ. The dialysis coeffs. (for $F = 1$) of equimolar solns. were detd. at different temps., the temp. curve for λ being obtained. The equation holding is $\lambda_{T'} = \lambda_T[1 + \alpha(T' - T)]$, where α is a typical coeff. of every substance. Exptl. data, etc., will be published later. S. L. B. E.

Surface tension and solvation in salt solution. P. P. KOSAKEVICH. Chem. Lab., Inst. Volkswirtschaft, Charkow. *Z. physik. Chem.* **136,** 195–207(1928).—The capillary-rise method was used to study the effect of I, Br, Cl and Li, Na and K ions on the surface tension of pyridine, $(CH_3)_2CO$, CH_3OH and HCOOH. With all these solvents the capillary activity of the ions was in the order I > Br > Cl and Li > Na > K. With the cations this order is the reverse of that observed for H_2O solns., but the order for the anions is the same as for H_2O. The order I > Br > Cl also held for C_2H_5OH-H_2O mixts. when the C_2H_5OH concn. was greater than 0.2 *N*. From the relationship between capillary activity of the salts of these ions and the compn. of the alc.-H_2O mixts. was calcd. the order of the distribution coeffs. of these salts between alc. (solvation) and H_2O (hydration). The lyotropic series I > Br > Cl, observed for non-aq. solvents, was attributed to decreasing solvation. R. L. DODGE

The osmotic pressures of concentrated solutions. WILDER D. BANCROFT AND HERBERT L. DAVIS. Cornell Univ. *J. Phys. Chem.* **32,** 1(1928); cf. *C. A.* **22,** 527.—An enlargement of the ideas in the article referred to, emphasizing the doctrine of relating osmotic pressure to the *volumes of the solvent in soln.* B. and D. derive 2 equations (1) $PV_m = RT \ln (p_0/p_1)$ and (2) $PV_1 = RT\left(\frac{N}{n}\right) \ln (p_0/p_1)$. P is osmotic pressure; p_0 and p_1 are vapor pressures of solvent and soln., resp.; V_m is the g.-mol. vol. of the *solvent in soln.* (assuming the mol. wt. is that in the vapor phase); V_1 is the vol. in soln. of the mass of solvent contg. 1 mol. of solute; N and n refer to solvent and solute, resp. They discuss the validity of equations of the gas-law type to represent osmotic phenomena and point out that the absence of any function of the heat of diln., a work term which cannot be evaluated, prevents these equations from ever being exact. The relations between equations (1) and (2) and mol. wt. calcn., b. p. and f. p. changes are given. Equation (1) is used to det. vols. in soln. and conversely from density and vapor pressure data, osmotic pressures are calcd. It is also pointed out that equations of the type of that used by van der Waals for gases may be well applied to solns. R. E. GIBSON

Osmotic pressures of concentrated solutions. J. H. HILDEBRAND. *J. Phys. Chem.* **32,** 1086–8(1928).—A criticism of Bancroft and Davis' recent papers (*C. A.* **22,** 527; preceding abstract) on osmotic pressures of concd. solns., particularly as to their misinterpretation of Raoult's and van't Hoff's equations. G. L. C.

Composition of bone. V. Some properties of calcium citrate. M. J. SHEAR AND BENJAMIN KRAMER. Jewish Hosp., Brooklyn, N. Y. *J. Biol. Chem.* **79,** 161–75 (1928).—Cond. titration of NaCl with Na citrate gives normal results in good agreement with calcd. values. Abnormal results are obtained with $CaCl_2$; an ionic reaction occurs which results in a decrease in the no. of ions, but with further addn. of Na citrate fewer and fewer ions are removed from soln. until finally no further diminution occurs and the resistance then decreases in agreement with the calcd. values. These results are direct evidence for the binding of Ca ions by Na citrate in some kind of sol. complex. A. P. LOTHROP

Liquid binary mixtures and so-called molecular compounds. GEORG WEISSENBERGER. *Metallbörse* **17,** 708; *Chem. Zentr.* **1927,** II, 2144.—The vapor-pressure curve of a binary liquid mixt. is, as already shown in extensive investigations of W. (*C. A.* **21,** 1215), in no way a straight line, the curve showing important deviations. Positive deviations of the vapor pressure curve of chlorotetralin-acetone occur when both kinds of mols. exercise a repulsive action against each other, whereas negative deviations

are found where the mols. attract each other, as with Cl_2CHCO_2H-Et_2O. If this attraction is great enough, solid mol. compds. are formed. This *transition between mixts. and compds.* manifests itself in other phys. properties. C. C. DAVIS

The permeability of membranes. V. The diffusion of nonelectrolytes through the dried collodion membranes. A. A. WEECH AND L. MICHAELIS. Johns Hopkins Univ. and Marine Biol. Lab., Woods Hole, Mass. *J. Gen. Physiol.* **12**, 55–81(1928); cf. *C. A.* **22**, 1516.—$(CH_3)_2CO$ and urea pass through a dried collodion membrane much more rapidly than does glycerol; glycerol diffuses much faster than glucose. The rate of diffusion varies directly with the difference in concn. of the solns. sepd. by the membrane. The presence of glycerol on the two sides of the membrane does not appreciably affect the rate of diffusion of $(CH_3)_2CO$. Expts. showed that the membrane channels may gradually become clogged with glucose mols. so that the diffusion rate decreases from day to day until the stationary gradient is reached. The collodion membrane is conceived as a sieve with pores of about mol. size. Differences in diffusion rate are probably due to differences in size of the diffusing mols., the relatively large glycerol and glucose mols. being unable to pass through the smaller pores available for the passage of urea and $(CH_3)_2CO$ mols. In attempting to correlate the ratio between the diffusion rates of 2 different substances with the concn. potential, *CoP* (cf. Michaelis, Ellsworth and Weech, *C. A.* **21**, 3008; Michaelis and Perlzweig, *C. A.* **21**, 2837), given by the same membrane, the results were: (1) the acetone-glycerol ratio shows no correspondence; (2) the acetone-glucose ratio suggests a relation; (3) the glycerol-glucose ratio shows a definite correspondence, the higher ratios being obtained with membranes giving high *CoP* values. An explanation of the facts is proposed which postulates an adhesion or adsorption between the anions of electrolytes and the surface of the pore channels, whereas in the case of diffusing nonelectrolytes there are no adhesive forces, the rate of passage depending upon the no. of pores large enough to transmit the mols. The no. of pores which will permit the passage of acetone and glycerol is too small to fall in the range of potential variation. The no. of pores which will transmit glycerol and glucose, however, is included in the range where there is an evident relation between the diffusion rate ratios and the *CoP* value. C. H. R.

The kinetics of nitrous acid. I. Introduction and review. II. Pertinent experiments. E. ABEL AND H. SCHMID. *Z. physik. Chem.* **132**, 55–77(1928).—The reaction mechanism of the decompn. of HNO_2 has been studied as being the controlling factor in the rate of the reaction between N_2O_4 and H_2O. Unless supersatn. of the soln. with NO is not avoided, the rate of disappearance of HNO_2 is not a measure of the rate of the reaction: $3HNO_2 \longrightarrow H^+ + NO_3^- + 2NO + H_2O$. **III. Kinetics of the decomposition of nitrous acid.** *Ibid* **134**, 279–300.—The app. and technic are described for the study of the decompn. of HNO_2 according to the equation: $3HNO_2 \longrightarrow H^+ + NO_3^- + 2NO + H_2O$. The reverse reaction has not been studied. The rate of the forward reaction is proportional to the 4th power of the undissocd. acid, and inversely proportional to (NO concn.)^2. The rate of decompn. is also inversely proportional to the square of the partial pressure of NO. The reaction rate coeff. is an almost linear function of the ionic concn. for which math. expressions are given. If SO_4 ions are present, the reaction mechanism is greatly complicated. The decompn. reaction involves the hydrolysis of N_2O_4 as a side reaction, the rate of which is expressed by the equation: $-d(N_2O_4)/dt = 2 \times 10^4 P_{N_2O_4}$, where $P_{N_2O_4}$ is the partial pressure of N_2O_4. **IV. Kinetics of the formation of nitrous acid from nitric acid and nitric oxide.** E. ABEL, H. SCHMID AND S. BABAD. *Ibid* **136**, 135–45.—The rate of reaction, according to the gross equation: $HNO_3 + 2NO + H_2O \longrightarrow 3HNO_2$ is proportional to the H-ion concn., the NO_3-ion and the HNO_2 concns. HNO_2 is an autocatalyzer. The rate is independent of the partial pressure of NO, and decreases slightly with increasing ion concn. Sulfate ions are retardant to the reaction. The formation of HNO_2 occurs in two steps: (1) $H^+ + NO_3^- + HNO_2 \longrightarrow N_2O_4 + H_2O$; and (2) $N_2O_4 + 2\,NO + 2\,H_2O \longrightarrow 4\,HNO_2$, and (1) dets. the rate of the gross reaction. J. H. PERRY

Nitration velocities. F. H. COHEN. Univ. Amsterdam. *Verslag. Akad. Wetenschappen Amsterdam* **37**, 593–601(1928); cf. Wibaut, *C. A.* **10**, 184.—Aromatic substances were nitrated in Ac_2O. The analysis was made by pouring a known quantity of mixt. into KOH of 1.3 d., removing nitrobenzene by C_6H_6 extn. and detg. KNO_3 by Devarda distn. HNO_2 was detd. colorimetrically by the Griess-Ilosvay method, the HNO_2 being neutralized with solid AcONa. From expts. at 25° (C_6H_6 in Ac_2O) k from $2.3025/t(C_0 - C_0')\log(C_0'C/C_0C')$ (bimol.) was const. up to 51.6% reaction (HNO_3 C_0 = 0.6682, C_6H_6 C_0' = 0.4385, HNO_2 = 0.0011, t = 574 min.) and equal to 0.00232. On adding 8 mg. urea to take HNO_2 away, this k for approx. the same C

values decreased to 0.00140 and 37.2% reaction yield in 546 min. The nitrous acid is a catalyzer. The question of side reactions of HNO_3 with the solvent is discussed; no definite results were obtained although it was found that the titer of HNO_3 in Ac_2O decreases from 0.72 to 0.29 in 1811 min. more or less linearly. The reaction of HNO_3 and Ac_2O is considerable, almost to explosivity, catalyzed by a few drops strong H_2SO_4. At 18° was found k = 0.00128 for the benzene nitration reaction, a temp. coeff. of 2.3; at 0° and 40° the "const." was irregular. No nitration was found in glacial AcOH soln. The HNO_3 content was unchanged after 24 hrs.; addns. of anhydride did not change this. B. J. C. VAN DER HOEVEN

Group theory of homopolar chemical combination. W. HEITLER. *Z. Physik* **47**, 835–58(1928).—Mathematical. An extension of the theory of Heitler and London (*C. A.* **21**, 3542). B. C. A.

The activity coefficients of sodium and potassium hydroxides in their corresponding chloride solutions at high constant total molality. HERBERT S. HARNED AND JOHN McA. HARRIS, JR. Univ. of Penna. *J. Am. Chem. Soc.* **50**, 2633–7(1928). Measurements at 25° of the e.m.f. of the cells H_2 | KOH (m_1), KCl (m_2) | K_xHg | KOH (m_0) | H_2, wherein ($m_1 + m_2$) is const. at 3.5 molal, and of the cells H_2 | NaOH (m_1), NaCl (m_2) | Na_xHg | NaOH (m_0) | H_2, wherein ($m_1 + m_2$) is const. at either 3.5 or 5 molal, have been made, and the activity coefficients of the hydroxides in the chloride solns. calcd. The variations of activity coefficients with total molalities in the several cases are not strictly linear, although the discrepancies are not large. WILLIAM E. VAUGHAN

The rate of reaction of liquid and gaseous zinc with carbon monoxide. RUSSELL W. MILLAR. *J. Am. Chem. Soc.* **50**, 2707–9(1928).—A series of distns. of Zn in CO at temps. near 700° showed no free C when SiO_2 formed the walls of the reaction chamber. If firebrick contg. Fe was used also in the reaction vessel C sepd., but if no Fe was in the firebrick no C was obtained. The reduction of CO by Zn at 600–700° is extremely slow in the absence of a catalyst—probably slower than the decompn. of CO into CO_2 and C under the same conditions. But Zn reduces CO_2 rapidly at the given temps. The production of ZnO in a Zn-condenser is due then to the oxidation of Zn by CO_2 or H_2O vapor. Pure CO is an excellent atmosphere in which to distil Zn, provided the walls of the vessel are free from Fe. W. C. EBAUGH

Problems of energy transfer in chemical reaction kinetics. C. N. HINSHELWOOD. *Physik. Z.* **29**, 556–8(1928).—In bimolecular gaseous reactions the no. of mols. reacting per sec. is, almost without exception, equal in magnitude to the no. of mols. colliding per sec. multiplied by $e^{-E/RT}$, where E is the heat of activation. In quasi-monomol. reactions the time interval of reaction of a mol. is greater than the mean interval between collisions; hence an activated mol. may be deactivated before it has opportunity to react. k is then equal to $N \times f(E) \times X$, where N is the total no. of mols., $f(E)$ is the fraction of mols. having sufficient energy to react and X is a probability coeff. At low pressures such reactions no longer show quasi-monomolecular behavior, k decreasing with pressure. A quantum-theory treatment of mol. sizes is suggested in connection with the problem of the decompositon of N_2O_5, which under certain condition shows a greater reaction rate than the max. calcd. rate of activation. Aspects of other problems in chem. kinetics are briefly mentioned. R. L. HERSHEY

Influence of electrolytes on the velocity of cataphoresis and relations between the electrokinetic potential and electromotive potential of gold. NATHANIEL THON. *Compt. rend.* **187**, 119–22(1928).—For the same system of contact the electromotive potential φ and the electrokinetic potential ζ represent two different magnitudes. Some electrolytes cause first an increase of negative potential ζ. Some reduce ζ from the beginning. The first type is obtained only with salts having univalent cations. The inhibiting effect increases with the diminution of the soln. pressure of the cation: Example: $ZnSO_4$, $NiSO_4$, $CuSO_4$, $Ca(NO_3)_2$, $Pb(NO_3)_2$. L. D. R.

The accuracy and practical execution of the quantitative kinetic analysis for bimolecular reactions. LENNART SMITH AND J. LINDBERG. *Ber.* **61B**, 1709–17(1928). The equation describing the reaction is given and its mathematical significance is explained. Calcd. and observed values are given for mixts. of glycerol-α-monochlorohydrin. Two methods of measuring percentage error are used which check. Data are given on the accuracy of the calcn. of this kinetic mechanism during reaction. RAYMOND H. LAMBERT

Phosgene equilibrium. R. NITZSCHMANN. *Metallbörse* **17**, 1601–2; *Chem. Zentr.* **1927**, II, 1513.—A theoretical derivation of the conditions for the formation of $COCl_2$ according to the equation: $CO + Cl_2 \longrightarrow COCl_2 + 24{,}600$ cal. The const. K is 2422 × 10^{-14} at 300° abs., 1526 × 10^{-3} at 700°, 1700 × 10^{-2} at 800°, 11,334 × 10^{-1} at 900°, 5256 × 10^{-1} at 1000°. Tabulated data are given for the range of 95

99%. the temps. −15.34° to 22.43° and P = 1–2 at. on the liquefaction stage, the end concn. and the tension of initial liquefaction. J. S. REICHERT

The law of electrolyte equilibrium and conductivity. K. JABLCZYNSKI. *Roczniki Chem.* **8,** 22–30(1928); cf. *C. A.* **16,** 3021; **18,** 3513.—The dissocn. consts. K of KCl, KBr, KI, KCN, RbCl, RbBr, NH_4I and NH_4CNS were calcd. from the cond. according to the Jablczynski and Wisniewski equation for mass action. They are practically const. and agree well with the K calcd. from ebullioscopic data. K increases in the order Cl, Br, I, in accordance with the increasing atomic radius. The K of NaCl and LiCl the cations of which are hydrated was equal to that of KCl only after extrapolation: $K_\alpha = K + A.N^{1/3}$. The same K was calcd. from the f. p. It is practically the same for the 3 chlorides, the radii of N_α, Li and K being practically equal. Kohlrausch's equation does not give const. values. With the aid of his equil. equation J. calcs.: $\lambda_\alpha = \lambda + d^{1/3}.N^{1/3}$ (1), where $d = 1/\lambda_\alpha^{1/3}K$. d is const., while a in Kohlrausch's equation decreases inversely with the concn. (1) is preferable to the equation of Debye and Huckel since it gives very satisfactory agreement up to concns. of 3 N, while the equation of D. and H does not obtain above 0.01 N.

MARY JACOBSEN

Equilibrium of solutions of barium chloride and lead chloride in hydrochloric acid and water. P. VOLKOV. *Ann. inst. anal. phys. chim.* (*Leningrad*) **3,** 704–24; *Chem. Zentr.* **1927,** II, 2702.—For the *purification of $BaCl_2$-$RaCl_2$ solns. contg. $PbCl_2$*, a knowledge of the contemporary solv. of $PbCl_2$ and $BaCl_2$ in HCl and water should be of value. The following exptl. data give the no. of g. of HCl in 1000 g. of water and the no. of g. of $PbCl_2$ per 1000 g. of water which are sol. in the HCl soln.: *at* 25°: 0, 10.8; 8.68, 2.37; 38.50, 1.29; 126.6, 2.55; 249.7, 10.10; 422.0, 42.85; 553.4, 61.00; *at* 0°: 0, 6.25, 8.36, 0.771; 51.01, 0.410; 175.15, 2.275; 383.7, 29.97; 574.0, 56.65. The initial decrease in the solv. of $PbCl_2$ with increasing concn. of HCl is attributed to the influence of the common ion, and the subsequent increase in the solv. of $PbCl_2$ is attributed to the formation of complexes. The solv. of $BaCl_2$ in HCl has already been measured by Eliseev (*C. A.* **21,** 3820). The solv of $PbCl_2$ is greatly diminished at first by the addn. of $BaCl_2$ but with large addns. of $BaCl_2$, it is increased. The following data give the no. of g of $BaCl_2$ per 1000 g. of water and the no. of g. of $PbCl_2$ per 1000 g. of water which are sol in the $BaCl_2$ soln.: *at* 25°: 50.8, 1.98; 103.6, 1.83; 230.0, 3.33; 338.8, 6.59; *at* 0°. 51.6, 0.635; 124.2, 0.627 The triple point ($BaCl_2.2H_2O$ and $PbCl_2$ in the ppt) lies at $BaCl_2$ 375.5 and $PbCl_2$ 8.7 at 25° and at $BaCl_2$ 310.5 and $PbCl_2$ 2.5 at 0°. The soly. of $BaCl_2$ is only slightly increased by the addn. of $PbCl_2$. By the addn of HCl to a soln. satd simultaneous with $BaCl_2.2H_2O$ and $PbCl_2$, the soly. of $BaCl_2$ is reduced and that of $PbCl_2$ increased Thus at 25° the following data were obtained: HCl (g per 1000 g. water) 38.6, 101.5, 148.9, 194.9, 301.99, 553.4; $BaCl_2$ (g per 1000 g water) 252.1, 95.05, 32.1, 9.6, 0.9, 0.00; $PbCl_2$ (g. per 1000 g. water) 6.05, 4.05, 4.02, 5.81, 17.85, 61.00. The effect of HCl at 0° is similar Since from the triple soln." only $BaCl_2$ is pptd. by HCl, the removal of $PbCl_2$ from radioactive $BaCl_2$ can be carried out. C. C. DAVIS

The equilibrium $2K_3Fe(CN)_6 + 2KI \rightleftharpoons 2K_4Fe(CN)_6 + I_2$ in aqueous potassium chloride solutions. VICTOR K. LA MER AND KARL SANDVED. Columbia Univ. *J. Am. Chem. Soc.* **50,** 2650–65(1928).—The equil. state for the reaction $2Fe(CN)_6^{---} + 3I^- \rightleftharpoons 2Fe(CN)_6$ IV $+ I_3^-$ has been studied analytically for the K salts in pure H_2O as well as in aq. KCl solns. as solvents. With H_2O as solvent the value of $K_{eq.}$ changes 35% when the concn. of KI is increased from 0.15 M to 0.20 M, but the corresponding change is less than 2% in the presence of 1.0 M KCl. The data confirm the principle that the law of mass action holds for ionic systems when a sufficient excess of neutral salts is present to maintain a const. elec. environment, although this law fails completely in absence of excess of neutral salts. The inadequacy of the principle of ionic strength for high-valence ions is also evident in this system. The equil. const. in the absence of salt effects has been computed from e. m. f. data and found to be 0.199×10^{-3}. Addns. of HCl up to a p_H value of about 3.5 is without influence upon $K_{eq.}$, but is of marked influence in more acid ranges. R. H. LOMBARD

Systems with recurrent fusion curves. I. A. SMITS. Univ. Amsterdam. *Z. physik. Chem.* **135,** 63–72(1928).—By starting with van der Waals' equation for the phase equil. between 2 coexisting phases, by thermodynamic reasoning an equation for the equil between 3 phases, gas, liquid, solid, at the vapor pressure is set up in which the temp. coeff. of compn. of the liquid phase, x_L, is connected with the vol. change and heat evolution. Examn. of this equation shows that ordinarily $T(dx_L/dT)$ is positive, that is, the fusion curve on the T-x diagram has a positive slope. If the solid phase sepg at lower temp. is a hydrate which at some higher temp. changes to the anhyd

salt while the salt mols. in soln. remain mostly hydrated, a condition arises in which soln. of the anhyd. salt in the satd. soln. is accompanied by a strongly exothermal chem. reaction. Under such circumstances $T(dx_L/dT)$ may become negative and the fusion curve take a negative slope (recurrent curve). If as the temp. increases further the dissolved salt mols. become less hydrated, the fusion curve may bend back through a point with a vertical tangent and become positively sloped once more, continuing until the m. p. of the pure anhyd. salt is reached. A recurrent fusion curve may also arise from the close approach of the fusion curve to the critical curve, in which case a crit. end point is reached, that is, the fusion curve runs into the vapor curve. At a still higher temp. a sep. branch of the fusion curve emerges again from the vapor curve and continues until it meets the m. p. of the solid. Such a case has been observed in the system ether–anthraquinone. Theoretically a third case should be possible in which the fusion curve swings from a negative slope caused by equil. between anhyd. solid phase and liquid phase contg. dissolved hydrate, passes through a vertical tangent to attain a positive slope, and then again swings back through a second vertical tangent to a negative slope caused by proximity to the crit. curve, finally reaching a critical end point. **II.** (1) **The system water sodium selenate.** A. SMITS AND W. M. MAZEE. *Ibid* 73–6.—The *T-x* diagram for the system H_2O–Na_2SeO_4 is given. Below 30.3° the solid phase is $Na_2SeO_4.10H_2O$ from the eutectic at 1 mol. % Na_2SeO_4 to 7.5 mol. %, with the fusion curve sloped positively. Above 30.3° the solid phase is Na_2SeO_4 and the fusion curve has a negative slope. At about 170° and 6.25 mol. % Na_2SeO_4 there is a vertical tangent to the fusion curve which then slopes in the positive direction until it reaches the m. p. of Na_2SeO_4 at 777°. **II.** (2) **The system water–sodium sulfate.** A. SMITS AND J. P. WHITE. *Ibid* 77–8.—The solid phase below 32.4° from the eutectic to 6 mol. % Na_2SO_4 is the hydrate $Na_2SO_4.10H_2O$ and the fusion curve slopes positively. Above 32.4° the solid phase is Na_2SO_4 and the fusion curve slopes negatively, passes through a vertical tangent at about 140° and 4.75 mol. % Na_2SO_4, and at 235° reaches a transition temp. at which the rhombic form of Na_2SO_4 changes to the monoclinic. Above 235° the fusion curve has a negative slope again until it reaches a critical end point at 365°. The change of crystal form probably prevents the exptl. realization of the theoretically interesting case of a continuous fusion curve with 2 vertical tangents. **III.** (3) **The system water-magnesium sulfate.** A. SMITS, J. RINSE AND L. H. LOUWE KOOYMANS *Ibid* 78–84.—The hydrate $MgSO_4.12H_2O$ is stable from the eutectic to about 2°, $MgSO_4.7H_2O$ from 2° to 48°, and $MgSO_4.6H_2O$ from 48° to 70°, all with fusion curves sloping positively. Above 70° and 8 mol. % $MgSO_4$ the fusion curve for $MgSO_4.H_2O$ slopes sharply to the left and then at about 200° and about 0.1 mol. % $MgSO_4$ it bends back nearly vertical, but reaches a crit. end point at 265°. F. L. BROWNE

Theory of sorption. II. Mechanism of heterogeneous catalysis. O. SCHMIDT. *Z. physik Chem.* **133,** 263–303(1928).—The sorption at 1 atm. pressure and at const temp. between 0° and 150° of gases for which the mol. diam. is less than the mean diam. of the pores of the adsorbent, is found to be expressed by $\log c = a\sqrt{\lambda} - b$, where c is the quantity of gas adsorbed per unit weight of adsorbent, λ the latent heat of evapn., and a and b are consts. which are for a given adsorbent independent of the nature of the gas, but vary with temp. and pressure. The equation, which has also been derived theoretically, is applicable to the adsorption of gases by colloids and by liquids. Deviations are found when chem. reaction takes place readily. If ionization of the adsorbed gas occurs, forces of attraction, addnl. to those of van der Waals, are called into play, and the force needed for sepn. of the mols. of the gas is greater than the calcd. values. B. C. A.

Our knowledge of catalysis. RICHARD WILLSTÄTTER. *Z. Ver. deut. Ing.* **72,** 901–5(1928).—The history of catalysis is briefly discussed with the earlier ideas concerning catalysis and the intermediate compds. theories. Examples of catalytic processes are given among which are the NH_3 synthesis, acid and basic catalysis in org. reactions, the use of mixed catalysts in the methanol and hydrocarbon synthesis, and enzymes in biological processes and enzymes. M. R. FENSKE

Influence of arsenic on the catalytic activity of platinum for the oxidation of sulfur dioxide. EDWARD B. MAXTED AND ARTHUR N. DUNSBY. *J. Chem. Soc.* **1928,** 1600–3.—In accordance with other known data on catalytic poisoning the first amts. of poison produce the greatest effects. The first part of the curve for catalytic activity *vs.* mg As per 0.35 g. of Pt is approx. a straight line up to about 0.7 mg. As. The first 0.7 mg. As per 0.35 g. Pt. reduces the activity to 45% of its original value, and a further 9.3 mg., *i. e.*, 13 times the first wt. of poison only depresses the activity from 45 to 26% of its original activity. M. R. FENSKE

Interpretation of the sugar inversion by the dualist catalysis theory and by the activity of hydrogen ions. M. Duboux and R. Mermoud. *Helv. Chim. Acta* **11,** 583–97(1928).—The inversion of sugar has been carried out in the presence of HCl (0.091–3.6N) and HNO_3 (0.74–3.69 N). No proportionality exists between the velocity const. and the H-ion concn. as detd. by cond. The dualist catalysis theory gives an erroneous explanation of the observed facts. In the first approximation, the velocity const. is proportional to the H-ion activity, when the catalyst is HCl. A. L. H.

Active surface of catalysts. Bennosuke Kubota. *J. Fuel Soc. Japan* **6,** 149–55; *Chem. Zentr.* **1927,** II, 1536; cf. *C. A.* **22,** 1520.—Explanations which have been suggested by various investigators dealing with the active surface of catalysts are reviewed, and expts. are described in which Ni catalysts prepd. at various temps. were used with 3 types of compds., *viz.*, aromatic hydrocarbons, aliphatic hydrocarbons and C-free compds., using also a catalytic poison. It is concluded that Ni "consists of various inorg. ferments," that there is a constitutional relationship between these "ferments" and hydrogenating substances and that the Ni surface has a sp. action. C. C. D.

Catalytic action of mineral waters. F. C. Gaisser. *Z. angew. Chem.* **41,** 401–7 (1928).—The benzidine reaction has been investigated for a no. of naturally occurring waters. Those showing a pos. reaction invariably contain ferrous or manganous ions, or both but the converse does not hold. Further, waters contg. Fe and Mn are the most active catalysts of the decompn. of H_2O_2. The explanation of these relationships, however, remains obscure. Expts. have also been made on the catalytic activity of the waters during the hydrolysis of starch. B. C. A.

Partial oxidation of methane and ethane in the presence of catalysts. T. E. Layng and R. Soukup. *Ind. Eng. Chem.* **20,** 1052–5(1928).—The catalytic partial oxidation of various mixts. of CH_4 and C_2H_6 and also of natural gas with O was studied by the dynamic method within the temp. range of 100–700°. For the production of alcoholic or aldehydic intermediates, catalysts of Cu and Ag and oxides of these metals, activated charcoal, Pt oxide and BaO_2 proved unsatisfactory on the basis of hydrocarbon consumed and products obtained. On using small amts. of NO_2 and passing the mixt. through capillary tubes yields of 15–30% of oxygenated derivs. were obtained. Auxiliary catalysts proved ineffective. $MeNO_2$ promotes the partial oxidation. D. F. Brown

Studies on catalytic action. XXII. Catalytic action of reduced copper on unsaturated hydrocarbons. Shigeru Komatsu and Masao Kurata. *Mem. Coll. Sci. Kyoto Imp. Univ. Series A* **11,** No. 3, 163–9(1928); cf. *C. A.* **22,** 1265.—The monocyclic terpenes, menthene, *d*-limonene and β-phellandrene were converted by non-reversible catalysis of reduced Cu into cymene and menthene. 54 g. of menthene was passed over Cu catalyst prepd. from 10 g. of CuO, at the rate of 4.5 g./hr. at 290–300°. The product consisted of menthane, cymene and unchanged menthene. Passing *d*-limonene at 280–300° over Cu catalyst yielded completely cymene. At 200° and a rate of 4 5 g. per hour cymene and menthane were found in the product. When 5.3 g. of phellandrene was passed in 2 hours over a Cu catalyst at 300°, the product contained cymene and menthane. M. R. Fenske

The catalysis of oxidation by iron according to Handovsky. Otto Warburg. *Biochem. Z* **198,** 241–2(1928).—Handovsky's theory that catalysis of oxidation by iron in charcoal is due to the H_2 gas which the Fe contains is questioned. S. M.

Acid and salt effects in catalyzed reactions. XV. Catalytic activity of hydrochloric acid in the hydrolysis of ethyl acetate. Harry M. Dawson and Wm. Lowson. Univ. Leeds. *J. Chem. Soc.* **1928,** 2146–54; cf. *C. A.* **22,** 3338.—The concn. range of HCl as catalyst for the hydrolysis of EtOAc is carried much lower than in previous work (0.01N). At a concn. of 0.01N HCl, the hydrolysis is markedly affected by the AcOH. This factor must be taken into account in any consideration of thermodynamic activity of H ion. The sep. influence of AcOH was carefully studied. For the range of concn. 0.0002–0.2N HCl, the constancy of k within the limits of exptl. error shows that the initial velocity of hydrolysis is proportional to the concn. of HCl. Over this range the mean activity coeff. falls from 0.997 to 0.884. There is no apparent connection between the catalytic activity and the thermodynamic activity. **XVI. Catalytic effects in the iodination of mesityl oxide.** Harry M. Dawson and Arthur Key. *Ibid* 2154–65.—The reaction between mesityl oxide and I in dil. aq. soln. is similar to but 200 times more rapid than the reaction between acetone and I. Varying results from samples of the same sp. gr. and n (cf. Harries, *Ber.* **32,** 1329(1899); *Ann.* **330,** 189(1904)) were due to impurities. The reaction is probably of the keto-enol type. The curve for log x *vs.* time is approx. a straight line, for the later stages of the reaction. (x = concn. of the catalytically active H ion.) Considerable deviation was found,

however, in the early stages, showing autocatalytic effects which are accounted for by the joint catalytic effect of the H ion and the undissocd. water mol. The relative values for the catalytic coeffs. for H^+, OH^-, H_2O, CH_3COOH, $CH_3CO_2^-$, $H_2PO_4^-$, and HPO_4^{--} vary considerably from their relative values for the acetone reaction.
A. J. Currier

Synthesis of organic substances and of ammonia starting with water gas without employing catalyzers. Brutzkus. *Compt. rend.* **187,** 124–5(1928).—Control of temp., pressure, and concn. has demonstrated the truth of the deduction "All chem. reaction can be directed and accelerated in a given direction by exterior variations, continuous and simultaneous, of pressure, temp., and concn. of different substances acting in opposed direction to those of variations provoked by the desired reaction." The greatest pressure employed was 50 atm.
L. D. R.

Autoxidation and antioxygen action. Catalytic properties of phosphorus compounds. Charles Moureu, Charles Dufraisse and Marius Badoche. *Compt. rend.* **187,** 157–61(1928).—PBr_3 is a good antioxygen for BzH in 1 part per 1000. H_3PO_2 is a less active antioxygen for furfurole and BzH. H_3PO_3 is very good for furfurole while Na_2HPO_3 suppresses the oxidation of BzH. H_3PO_4 is also a good antioxygen The tertiary phosphines, in general, are good antioxygens. Dimethylphenylphosphine, diethylphenylphosphine, methyldiphenylphosphine, ethyldiphenylphosphine protect well BzH, furfurole and styrolene. The primary and secondary phosphines are less active.
M. R. Fenske

Autoxidation and antioxygen action—catalytic properties of phosphorus. Charles Moureu, Charles Dufraisse and Marius Badoche. *Compt. rend.* **186,** 1673–7 (1928).—The action of white P on the antioxidation of BzH, oil of turpentine and furfurole was studied. It is possible that the active catalyst with white P is due to some product of oxidation. The effect of red P is similar to that of white P but less intense.
M. Fenske

Catalysts for the reaction $CO + H_2O \rightleftharpoons CO_2 + H_2$. W. Dominik. Main School of Agr., Warsaw. *Przemysl Chem.* **12,** 229–35(1928).—From theoretical considerations the following equation for $CO + H_2O \rightleftharpoons CO_2 + H_2$ is derived $\frac{x - x_2}{x - x_1} = \frac{x_0 - x_2}{x_0 - x_1} \cdot e^{-b(K-1)(x_1 - x_2)1/V}$. This is like that for bimolecular reactions in homogeneous systems. b is a const. which characterizes the useful surface of the catalyst at a given temp., $K = [CO_2][H_2]/[CO][H_2O]$ = equil. const at a given temp., V = space velocity of the gas vapor mixt. in cm.³/hr./g. of catalyst, x = partial pressure of CO_2 in the reaction mixt., x_0 = partial pressure of CO_2 before the reaction, x_1 and x_2 the 2 roots of the equation

$$\frac{x(p_0H_2 + x - x_0)}{\{p_0CO - (x - x_0)\}\{p_0H_2O - (x - x_0)\}} - K = 0,$$

in which p_0H_2, p_0CO and p_0H_2O represent the partial pressures of the respective components before the reaction and only x_2, the root with the negative radical, represents the pressure of CO_2 at equil To test this exptly. the extent of the reaction was measured after the gaseous mixt had passed over one and over two exactly equal portions of the catalyst under the same conditions. A whole series of detns. shows that the catalysis of water gas does proceed according to the derived equation, but that possibility of small difference of temp. lowers the accuracy of the detns.
A. C. Zachlin

Acid and basic catalysis. J. N. Brønsted. Univ. of Copenhagen. *Chem. Reviews* **5,** 231–338(1928).—In the text the field of acid and basic catalysis is covered up to March 1926. In an appendix the progress in 1926–1927 is included. In the review a crit. exposition of the theories of acid and basic catalysis is given and also an outline of the modern views on catalytic salt effect. The phenomena of acid and basic catalysis are discussed on the basis of views of the acid-basic function which have their foundation in the work on the catalytic decompn. of nitramide and reactions like the mutarotation of glucose.
M. R. Fenske

Researches on catalysis at reduced pressure. V. Grignard. *Bull. soc. chim.* **43,** 473–91(1928); cf. *C. A.* **22,** 1890.—The app. used in the low-pressure expts. is described. The catalysts used were Ni, Cu, Pt black and Pt oxide of Vorhees and Adams They were supported on fine pumice. Revivification of the catalyst by means of O_2 was also used. The hydrogenation of tertiary methylheptenols $Me_2C{:}CHCH_2CH_2CMeROH$, was studied since they do not hydrogenate normally by the usual catalytic methods. With Ni at ordinary pressure at 180–200°, hydrogenation yields the satd. hydrocarbon With Pt methylheptenone and the hydrocarbon are formed. But with Ni at about 15 mm pressure, hydrogenation of the alc. begins at 90°; it is about ³/₄ complete at 90–100° and

essentially quant. at 160–170°. The velocity of hydrogenation at 15 mm. is not much different from that at ordinary pressure. At low pressure desorption is more rapid and so the life of the mol. on the catalytic surface is appreciably reduced. Hydrogenation of benzonitrile with Ni at 175° and 10–13 mm. yields the imine, $C_6H_5CH = NH$ The mechanism of the hydrogenation of phenol was studied. Cyclohexanol begins to yield cyclohexanone at 155° at 18-22 mm.; at 50 mm. the temp. is 160°, while at 760 mm. the temp. is 180°. With benzoyl chloride at 300° and ordinary pressure with Ni benzaldehyde, benzene, toluene and benzoic acid were formed. But by hydrogenating at the same temp. but at 300 mm. a yield of 60% benzaldehyde was obtained. The nickel catalyst rapidly loses its activity as a result of the formation of $NiCl_2$, but with Pt or Pt oxide excellent results were obtained. At 225° and 140 mm., 60% of the benzoyl chloride is converted into benzaldehyde principally. Phenylpropionyl chloride at 200° and 400 mm. yields 20% aldehyde, with the remaining 80% unchanged. The reduction of aromatic aldehydes and ketones was also investigated. With benzaldehyde and Ni at 200° and ordinary pressure, about 58% was reduced to toluene, while the rest was decomposed into CO and C_6H_6. At 150° and 25 mm., 40% of the aldehyde is reduced to benzyl alcohol; at 100 mm and 150°, 67% reduction to alcohol is attained. Increasing the temp. to 180–200° forms besides the alcohol, a viscous condensation product distg. at 200° under 6 mm. In addn. the mechanism of the hydrogenation, of α-ethylenic ketones, and the dehydrogenation of alcohols was studied.

M. R. Fenske

The Landolt-reaction. V. The catalytic action of sodium thiosulfate on the Dushman-reaction. Wadim Roman-Levinson. *Z. Elektrochem.* **34,** 333–50(1928).—The Dushman-reaction is: $IO_3^- + 5I^- + 6H^+ = 3I_2 + 3H_2O$ Three related reactions are (1) the Dushman-S-reaction, *i. e.*, the above reaction in the presence of sulfite as reducing agent, (2) the Dushman-T-reaction, *i. e.*, the reaction occurring in the presence of thiosulfate as reducing agent; and (3) the Dushman-S-T-reaction, *i. e.*, thiosulfate catalyzing the reaction used with sulfite. As long as the thiosulfate concn is small compared to the sulfite concn., the S-T reaction is the principal time-detg reaction. The reaction time decreases with increase in thiosulfate concn. and reaches a min when the thiosulfate concn is commensurate with the sulfite concn. From here on the T-reaction dets the time, the reaction time increasing with increasing thiosulfate concn. The formation of various complex compds of the iodate, iodide, sulfite and thiosulfate ions are discussed.

M. R. Fenske

Equilibrium between hydrogen-carbon monoxide and methane-carbon dioxide in the corona discharge. Gerald L. Wendt and Gregg M. Evans. *J. Am. Chem. Soc.* **50,** 2610-21(1928). The gaseous phase in the reaction, $2 CO + 2 H_2 = CO_2 + CH_4$ reaches an equil at a compn of 37.1% CO, 37.6% H_2, 13.3% CO_2 and 8.7% CH_4, corresponding thermodynamically to 900-950° K. Contraction continues, however, and the end products are C and H_2O.

G. M. Evans

The system sodium carbonate sodium bicarbonate-water and the region of existence of trona, $Na_2CO_3.NaHCO_3.2H_2O$. Rudolf Wegscheider and Josef Mehl. Univ. Wien *Monatsh.* **49,** 283-315(1928).—The equil. between aq solns. of Na_2CO_3 and $NaHCO_3$ and the pptg solid phases, in the absence of NaCl, was measured at 11 different temps between 20° and 94.5°. In the presence of NaCl it was studied at 3 temps At 90°, 1 or 2 double salts sep. which are richer in CO_2 than trona, $Na_2CO_3.NaHCO_3.2H_2O$ This on decompn. by water gives labile Na_2CO_3.

M. R. F.

Chemical equilibrium in the vapor of a mixture of paraffins and unsaturated hydrocarbons. H. A. Wilson Rice Institute, Houston, Texas. *Proc. Roy. Soc.* (London) A120, 247-51(1928); cf. *C. A.* **22,** 902.—Using the same method of attack as in previous paper, W derives the equation $y = {}^1/_2 - \sqrt{{}^1/_4 - K'f/p(1-f)}$, where y is the fraction of the total pressure p due to unsatd. hydrocarbons in equil. with liquid and vapor The calcd. results show that doubling the pressure diminishes the unsatd. compds in vapor to ${}^1/_3$, while raising the temp. 50° F. should double them. The max. mol percentage of unsatd compds. in vapor is 50% for equil. conditions. If values of $K'f/p(1-f)$ greater than ${}^1/_4$ are chosen equil. cannot be established and decompn. will go on till only vapor remains. This is the case at 15 atms. and at temps. 825, 850, 875° F It is well known that the amt. of unsatd. compds. is diminished by increasing the pressure. Coke may be considered as a highly unsatd. hydrocarbon; the rate of coking increases with temp. rise, and is lowered by increasing pressure since it is an unsatd compd.

Arthur Fleischer

The definition of "area" in the case of contact catalysts. F. Hurn Constable. St. John's College, Cambridge, England. *Nature* **122,** 399–400; cf. *Proc. Roy. Soc.* (London) A119, 196(1928); cf. *C. A.* **22,** 3818.—The area of an activated contact catalyst will

vary with the method of measurement adopted. It is thus essential that the max. area of a surface should be defined carefully, so that the results of all measurements can ultimately be compared with this standard. At the present time it seems best to define the "max." area of a surface as the area of the envelope of H atoms covering it completely with a unimol. film, because this gives as nearly as possible an abs. definition. The measurement of this max. area is a matter of great difficulty. The interface method, the H adsorption method, and the electrolytic H deposition method all give results less than the max. area. R. L. DODGE

Equilibrium in binary systems containing urea as one component. NIKOLA A. PUSCHIN AND DESIDER KÖNIG. Univ. Zagreb. *Monatsh.* **49,** 75–82(1928).—The phase diagrams of 8 binary systems contg. urea plus one of the following were constructed, the method of thermal analysis being used: trichloroacetic acid, phenol, resorcinol, hydroquinone, guaiacol, α-naphthol, naphthalene and diphenyl. The data show that urea with trichloroacetic acid, resorcinol, hydroquinone and phenol forms definite compds., the first 3 forming substances of equal molal compn., while those with phenol consist of 1 mol. of urea with 2 mols. of phenol. In the cryst. state urea with guaiacol and α-naphthol form only mech. mixts.; with naphthalene and diphenyl, urea is not miscible in the liquid condition but seps. into 2 layers. M. R. FENSKE

Ternary systems. VII. The periodates of the alkali metals. ARTHUR E. HILL. N. Y. Univ. *J. Am. Chem. Soc.* **50,** 2678–92(1928).—Study of the 25° isotherm for the system KIO_4-KOH-H_2O showed that only 2 stable salts form from aq. soln., namely, KIO_4 and $K_4I_2O_9.9H_2O$. The soly. of these salts in H_2O was detd. between 0° and 100°. $K_4I_2O_9.9H_2O$ undergoes a transition to the anhyd. form at about 78°. Three stable Na salts form from aq. soln in the system $NaIO_4$-$NaOH$-H_2O, namely, $NaIO_4.3H_2O$, $Na_2H_3IO_6$, and $Na_3H_2IO_6$. The soly. of Na metaperiodate, $NaIO_4$, was detd. between 5° and 50°. A transition point between the hydrate and the anhyd. form occurs at 34.5°. The wide difference in the soly. of KIO_4 and $NaIO_4$ may be used as a means for the analytical sepn. of K and Na. The secondary Na periodate, $Na_2H_3IO_6$ is found, when in an amorphous condition, to hold a small quantity of H_2O with a vapor tension apparently as low as that of the compd.; at 100° the rate of loss of H_2O, adsorbed or of compn., averages about 0.01% per day under atm. aq. pressures. The tertiary salt also adsorbs H_2O, and the rate of loss of H_2O adsorbed or of compn. is about $^1/_6$ as great. Action of HIO_4 on metalperiodates did not produce acid salts. $LiIO_4$ could not be formed in a pure state. NH_4IO_4 could not be formed at all by the oxidation of the iodates by Cl_2 in the presence of the appropriate bases. R. H. LOMBARD

Generalization of the methods of residues; determination of the degree of hydration of solid phases in systems in equilibrium. V. P. SHISHOKIN. *Ann. inst. anal. phys.-chim.* (Leningrad) **3,** 746–9; *Chem. Zentr.* **1927,** II, 2702; cf. *C. A* **22,** 3802.—The method of Schreinemaker (*Z. physik. Chem.* **11,** 81(1893)) which allows the detn. of the constitution of the ppt. present as the solid phase if the compn. of the soln. and the compn. of the soln. plus the solid phase are known, is applied to the detn. of the sepd. salt. *E. g.*, with a NaCl-$MgSO_4$ soln. with NaCl and a $MgSO_4$ hydrate as solid phases it is sufficient to analyze a sample of the soln. and of the total residual system to ascertain the compn. of the hydrate (*C. A.* **21,** 3802). C. C. DAVIS

Freezing point-solubility relations of geometrical isomers. I. The β-chlorocrotonic acids. EVALD L. SKAU AND BLAIR SAXTON. Yale Univ. *J. Am. Chem. Soc.* **50,** 2693–2701(1928).—Measurements of f. p. for the system β-chlorocrotonic acid-β-chloroisocrotonic acid with an *improved f. p. app.* (cf. *C. A.* **20,** 136) show straight lines for $1 + \log N$ *vs.* $1000/T$ and heats of soln. of 5220 and 4120 cal. per mole for the normal and iso acids, resp. Calorimetric data for heats of fusion differ by 270 and 820 cal. per mole, resp., in the same direction corresponding to values 3° and 5° below those observed near the eutectic compn. Heat contents, sp. heats and heats of fusion are reported. Comparison of these data and those for the crotonic acid-isocrotonic acid system indicate that geometrical isomers show small deviations from mutual ideality but not such as would indicate complex or mixed-crystal formation. Possible explanations are a slight difference in the internal pressures or polarity of the 2 substances or a slight heat of mixing. Less polar isomers may be more nearly ideal. FOSTER DEE SNELL

Deviations from the regular temperature scale. F. HENNING AND J. OTTO. Berlin-Charlottenburg. *Z. Physik* **49,** 742–8(1928).—A crit. review is given of the phys. basis for the 6 values adopted for the international temp. scale by the Oct. 4, 1927 Conference of Weights and Measures in Paris. It is concluded that these values do not differ from earlier temp. scales by more than the exptl. errors involved in the detns. H. R. MOORE

The temperature of the vapor from a solution. K. Schreber. *Z. tech. Physik* **9,** 277–85(1928); cf. *C. A.* **21,** 1368.—For accurate measurement of the temp. of water vapor evolved by a boiling salt soln. the Ruoberg arrangement (up and down circulation of vapor through concentric jackets surrounding the distn. column) was improved on by heat insulation. The total height of the column was 500 mm., the diam. of column proper and jackets 40, 80 and 140 mm.; five thermoelements were used for the measurements, 7 Hg thermometers for control. The accuracy was 0.2°. The boiling vessel was 100 × 95 mm. heated by electricity. After proper equil. had been established the temps. were read every 10 min., superheating of the thermometers was eliminated as shown by boiling pure water. The result found was (in agreement with Faraday's contention, contrary to Gay Lussac) that the vapor entering the column is cooler than the boiling liquid; the vapor leaves the soln. probably at the temp. of boiling pure solvent. B. J. C. van der Hoeven

The limiting value of the latent heat of vaporization and of the specific heat of saturated vapor at zero absolute. Nikolaus v. Kolosovskii. *Z. physik. Chem.* **136,** 314–6(1928).—Proofs by Van Laar and others based on assumption that latent heat is finite and therefore that the sp. heat of satd. vapor is $-\infty$ at $T = 0$ are pure tautologies. F. R. B.

Thermal dissociation of cadmium nitrate. G. Malquori. Univ. of Rome. *Gazz. chim. ital.* **58,** 217–22(1928).—See *C. A.* **22,** 2333. C. C. Davis

Physicochemical studies on higher fatty acids. I. The thermal analysis of the binary mixtures of the stearic and palmitic acids and of the stearic and of the palmitic triglycerides. N. N. Efremov. *Ann. inst. polytech. Oural* **6,** 155–204(1927).—E. shows by means of f. p.-concn. diagrams that the system of the 2 acids has the behavior typical of a mixt. of 2 isomorphous compds., the diagram having only one min. at 52.5° and 68% by wt. of palmitic acid The solid solns. of the acids are not quite stable. They decompose very slowly, yielding probably either a mech. mixt. of the components of eutectic compn., or a chem. compd. of varying compn. of the so-called Bertollid type. By his measurements of the viscosity and by the study of the microstructure of the binary system, E. is able to confirm entirely his results of thermic analysis. The stearic and palmitic triglycerides do not have double m. ps., as has been stated sometimes. E. finds instead that both esters exist in at least 3 polymorphous modifications each. The stable α-modifications are formed on rapid cooling of the molten stearic and palmitic glycerides. Their m. ps. are 53.2° and 48.4°, resp. The β-modifications can be obtained by a very slow cooling of the glycerides. They are of a soft texture and transparent and are stable in the temp. range 55.2–64.9° and 53.8–60.0° correspondingly. Crystn takes place, however, usually only below 55.2° and 53.8°, because of strong and unavoidable undercooling of the liquids. The α-modifications can be easily superheated and transformed into β modifications without melting at 53.2° and 55.2° correspondingly. By careful heating of the latter modifications above 64.9° and 60.0°, γ-modifications can be obtained. These are non-transparent, have m. p. at 69.3° and 67.5° and cannot be obtained by crystn. from the molten compds. directly, as either α- or β-modifications are then formed. The f. p.-concn. diagrams of the binary mixts. of the 2 esters show that all 3 modifications form solid solns. of the 3rd type according to classification of Roozeboom. The α-modifications have the eutectic at 44.9° and 79.5% by wt. of palmitic glyceride. Similar and symmetrical results are obtained with β- and γ-modifications. The first have eutectic at 47.8° and 75% of 3-palmitic ester, the second at 52.3° and 72.4%. G. B. Kistiakowsky

Heats of solution and dilution of some strong electrolytes. Erich Lange. *Fortschritte Chem. Physik physik. Chem.* **19,** No. 6, 1–83(1928).—The first half of the paper is a theoretical treatment of the various heats of soln. and diln., including factors affecting their values, relationships among them, and theories of the heat of soln., especially in the limiting case of infinite diln. After a survey of methods for detg. these heats, full descriptions are given of an adiabatic calorimeter for detg. large heats and a differential adiabatic calorimeter with a sensitivity of $5 \times 10^{-6°}$. With this, heats of diln. for chlorides, sulfates and nitrates of different valence types were detd. All salts showed positive heats of diln. at very great diln. in accordance with the Debye-Huckel theory. The heats of diln. of 5 alkali halides at concns. below 0.01 *M* agree as the theory of equal types demands, but all salts examd. are not consistent in this respect. The temp. coeff. of the heat of diln. as detd. for two salts is below the theoretical value. Lucy K Pickett

The specific heats of gases and their importance in the calculation of "chemical constants." Schmolke. *Wärme* **50,** 395–400; *Chem. Zentr.* **1927,** II, 1497.—A

study of the application of the kinetic theory of gases and the quantum theory to sp. heats shows that the theories could not hold a step further in the realms of high-pressure steam and heat transfer. New theoretical investigations are therefore necessary.
J. S. REICHERT

The state and specific heat of gases at infinite volume. R. D. KLEEMAN. *J. Franklin Inst.* **205,** 691–8(1928).—A theoretical paper. W. T. RICHARDS

Specific heats of superheated steam and gases at high temperatures and pressures. VITTALE GALLINA. *Ann. scuola ing. Padova* **4,** 77–87(1928).—A review of various equations of state including those of van der Waals, Clausius, Sarrau, Amagat, Kamerlingh Onnes, Planck and Callendar. A. W. CONTIERI

The heat of combustion of benzoic acid. W. A. ROTH. *Z. physik. Chem.* **136,** 317–20(1928).—The value of Roth, Doepke and Banse (following abstract) for the heat of combustion of fused BzOH (26.433 kilojoules at constant volume per g. in vacuum) agrees with best old values. The heat of combustion of iron wire to Fe_3O_4 is 1.58 cal per mg. F. R. B.

Absolute determination of the heat of combustion of benzoic acid. W. A. ROTH, O. DOEPKE AND HILDEG. BANSE. Tech. Hochschule, Braunschweig. *Z. physik. Chem.* **133,** 431–42(1928).—Because of contradictions in the literature, the heat of combustion of BzOH has been redetd. Two independent investigations were carried out with different heat resistances, different methods of measurements and different samples of BzOH. Since cryst. BzOH is hygroscopic, in one detn. the fused salt was used, care being taken to seed the melt with an original crystal so as to avoid the formation of another form of the acid. The thermometer could be reliably estd. to 0.0005°. The bomb was a Langbein-Hugerstoff model, lined with Pt and completely immersed. The pressure of the O used was 35 atms. The calorimeter was not worked adiabatically. The av. value is 6323 cal$_{15}$. S. L. B. ETHERTON

Heat of combustion of benzoic acid in the international joule. W. JAEGER AND H. V. STEINWEHR. Physikalisch-Technischen Reichsanstalt. *Z. physik. Chem.* **135,** 305–46(1928).—The exptl. method is given in complete detail. The measurements of temp. and the complete technic are fully described. The av. value of a no. of combustions on BzOH from different sources is 26.437 kilojoules per g. at 19.3°. Comparison is made with the value of Fischer and Wrede, 26.449 kj. and of Dickinson, 26.436 kj. The mean of these values is 26.441 kj. per g., or at 15°, the heat of combustion is given as 6319.3 cals. per g. M. R. FENSKE

Heat capacities of organic compounds at low temperatures. I. Precision calorimeter and thermostat for low temperatures. DONALD H. ANDREWS. *J. Franklin Inst.* **206,** 285–99(1928).—In designing this calorimeter to measure accurately the sp. heats of org. compds. between —200° and room temp., certain exptl. difficulties were faced, *viz.:* these compds. have low heat cond.; many are corrosive; many can be obtained only in very small quantities. The calorimeter proper consists of an 18-karat-gold vessel of about 100-cc. capacity. A reentrant tube from the bottom supports through the center a no. of gold disks which serve to distribute the heat from the heating coil in the tube to the contents of the calorimeter. A carefully designed thermostat with automatic photoelec. temp. control makes it possible to maintain the calorimeter in a vacuum-jacketed chamber at any desired temp. between —180° and 50° to within 0.01. An automatic device keeps the heating coil in circuit for exactly 3 min., accurate to $^1/_{60}$ sec. The rise in temp. of about 2° produced in the calorimeter and its contents is measured by carefully calibrated thermocouples with an accuracy of about 0.005 at —180° and 0.001° at room temp. Results are given for heptaldehyde, ranging from 0.258 cal. per g. at —167.57° to 0.431 cal. per g. at —80.32°. Full details of the various pieces of app. are given. W. W. STIFLER

The electron thermochemistry of inorganic substances. A. BERKENHEIM. Second State Univ. of Moscow. *Z. physik. Chem.* **136,** 231–58(1928).—Many inorg. substances, such as the halides and oxides, show regularity in their *heats of formation* both in vertical and horizontal rows of the periodic table. Since, according to Born, the heats of formation may be resolved into the sum of the heats of sublimation, of ionization, of dissocn. and the energy of electrostatic attraction, these last should also show periodic regularity. B. finds that they do, and he also finds that there is similar regularity among ionic radii. By means of these relationships, he is able to calc. the lattice energy of the alkali halides and the alk. earth oxides and obtains results which agree well with those of Born. MALCOLM DOLE

Thermodynamic deduction of Maxwell's distribution law. A. N. SHCHUKAREV. *Physik. Z.* **29,** 181–2(1928).—Maxwell's deduction is open to criticism, although the

law is in accord with experience. An attempt has therefore been made to deduce the law from thermodynamic principles. B. C. A.

The second law of thermodynamics in general relativity. RICHARD C. TOLMAN. Cal. Inst. of Technology. *Proc. Nat. Acad. Sci.* **14,** 701–6(1928); cf. *Proc. Nat. Acad. Sci* **14,** 268, 348, 355(1928).—In an extension of thermodynamics to general relativity a postulate analogous to the second law has previously been presented. Originally this had the form which it took when applied to an isolated finite system and was justified by showing that it reduced to the second law in the limiting case. In the present work the new postulate is regarded in the form it takes when applied to a non-isolated infinitesimal system. The new form also leads to an expression for the entropy of a system in a stationary state, which agrees with the usual relation between entropy and probability. H. F. JOHNSTONE

Note concerning thermodynamic calculations. DAVID F. SMITH. U. S. Bureau of Mines. *Ind. Eng. Chem.* **20,** 859–60(1928); cf. *C. A.* **21,** 2783.—The synthesis of hydrocarbons especially C_6H_6, from water gas is considered. The rate of reaction is stressed as an important factor, for free-energy values alone will not tell what species predominates. Comments are made on Francis' calcns. of the free energies of various hydrocarbons and alcs. (*C. A.* **22,** 1131), and it is pointed out that the use of thermal data often leads to erroneous results. Values obtained from equil. consts., where all substances involved are at the standard fugacity of 1 atm., are more reliable H. R. MOORE

Thermodynamics based on statistics. I. GILBERT N. LEWIS AND JOSEPH E. MAYER. Univ. of Calif. *Proc. Nat. Acad. Sci.* **14,** 569–75(1928) —The basis of statistical treatment has been Planck's view that the abs. entropy is the total no. of possibilities of a system. Systems may be treated by considering every change in the system or by limiting the variables, *i. e.*, inhibited systems. A system is completely defined by (1) energy, (2) vol and (3) amt of each species of independent constituent. The basis of the present treatment is the partition of mols. into regions. The *detailed regions* are described by specifying the no. of mols of each independent constituent in the region. If a system is divided into J and K (spacial, energy, or mol. species distribution) there is a finite no. of detailed states that the system as a whole can assume. Ω represents the possible no of detailed states, d a given distribution. The following equation is deduced: $(\log \Omega^d_J) + (\log \Omega^d_K) = 0$. Ω^d, the no. of states at equal distribution, always smaller than Ω but Ω^d always greater than average no. of states of distribution. For the equil. distribution, except for small nos. and regions $\log \Omega^d = \log \Omega$. For every system there is a natural mode of partitions into regions which dets. the $\log \Omega$. If certain inhibitions are accepted they must be abided by in detg the $\log \Omega$. This comprises the 2nd and 3rd laws of thermodynamics. The essential idea involved is that thermodynamic properties are detd. with all possible exactness when detailed states are specified to a finite degree. Conversely, thermodynamic properties det. mech. states only within finite limits. **II.** *Ibid* 575–80.—From the equations derived for Ω, the total no. of regions, the equations $(dS/dE)_V = 1/T$, $(dS/dV)_E = P/T$, and $(dE/dV) = -P$ are derived. The identity of S, T and P are then proved to be the thermodynamic quantities entropy, temp. and pressure. From the above fundamental equations, the remaining equations of thermodynamics can be derived. ARTHUR FLEISCHER

Formulas for the internal energy and entropy of a substance or mixture. R. D. KLEEMAN. *J. Phys. Chem.* **32,** 1396–1410(1928).—A theoretical paper. W. T. R.

Measurements of the thermal conductivity of crystals and crystalline material. A. EUCKEN. *Fortschritte Mineral. Kryst. Petrog.* **12,** 31–2(1927).—Mixed crystals of alkali halides showed poorer thermal cond. than the pure halides. There was found to be no relation between thermal cond. and hardness. J. F. SCHAIRER

Thermal conductivity of metals and nonmetals. A. EUCKEN. *Physik. Z.* **29,** 563–6(1928).—E reviews the Debye theory of thermal cond. and its exptl. verification, for non metallic crystals and crystal masses. The roles of the electron and the lattice in the thermal cond. of metals are also discussed (cf. *C. A* **22,** 3090). R. L. H.

Hall effect in single metal crystals. P. I. WOLD. *Science* **68,** 183–4(1928).—The Hall effect in single crystals of Si steel (3.8% Si) was approx. 15 times as great as that for pure Fe. It is independent of the direction of orientation of the crystal, and this is true also for single crystals of Cu. Taken in connection with recent work of Van Everdingen this suggests that further investigations on the possible effects of crystal orientation on the Hall effect should be made on metals which do not have a cubic lattice structure. W. W. STIFLER

Practical pyrometry. G. B. Brook and H. J. Simcox. *J. Inst. Metals* No. **470,** 10 pp.(1928).—Temp. indicators can be satisfactorily protected against magnetic effects by shielding with soft-iron plates, thereby increasing the accuracy of readings taken. A double shielding with air-gap showed an even greater advantage. An instrument embodying these and other special features is exhibited. Where several couples are connected to the same recorder, trouble is often experienced by the interference of one couple with another, because of contact of the couple with the sheath tip. This can be overcome by using a thimble of insulating material on the end of the thermocouple to protect it from the sheath. The use of lead-covered paper-insulated cable is recommended as connecting cable between the couple and the recording instrument. Cast Fe, coated regularly with a wash of equal parts of French chalk and graphite mixed to the consistency of a thick cream with 10% Na silicate soln., has been found by expt. to be the best material for a thermocouple-protecting sheath for resisting the attack of molten Al. Since couples, particularly those contg. Ni, are very susceptible to the attack of S in the furnace gases, it was found possible, by using lime between the inner and outer sheaths, not only satisfactorily to protect the Ni, but also to enable the couples to be used at a temp. at least 100° above the max. recommended by the makers of the wire. A quick-reading couple suitable for use in many non-ferrous metals can be made by leaving about $^1/_2$ in. of wire bare at the end of the couple, the rest being insulated with silica tubing of small bore, protected by asbestos cord. The contact between the wires is not made by twisting, as is usually the case, but by the molten metal itself. Such a couple enables the operator to read the temp. in about 15 sec. M. R. Fenske

Measurement of the temperatures of stationary flames. A. G. Loomis and G. St. J. Perrott. *Ind. Eng. Chem.* **20,** 1004-8(1928).—The method of Kurlbaum Fery (described in detail) was used to measure the flame temps of CH_4, C_2H_6, natural gas and CO mixts The method consists in comparing the brightness temp. of a continuous radiator, *viz.*, a W band lamp, with the brightness of the radiation from the flame colored with NaCl vapor at $\lambda = 0.589\mu$. It is shown that the true flame temp is equal to the brightness temp of the W radiator, as read with an optical pyrometer when the spectral line is just reversed as seen in a spectrometer. Comparison of these values with those obtained by means of the Natl. Phys. Lab.'s method giving temp. as a function of the current heating a Pt strip gave agreement within 20°. Calcd. temps. based on thermodynamic principles employing values of ΔH and sp. heats from the work of Lewis and Randall (*C. A.* **20,** 1941) differed from 25° to 70°. H. L. O.

Measurement of flame temperatures. Ezer Griffiths and J. H. Awbery Brit. Nat. Phys Lab. *Gas. J.* **183,** 596(1928); *Gas World* **89,** 261(1928).—Two methods are discussed In one, a refractory metal in the form of wire is heated electrically *in vacuo*, and the relation between temp. and heating current is detd. by an optical pyrometer. The same wire is then inserted into the flame, and the relation between temp. and heating current is again detd. When the results are plotted graphically, the point of intersection of the two lines will give the temp. of the flame, for at the temp represented by this point the electrical supply is sufficient to balance the radiation loss, whether the wire is in vacuum or in the flame, so that the surrounding gas in the flame neither imparts nor abstracts heat from the wire. Wires of different diams gave identical values. In the second method, a beam of light from an incandescent W sphere was focused through the flame on to the slit of a spectroscope. Na was introduced into the flame, and when the temp. of the flame was greater than that of the W sphere, bright Na lines showed up in a continuous spectrum background. If the temp were lower, reversal of the Na lines took place. By careful adjustment of the temp of the sphere, a point was reached when all trace of either bright or dark lines disappeared. This balance could be effected within a range of a few degrees. The corresponding temp. of the sphere was then detd. by means of an optical pyrometer. The results were independent of the thickness of the flame. Li gave the same results as Na, except that a thick flame from a 10-in. water-cooled burner was required for satisfactory work. Two flames at different temps. were measured individually and then superimposed and measured again. A mathematical formula was worked out which gave good agreement with the observed data. The apparent temp. of 2 superimposed flames differs markedly from the mean and is dependent on the relative positions of the flames. It would appear, therefore, that the method cannot be applied to estimate the av. temp. of a heterogeneous flame. The method is devoid of time lag and therefore may be of value in connection with internal-combustion engines, having already been tried with promising results. F. S. Granger

The initiation of flame in mixtures of carbon monoxide and oxygen. W. E. Garner

AND A. S. GOMM. Univ. of Bristol. *Trans. Faraday Soc.* **24**, 470–3(1928); cf. Garner and Johnson, *C. A.* **21**, 1059.—The rate of reaction of $2CO + O_2 \longrightarrow 2CO_2$ with an initial pressure of 0.3 cm —below the critical ignition pressure—was detd. at 750° in a quartz vessel with and without infra-red radiation. The infra-red had no appreciable effect on the reaction. For moderately dry and moist gases the crit. pressure of ignition is independent of temp. and is between 0.3 and 0.5 cm. for the range 660–850°. The rate of reaction for quartz surfaces is greater for moist than for dry gases. There is evidence that the reaction occurs in the gas phase at 850°. When the rate of surface reaction exceeds a certain value, a change is initiated into the gas phase, which is propagated as flame. ARTHUR FLEISCHER

Diffusion flames. S. P. BURKE AND T. E. W. SCHUMANN. *Ind. Eng. Chem.* **20**, 998–1004(1928).—Diffusion flames as distinguished from those of the Bunsen type which result from a premixing of air and gas, are defined as those in which combustible gas and air meet coincidently with the occurrence of combustion. On the basis of the following assumptions which are valid within limits, a mathematical theory of their behavior is presented: (*a*) the velocity of gas and air up the tube in the vicinity of the flame is const.; (*b*) the coeff. of the interdiffusion of the 2 gas streams is const.; (*c*) the interdiffusion is wholly radial; (*d*) the admixt. of the 2 streams occurs by diffusion only. Exptl. results are in excellent agreement with theory. H. L. OLIN

Bunsen flames of unusual structure. FRANCIS A. SMITH AND SAMUEL F. PICKERING. *Ind. Eng. Chem.* **20**, 1012–3(1928).—An abstract of a lecture illustrated with lantern slides showing unusual flame structures produced by varying combustion conditions, the causes for which have not been investigated. H. L. OLIN

Radiant energy from flames. W. E. GARNER. *Ind. Eng. Chem.* **20**, 1008–12 (1928).—Exptl. evidence relating to the character of emission from flames of CO is based on work involving the combustion of mixts. of CO with O_2, N_2 and H_2 in a closed tube with provision for the transmission of radiant energy through a fluorite window to a thermopile. In the case of the use of O_2 and N_2 the emissivity is definitely increased in spite of the lowering of temp. due to diln. With a 2% H_2 mixt. the radiation is diminished 7-fold. G. concludes that H_2 acts as a catalyst in the chem. sense at percentages above 0.2% and as a conserver of chem. energy within the flames up to 2%. This so called "*energo-thermic*" *catalysis* is brought about by collisions between protons or electrons and the newly formed products of combustion. H. L. OLIN

The flicker of luminous flames. D. S. CHAMBERLIN AND A. ROSE. *Ind. Eng. Chem.* **20**, 1013–6(1928).—The vibratory motion of luminous flames was studied by the photographic method and rate of vibration, speed of flame, movement and amplitude of vibration detd. for various gases under different conditions. The data show that the upper portion of the luminous zone rises to a max. height ten times per sec., and that this rate of vibration is not greatly affected by change in conditions. The lower portion of the flame has a continuous existence, but periodically gives off another flame, which rises above the main flame during its short period of existence. H. L. OLIN

Flame speed of hydrogen sulfide. D. S. CHAMBERLIN AND D. R. CLARKE. *Ind. Eng. Chem.* **20**, 1016–8(1928).—The speed of combustion of H_2S mixts. in a 2.5-cm. tube 1 m. long was detd. by means of the photographic method. The max. velocity was found to be 49.5 cm./sec. on burning 10.8% H_2S. H_2 is to a great extent oxidized selectively. Study of a continuous *method for producing* SO_3 by burning H_2S in an internal-combustion engine is proposed. H. L. OLIN

A colloid heat-indicator. RAPHAEL ED. LIESEGANG. Inst. physikal. Grundlagen der Medizin, Frankfort a. M. *Kolloid-Z.* **45**, 112–4(1928).—Certain alkaloids, when warmed with a sulfite soln., become turbid on account of the increase of alky. This reaction may be used to disclose the non-uniformity of temp. in the banded liquids described by Lloyd (*C. A.* **11**, 2532). J. H. PERRY

Measurement of e/m with a three-electrode valve with simultaneous measurement of its amplifying factor. DAULAT SINGH KOTHARI. *Indian J. Physics* **2**, 485–90 (1928).—Details are given of an arrangement by which the current in the anode circuit of a triode could be measured while known magnetic fields were applied by means of a Helmholtz coil. As the magnetic field was increased, the anode current at first remained almost const., then fell suddenly, and then decreased more gradually to zero. The computed results for e/m are much less than the accepted value. This is explained as due primarily to the effect of the grid. A method for computing the amplification factor from the exptl. results is discussed. W. W. STIFLER

Isotherms of monatomic substances and their binary mixtures. XXVI. Isotherms of helium at —183.0° and —201.5°, pressures from 3 to 8 atmospheres. G. P.

NIJHOFF AND W. H. KEESOM. *Verslag Akad. Wetenschappen Amsterdam* **36**, 1019–22 (1927).—Values are given for B_A of helium; they are compared with other detns. **XXVII. Isotherms of helium between —103.6° and —259.0° at pressures of 1.5 to 14 atmospheres.** G. P. NIJHOFF, W. H. KEESOM AND B. ILIIN. *Ibid* 1023–4.—Consts. for He were detd. at —103.29°, —146.50°, —224.94°, —235.77°, —249.80°, —252.57°, —255.845° and —258.99°. B. J. C. VAN DER HOEVEN

Isotherms of diatomic gases and their binary mixtures. XXXV. Isotherms of hydrogen at temperatures ranging from —225.5° to —248.3° and pressures running from 1.6 to 4.2 atmospheres. G. P. NIJHOFF AND W. H. KEESOM. *Verslag Akad Wetenschappen Amsterdam* **37**, 35–6(1928); cf. *C. A.* **22**, 2861.—pv_A has been measured for various pressures and compared with the theoretical values. From this it was calcd. that if the temps. are —225.54°, —231.52°, —236.56°, —241.84°, —248.32°, the corresponding values of $B_A \times 10^3$ are —0.268, —0.309, —0.340, —0.390 and —0.439. A. L. HENNE

Metal-metal oxide electrodes. F. J. WATSON. Imperial College of Sci. and Tech. London. *Chem. Eng. Mining Rev.* **20**, 172–5(1928).—Metal-metal oxide electrodes do not alter the compn. of the soln. and are well adapted for the continuous recording of p_H. They act well in the alk. region where quinhydrone is useless, though the p_H at which the hydroxide commences to be neutralized limits their use on the acid side. A calibration curve for each combination has to be established by comparison with the H electrode in a series of buffer solns. Applications of the W and Pt-Mn_2O_3 electrodes in the *sugar industry, control of boiler feed H_2O and treatment of sewage* are discussed. E. G. VANDEN BOSCHE

Recent investigations on cells contradicting the second principle of thermodynamics. VASILESCO KARPEN. *Compt. rend.* **187**, 418–20(1928).—The cells studied consisted of electrodes of Pt and C in solns. of NaOH. At high concns. C is pos. and becomes neg. at lower concns. With pure H_2O the e. m. f. is about 0.1 v. but there is no reaction to account for this. Values for $W = E_m - T_m \Delta E/\Delta t$ vary from —0.830 v. to —1.806 v. for the temps. 28° to 71° and 71° to 96°. E. G. VANDEN BOSCHE

The diffusion of a hydrogen potential or a reduction potential through platinum or palladium. REINHARD KÖHLER. *Z. physik. Chem.* **135**, 369–82(1928).—Expts. on Pt crucibles of from 0.05 mm. to 0.1 mm. wall thickness show that the H_2 potential produced on the outside by electrolytic pptn. at room temp. proceeds to the inside of the crucible only very slowly. The time necessary for a given change of the inner potential varies approx. with the square of the plate thickness, provided the potential change does not exceed 80 mv. The diffusion of H_2 through Pd only corresponded as a first approximation to the diffusion law, results agreeing with Nernst and Lessing. The effect of the reduction potential on the diffusibility was studied with thin Pd plates (0.02 mm.) for $CrCl_3$, K cobalticyanide, NH_4Cl-$FeSO_4$, $SnCl_2$, hydrazine, Na_2S, $K_3Fe(CN)_6$, $FeSO_4$, $FeCl_2$, pyrogallol and hydroxylamine. The diffusion effect is in general greater the greater the reduction potential calcd. from the N H-ion concn. M. R. FENSKE

The reduction potential of cysteine. L. MICHAELIS AND L. FLEXNER. *Naturwissenschaften* **16**, 688–90(1928).—Cysteine-cystine mixts. do not show an ordinary reduction-oxidation potential, depending on relative concn. and p_H; the system is not a reversible one. However, Dixon and Quastel's observations of a potential $E = E_0 + (RT/F \ln [H^+]/[\text{cysteine}])$ on solid gold electrodes if measured rapidly were confirmed, E_0 varying more than 50 milliv., depending on the individual gold electrodes. For Hg electrodes E_0 was 200 milliv. more negative. They explained it by the inability of cystine to take up H from the metal and difference in H overpotential of the latter. It was now found that on careful removal of traces of O the reduction potential of cysteine is equal for Pt, gold-plated Pt and Hg electrodes. Solid gold is the only abnormal metal; it gives false equilibria. The establishment of equil. takes for Pt several hrs., longer even for Au, shorter for Hg. N_2 or H_2 atm. does not influence the value of the potential. The O was removed from the soln. by passing through purified (Cu at 600°) N_2 excluding rubber tubing. O_2 addn. of 1:40,000 upset the equil. on Pt, giving a more positive potential. The D. and Q. equation was found to hold, E_0 being —0.001 v. relative to the normal H electrode at 38°, accuracy ±0.002 v. The concn. range examd. was for cysteine 0.1 to 0.0002 M, p_H from 2 to 8. No explanation of the effect is offered. B. J. C. VAN DER HOEVEN

The electrokinetic potential between the solid and liquid states of a single substance. FRED FAIRBROTHER AND FRANK WORMWELL. Univ. of Manchester. *J. Chem. Soc.* **1928**, 1991–7.—The production of an elec. charge by the friction of a liquid against the same substance in the solid state was investigated by a cataphoresis method.

The movement of a small rod of the solid suspended in the liquid at a temp. within a few degrees of the melting point and between 2 Pt electrodes was measured with a microscope. The solid was found to be positively charged in all cases except in C_6H_6 and o-ClC_6H_4OH, in which cases no deflection could be observed. Substances showing deflections were H_2O, AcPh, $PhNO_2$, guaiacol, anethole, o- and p-$CH_3C_6H_4OH$ and o-$C_6H_4ClNO_2$. The deflection is greatest in H_2O and AcPh. The authors conclude that it is only with polar compds. that the effect is observable, and that it is greater the more polar is the substance. If, according to Coehn's rule, the phase with higher dielectric const. should become positively charged, the results agree with the work of Errera (*C. A.* **22**, 2305) in that the dielectric const. of a polar substance is higher in the solid state than in the liquid state. H. F. Johnstone

Alteration in the galvanic potential of metals, in color and in resistance of gold-silver-copper alloys on cold working. G. Tammann and C. Wilson. Göttingen Univ. *Z. anorg. allgem. Chem* **173**, 156–63(1928).—Hard metals are generally less noble than when soft, though in 2 out of 9 cases the reverse was true. If the p. d. between a hard and a soft piece of metal is due to the difference in the condition of the outer surface then when the externally hardened surface of the metal rubbed with emery is removed by soln., zero e. m. f. is to be expected. This was found to be the case. Heating a piece of Cu which had been rubbed with emery removes the potential due to the less noble surface. Cold working such alloys as are characterized by certain colors renders them more yellow. On reheating, the color disappears and at the temp. of heating the elec. resistance also diminishes and whiter tones ensue. S. L. B. Etherton

The conductivity and p_H values of mixtures of acids in solutions. J. A. Cranston and J. Duncan. *J. Roy. Tech. Coll. Glasgow* **4**, 41–7(1927).—A study of the changes in p_H and elec. cond. accompanying the replacement of water in a HCl soln. by acetic, citric, tartaric, oxalic and phosphoric acids. As the concn. of acetic, citric and tartaric acids in the soln. increases, the elec. cond. decreases but the H-ion concn. detd. by the e. m. f. method increases. In the case of the other 2 acids this effect is not so marked. The influence of the concn. of the HCl is also studied. If H_3PO_4 is added to solns. of HCl greater than 1 *N*, decrease in cond. results. If the HCl is less than 1 *N*, the cond. increases with addn. of H_3PO_4. These effects are discussed briefly along with the meaning of the terms "viscosity" and "concn. of ions" R. E. Gibson

Electrical conductivity of solid sulfide mixtures. P. Fischer. *Z. Elektrochem.* **33**, 571–7(1927).—Following work on mixtures of salts and of oxides (*C. A.* **20**, 2276; **21**, 693), the elec. cond. of compressed mixts. of powdered sulfides has been detd. for direct and for a. c. at various temps. For mixts. of two sulfides the cond. does not vary in a simple manner with the percentage compn. of the mixt. With Ag_2S and PbS the cond. increases with increasing proportion of PbS, but eventually reaches a max. at about 90% PbS. Although the cond. of Ag_2S is essentially electrolytic and that of PbS electronic, migration expts. on a 50% mixt. indicate that only about 1% of the cond. is electrolytic. For mixts. of Ag_2S with FeS, which is practically a non-conductor, the cond.-compn. curve exhibits a min. and a max. Mixts. of FeS and PbS are practically non-conducting up to 50% PbS, but with higher proportions the cond. increases rapidly. Mixts. contg. sulfides of Cu, Zn, Cd and Ba were also examd. It appears that the type of cond. exhibited by a solid substance may be modified by certain conditions. The observed phenomena are attributed to distortion of the crystal lattices and electron orbits as a result of compression. B. C. A.

Electrical conductivity in solid sodium chloride at room temperature. J. Gingold. *Z. Physik* **50**, 633–43(1928).—G. tested natural crystals produced by cleavage, artificially grown crystals and pressed pastilles for cond. and for charging and discharging currents as condensers. For const. potential in each case the cond. decreases with time. The phenomena are best explained by assuming that current passage requires spatial deformation of crystal lattice to permit ionic movement. A perfect crystal lattice such as is most nearly approached in the natural crystal is most difficult to deform and accounts for initially low and decreasing cond. Artificially grown crysts. contain more imperfections and hence show greater cond. A. P. Sachs

The electrical conductivity of tellurium and of liquid mixtures of tellurium and sulfur. Charles A. Kraus and Ernest W. Johnson. Brown Univ. *J. Phys. Chem* **32**, 1281–93(1928).—The purpose was to det. the influence of varying amts. of the nonconductive S on the elec. cond. of the highly conductive metallic Te. *Special types of cond. cells for measuring the resistances of liquid mixts. at high temps.* as well as a *const.-vol. gas thermometer* for use as a high-temp. regulating device are described. The log of the sp. resistance decreases approx. linearly as the temp. increases for mixts. of Te and S as well as for pure Te. The values for the sp. resistance at 400° for several

mixts. are as follows: Pure Te, 6.41×10^{-4}; 5 at. % S, 8.910×10^{-4}; 15 at. % S, 5.741×10^{-3}; 30 at. % S, 2.390×10^{-1}; 50 at. % S, 1.571×10; 70 at. % S, 1.870×10^{3}; 85 at. % S, 2.317×10^{5}. Beginning at 30 at. % S and at higher S concns., polarization effects become marked, indicating the presence of ordinary ions. The ionization of Te diminishes rapidly with increasing S content. The metallic properties due to Te are evidently lost when the no. of S atoms in the mixt. becomes equal to, or slightly greater than, the no. of Te atoms. The sp. resistance of liquid Te at its melting pt. is about $^1/_{16}$ that of solid Te at the same temp.; at 500° the value for the former is about $^1/_6$ that of Hg at ordinary temps. H. F. JOHNSTONE

Electrical conductivity of palladium in a vacuum and in different gases. A. PUODZIUKYNAS. *Z. Physik* **46**, 253-70(1927).—The cond. of untreated Pd wire increases by about 15% when the gas contained in the metal is removed by ionic bombardment in a vacuum; the increase in cond. was proportional to the amt. of gas removed, and the total amt. of gas evolved was approx. 300 times the vol. of the wire. After treatment for 50 min. at bright red heat in pure H the cond. fell by 50% and 1486 vols. of gas were absorbed. When the wire was maintained in H at 1 atm. its cond. rose slowly, and more rapidly if the wire was in a vacuum until about 900 vols. of gas had been evolved; this indicates that after glowing in hydrogen the metal is supersatd. with H. When the gas is removed by heating in a vacuum the wire absorbs H slowly and N not at all; if, however, the gas is removed in the cold the wire becomes activated and absorbs approx. the same amt. of N or H. B. C. A.

The electric conductivity of kerosene and gasoline as a function of the temperature. C. A. MOREHOUSE. Ia. State Col., Ames. *Proc. Iowa Acad. Sci.* **34**, 271-2(1927), cf. *C. A.* **20**, 333.—Kerosene was put into a glass cond. cell heated by a home-made heating coil. This cell was connected in series with an electroscope. The electroscope was then charged through the kerosene by means of an electrophorus and the time required for the leaf to fall through 10 divisions on the scale was taken by means of a stop-watch. This arrangement worked very satisfactorily for the kerosene. A curve is plotted which shows that the resistance of the kerosene decreases steadily with a rise in temp. resulting in the following equation of consts.: $R_t = 290.53\ (1 - 0.0161t + 0.000068t^2)$. In applying this method to gasoline the resistance was so low that the deflection of the leaf was too rapid to be measured with a stop-watch. But by charging a condenser through gasoline and then discharging it through a galvanometer it was found that its resistance decreases very rapidly with an increase of temp.

W. G. GAESSLER

The theory of superconductivity. L. KORDYSCH. *Ukrainische Phys. Abh.* **1**, 56-69(1926); *Phys Ber.* **8**, 931(1927).—The ohmic resistance R arises from the opposing action of ions on each other, and the magnetic component of resistance may be neglected. The energy of the electromagnetic field is related to electron displacement. The supercond. begins when the probability η_1 that an electron is captured by a given ion is zero. The self-induction L_1 and η are related by $L = m/[e^2N(1 - \eta)]$, where e is the charge and m the mass of the electron and N is the Loschmidt no. The sp. cond. σ is given by $\sigma = {}^1/_2(e^2/m)\ (1 - \eta)/\eta$. The dependence of η on T is given by $\eta = kT/3bm$. G. L. CLARK

Electromotive force due to friction between various metals. A. LAFAY. *Compt. rend.* **186**, 133-4(1928); *Science Abstracts* **31A**, 404.—When one metal is rubbed on another their point of contact becomes the seat of an e. m. f., due partly to the contact of the two metals and partly to the rise of temp. caused by the friction. The two effects are usually in opposition, and the effect due to heat can easily be eliminated or allowed for. By giving one of the metals the form of a disk rotated at a known speed, and pressing the other metal on the rim of the disk, it is found that the e. m. f. produced is proportional to the relative speed of the two substances and is independent of the pressure which keeps them in contact. If the relative speed is V, then for speeds between 0 and 8 m. per sec. the e. m. f. of friction between Ag and polished steel is $8 \times 10^{-3}V$ v., and that between Cu and steel is $0.16 \times 10^{-3}V$ v. Also for a given value of V the e. m. f. observed is unaltered for a variation of pressure between 10 and 200 g. per sq. mm. H. G.

The reduction of oxygen at the dropping mercury cathode. J. HEYROVSKÝ. Charles Univ., Prague. *Časopis Československého Lékárnictwa* **7**, 242-51(1927).—With the polarographic arrangement and by means of the dropping Hg cathode, the elec. reduction of atm. O_2 dissolved in aq. solns. can be followed in a quant. manner. The expts. carried out with dil. solns. of electrolytes, exposed to the air, lead to the following conclusions: (1) O_2 is first reduced to H_2O_2 at a potential equal to about that of normal Hg_2Cl_2 electrode, the influence of p_H upon this reduction potential being very small,

(2) the second stage is the elec. reduction to H_2O; this occurs at a 0.001 *N* concn. of H ions at a potential of —0.60 v. and is shifted to more negative values according to the formula $(RT/4F)\log[O_2].[H^+]^4$; (3) a quant. detn. of the content of O_2 and H_2O_2 in solns. may be made from the dimensions and positions of waves on the polarization curves; (4) well-pronounced maxima due to interfacial absorption of O_2 are shown on the current-voltage curves; these may be suppressed by small addns. of surface-active matter (*e. g.*, sulfosalicylic acid and org. dyes) or by high concns. of electrolytes.

WILLIAM J. HUSA

Electromotive force of flowing (aqueous solutions in glass tubes), and stability of colloids. II. H. R. KRUYT AND P. C. VAN DER WILLIGEN. Utrecht Univ. *Kolloid-Z.* **45**, 307–19(1928).—K. and W. take as a measure of the capacity for various electrolytes to ppt. colloids, the e. m. f. set up by the flow of their soln. through a glass capillary. In the alkali series, the capacity increases from Li^+ to Cs^+, and that of $MgCl_2$ is greater than that of $BaCl_2$. HCl is about as effective as $BaCl_2$. Of the following tervalent ions: Ce, La, $Co(NH_3)_6$ and Al, the last produces the same e. m. f. at about one-hundredth of the concn. of the others. This is not caused by hydrolysis. $ThCl_4$, Pt^{+4} and 2 Co complexes, quadrivalent and sexivalent, were also tested. The e. m. f. of K is not affected by the anion, except in the case of OH, which raised the e. m. f. greatly. KOH shows the same increase in quartz and in Jena glass capillaries. The difference in e. m. f. of the various ions is attributed to differences in the charge of hydrated ions. The e. m. f. of pure H_2O could not be detd. because it is affected by too many factors.

G. CALINGAERT

Oxidation-reduction potentials of the pentacyano-ferroates. DAVID DAVIDSON. Stanford Univ. *J. Am. Chem. Soc.* **50**, 2622–30(1928).—The oxidation-reduction potentials (against the *N* Hg_2Cl_2 electrode) of the following salt mixts. in *N* KCl at 21° were: $K_4Fe(CN)_6$-$K_3Fe(CN)_6$, 0.198 v.; $Na_3Fe(CN)_5.NH_3$-$Na_2Fe(CN)_5.NH_3$, 0.092 v.; $Na_3Fe(CN)_5.H_2O$-$Na_2Fe(CN)_5.H_2O$, 0.209 v.; $Na_4Fe(CN)_5NO_2$-$Na_2Fe(CN)_5$-NO, 0.231 v. Variations of potentials from the theoretical electrochem. law indicated the formation of the compd. *2$Na_2Fe(CN)_5.H_2O$.3$Na_3Fe(CN)_5.H_2O$.* D. D.

Electrometric titration curves for dibasic acids. I. Normal acids. RICHARD GANE AND CHRISTOPHER KELK INGOLD. Univ. Leeds. *J. Chem. Soc.* **1928**, 1594–1600.—The purpose was to test by some phys. method the hypothesis that the angles between the valences of a C atom are modified by the space requirements of the attached groups. The method of dissocn. consts. of acids was used and the formulation of Bjerrum was adopted to give *r*, the distance between the ionizing groups. By the method of Auerbach and Smolczyk (*C. A.* **19**, 222) the 2 dissocn. consts. were obtained. The acids studied were of the type $CO_2H(CH_2)_n.CO_2H$, from oxalic to azelaic. For the acids from glutaric to azelaic the equation $r = 4.4 + 1.73n$ closely approximates the observed values. The increase per methylene group in the length of the C chain is then about 1.73 A. U.

M. R. FENSKE

The determination of sodium-ion concentration by a sodium amalgam electrode. G. ETTISCH AND K. JOACHIMSOHN. Kaiser Wilhelm Inst., Berlin. *Z. Elektrochem.* **34**, 404–6(1928).—Describes an electrode vessel for use with alkali metal amalgams in cells of the type, *X* amalgam | *X* salt soln. | satd. KCl | Hg_2Cl_2 electrode. The article gives full details with illustrations and also describes an app. for prepg. pure amalgams. An attractive feature is the good use made of ground-glass joints for connecting the various pieces of app. The electrode was tested with Na and NaCl and the observed and calcd. results agreed most satisfactorily.

R. E. GIBSON

The relation between current density and current efficiency in the process of persulfate formation. O. A. ESIN AND E. I. KRUILOV. *Ann. inst. polytech. Oural* **6**, 221–30(1927); cf. *C. A.* **21**, 1935.—Further expts. fully confirm the earlier results of the author.

G. B. KISTIAKOWSKY

The oxidation potential of the quinquevalent-tervalent columbium system. II. SAMUEL J. KIEHL AND DAVID HART. *J. Am. Chem. Soc.* **50**, 2337–45(1928).—The oxidation potentials of the Cb^V-Cb^{III} system were measured with a Hg electrode in an atm. of H at 25°. The av. normal electrode potentials, calcd. from the relation $E = E_0 - 0.0295 \log [Cb^{+++}]/[Cb^{+++++}]$ for the 3 concns. of H_2SO_4 used were —0.3730, —0.3849 and —0.4261 v.

H. R. MOORE

Investigations on the electrolytic oxidation of organic compounds. C. MARIE AND G. LEJEUNE. *Compt. rend.* **187**, 343–4(1928).—In oxidizing alcs. with a Ni anode and in alk. medium, there is but slight depolarization and electrolysis begins at 1.5 v. With Au and H_2SO_4 the result is similar, but with Au and NaOH electrolysis begins at 1.1 v. and after a short time rises to 1.6 v. With Pt and NaOH electrolysis begins at 0.7 v., stops and begins again at 1.6 v. With Pt in acid medium it begins

at 0.7 v., stops and begins again at 1.1 v. To limit the oxidation of the alc. to aldehyde, the lower values should be maintained. This is done by increasing the alc. concn. or by slight interruptions in the electrolysis. E. G. VANDEN BOSCHE

Metal overvoltage measurements with the cathode-ray oscillograph. EDGAR NEWBERY. Univ. of Capetown. *Proc. Roy. Soc.* (London) **A119**, 680–6(1928); cf. *C. A.* **11**, 2640; **21**, 1405.—N. has repeated his measurements of metal overvoltage using the cathode-ray oscillograph in an effort to check his previous results and hence meet the objections to his previous work with the rotating commutator, and has also provided further data for the soln. of the problem of the origin of transfer resistance. Electrodes of Cu, Ag, Zn, Cd, Hg, Pb, Fe, Ni and Co were used with normal solutions of the corresponding sulfates except for Ag, Pb and Hg with which the nitrates were used. A metal overvoltage of nearly zero was obtained for the first 4 metals, checking previous results He concludes that when only metal is being deposited there is no metal overvoltage and no transfer resistance. Entirely different results were obtained for the overvoltage of Fe, Co and Ni These correspond in magnitude to that of a soln. of acid where H_2 is deposited, therefore, the overvoltage measured is that of H_2 and not that of the metal. This is assumed to be due to hydration of the ions of these metals. A. J KING

The effect of hydrogen-ion concentration on overpotential. F. P. BOWDEN. Lab. of Phys. Chem Cambridge, England. *Trans Faraday Soc.* **24**, 473–86(1928) —The overpotential of H ions was detd. for buffered and unbuffered solns in which there was no dissolved O_2 at current densities from 10^{-8} to 10^{-3} amps /sq. cm. By plotting the overpotential against the log of the c. d. the curves obtained were for each soln 2 straight lines with the break at about an overpotential of 0.9 v. Part 1 of the curve was the same for all solns., showing that in this range of current densities, the overpotential was independent of the H-ion concn. The slope is about 0.120 and the equation of the line is $\eta = a_1 + b \log i$, where η is the H overpotential and i is the current density. For part 2 the overpotential increases with decreasing H-ion concn., the shift being about 58 millivolts for every tenfold decrease in the H-ion concn. The primary process in part 2 is the deposition of H ions, since the shift is dependent only on the H-ion concn and not on the compn. of the soln. In dil. unbuffered solns the observed shift in overpotential is greater than calcd., probably because of concn polarization. The equation for part 2 lines is $\eta = a_2 + 2b - \log i$ The slope is about 0 220. Frequently the c d may be reduced when above the break without reverting to slope 1. The disagreement between various authors is probably due to their being on the 2 different lines The exptl. work was checked by detns. with a dropping cathode, the c d. and overpotential being taken at the largest size of the drop. There is no special significance to the terms "hydrogen deposition potential" and "minimum potential." A F.

The method of current density-voltage measurement. ARMIN DADIEU. *Z Elektrochem.* **34**, 301–5(1928).—A discussion of the standard method of c. d.-voltage curves as applied to decompn. potential of fused salts and non -aq solns It is shown that in many instances it is preferable to det. the c. d.-voltage curve in the direction of decreasing c. d. By this means breaks in the curve due to unstable or complex electrode products are avoided and more dependable values of the decompn. potential are obtained. The advantages of this method are: (1) in cases where the normal method affords no exact values of the decompn. point, exact values can be obtained; and (2) in cases where a metal fails to deposit in the normal manner the conditions of this method sometimes make the deposition possible; and (3) fewer points need to be detd. W. J. SWEENEY

The theoretical potential of the alkaline earth metals. G. DEVOTO. Ist. chimica industriale, Milano. *Z. Elektrochem.* **34**, 19–22(1928).—The standard potential M^{++}/M has been calcd. thermodynamically for M = Ca, Sr, Ba and Mg. The values are 2.897, 2.945, 2.956 and 2.353 v., resp., in good agreement with the expts. of Cambi and Devoto with molten salts (*C. A.* **21**, 2837; **22**, 1716). A. L. HENNE

The extrapolation of electromotive force measurements to unit ionic activity. DAVID I. HITCHCOCK. Yale Univ. *J. Am. Chem. Soc.* **20**, 2076–9(1928).—With a partially expanded form of the Debye-Hückel equation, namely,—$\log \gamma = 0.5\,m - Bm$, where B is an addnl. const., e. m. f. *versus* molality curves are obtained which deviate from straight lines only slightly above $0.02 \cdot M$. The extrapolated E_0 values for HCl at 20°, 25° and 30° are 0.2253, 0.2223 and 0.2193 v., resp. This method checks with all data except those for 25° below 0.003 M. H. R. MOORE

The theory of passivity phenomenon. II. The relation between passivity, current density and time. WOLF JOHANNES MÜLLER AND OTTO LÖWY. Techn. Hochschule, Wien. *Monatsh.* **49**, 46–74(1928); cf. *C. A.* **22**, 3090.—The formula $t_p = B(i_0)^{-m}/(F_0)$

is obtained from the theory of covering polarization and gives a straight line when the passivity time and the c. d. are plotted logarithmically. The earlier work of W. J. Muller (*C. A.* **22**, 347) giving values of the passivity time and av. c. d. for Fe, Ni, Zn, and Cr shows that this relationship is in good agreement for these 4 metals. Accurate investigations with Fe in different electrolytes at const temp. show that this relationship is valid for H_2SO_4 contg. ferrous-ferric sulfate as well as for *N* H_2SO_4. Studies with freely suspended and rotating electrodes give the theoretically expected effect. In electrolytes satd. with $FeSO_4$, passivity began first on the freely suspended electrode at a somewhat higher c d. than for the protected electrode and the passivity time was longer than for the protected electrodes. At higher c. ds. the time interval was less.
M. R. FENSKE

The electron theory of metals according to the wave mechanic statistics, especially as applied to the question of the Volta effect. A. SOMMERFELD. *Ber.* **61B**, 1171–80 (1928).—An address before the Deut. chem. Gesellschaft, presenting in a somewhat popular form the significance of the new wave-mechanics theory. Special prominence is given to the new results by G. P. Thomson, showing that cathode rays produce interference patterns by passing through metal foil or celluloid exactly like the diffraction patterns obtained with x-rays. Metals occupy an especially interesting place since the existence of free electrons is involved It is established according to recent calcns that in the close packing of metal atoms the outer electrons assume an unstable condition and become loosened from the mother atom In this way it may be predicted which atoms will possess metallic character in the solid state. In order to understand the properties of the free electrons in the interior and on the surface, the newest wave mechanics theories are used. These methods describe the statistical properties of the electrons in as complete and simple a fashion as the wave theory of light explains the phenomena of optics and x-rays. It is most promising that these most recent phys. theories have such valuable and useful chem. applications. G. L. CLARK

The magnetic double refraction of liquid mixtures. G. SZIVESSY AND M. RICHARTZ. Univ. Munster. *Ann. Physik* **86**, 393–421(1928).—The magnetic double refraction of 13 different binary mixts. was detd as a function of the vol. concns. of the components The observed values are uniformly smaller than those predicted from Langevin's orientation theory. H. R MOORE

The theory of the Kerr and Faraday effects in gases. II. The quadratic effect. R DE L. KRONIG. *Z. Physik* **47**, 702–11(1928).—Using the method of *C. A.* **22**, 521 and extending it to cover the quadratic terms in the effect, equations are derived giving the Kerr and Faraday effects for diatomic mols , in terms of the quantum number of the absorption bands and known consts The equations agree in form with the empirical equations. They predict in agreement with expt. no linear Kerr effect. They agree in order of magnitude with measured values for the Faraday effect the small discrepancy being due, it is supposed, to the neglect of the continuous absorption of gases used. A new, simple relation between the Verdet const. for the Faraday effect and the Kerr const. is derived. Exptl. data are as yet not available to check this relation. F. R. B.

The dielectric constants of binary mixtures. VII. The electric moments of certain diphenyl derivatives. Their relation to the several structures. JOHN W. WILLIAMS AND ARNOLD WEISSBERGER. Leipzig Univ. *J. Am. Chem. Soc.* **50**, 2332–6(1928); cf *C. A.* **22**, 1528.—The elec. moments of derivs. of diphenyl as well as *p*-phenylenediamine are detd from dielec. const. and d. data of dil solns. at 25°. The elec. moments of *p*-dichlorobenzene, 4,4′-dichlorodiphenyl, *p*-dinitrobenzene and 4,4′-dinitrodiphenyl are zero, but the introduction of single Cl or NO_2 groups results in highly unsymmetrical mols. with high elec. moments. For the dinitro and dihydroxy derivs. the data suggest an open or extended structure of the benzene nuclei, while in the amino or benzidine type the rings are folded. **VIII. The electric moment as a vector quantity.** JOHN W. WILLIAMS. *Ibid* 2350–7.—Dielec. and d. data have been obtained for various derivs. of benzene, contg pos. substituents such as CH_3, and neg. as OH and NO_2. These substituent atoms or groups may be considered as vectors acting in certain directions. For di-substituted compds. the resultant moment is to a certain extent calculable from the formulas of Thomson (*C. A.* **18**, 17) on the assumption of no interaction between the 2 groups. Good agreement is obtained for mols. with simple substituents, while the disparity shown with the heavier and more complex radicals suggests the need of 3 dimensional diagrams permitting interaction between the various groups. The data support the plane formula for the *benzene mol.*
H. R. MOORE

Dielectric constants of solutions of electrolytes. H. HELLMANN AND H. ZAHN.

Z. physik. Chem. **132,** 399–400(1928).—Polemical (cf. Walden, Werner and Ulich, *C. A.* **22,** 1718). H. G.

Dielectric constants of electrolytic solutions. H. Hellmann and H. Zahn. *Ann. Physik* **86,** 687–716(1928); cf. preceding abstract.—This is a detailed reply to a series of articles of similar title by P. Walden, H. Ulich and O. Werner (cf. *C. A.* **22,** 1718). The resonance method and various exptl. details are discussed critically at considerable length. W. W. Stifler

Dielectric constants and absorption indices of ethyl alcohol for short electric waves. San-Ichiro Mizushima. Tokyo Imp. Univ. *Proc. Imp. Acad.* **4,** 205–7(1928).—The dielec. const. and absorption index of EtOH were detd. between —60° and 60° by the resonance method, using elec. waves of wave length 59 cm. These and previous results for other wave lengths show that the region of anomalous dispersion is shifted toward longer wave lengths as the temp. is lowered. This agrees with Debye's dipole theory. From the exptl. values for the dielec. const., and by making use of Debye's formula, the mol. radius can be calcd. It is found to be 2.1×10^{-8} cm., which is in good agreement with the value obtained by other methods. C. J. West

The relation between the dielectric constant of helium and the temperature. M. Wolfke and W. H. Keesom. Univ. Leiden. *Verslag Akad. Wetenschappen Amsterdam* **37,** 533–9(1928); cf. *ibid* **36,** 1204(1927).—The measurements of the dielec. const. of liquid He were made in the app. previously described and improved on. The break in the $\epsilon - T$ curve is at 2.295° abs. and 38.65 mm. pressure for the triple point of liquid helium I and II with vapor. At that point the ϵ value found is 1.05594. From Onnes and Boks' values for the d. of liquid helium the polarization of liquid He between 2.05° and 4.19° abs. is calcd. by the Clausius-Mosotti equation to be 0.1241 to 1.1253, av. 0.1246, *i. e.*, practically const. and the same for I and II. From optical data on He gas follows for the polarization of the latter 0.1292. It is concluded that the He mol. in liquid I and II and in the vapor is the same. B. J. C v. d. H.

Thermal variation of magnetic rotatory power when the magnetization coefficient is positive and independent of temperature. H. Ollivier. *Compt. rend.* **186,** 1001–3 (1928).—Paramagnetic substances may be classified according as they obey Curie's, Weiss', or other similar laws, or have paramagnetism independent of the temp. Becquerel showed that, according to Langevin's theory of the orientation of paramagnetic atoms in a field, paramagnetic rotation of the plane of polarization occurs, which is proportional to the coeff. of mass magnetization. Assuming the simple additive law expressing this in terms of Verdet's constant, the variation in magnetic potential, and the observed rotation, it is shown for $Na_2Cr_2O_7$—a compd. shown by Weiss and Collet (*C. A.* **20,** 1170, 2781) to have a constant paramagnetism—that Verdet's const (referred to unit mass) is independent of temp. between 7° and 61°. A soln. of I-free ZnI_2 (d^0 2.482) was found preferable to CS_2 as a comparison substance. It has a Verdet const. 1.36 times as great at 16°, with yellow or Hg green light. It is transparent up to $\lambda 0.3\mu$ B. C. A.

Theory of ferromagnetism. W. Heisenberg. *Z. Physik* **49,** 619–36(1928).—An attempt is made to explain the Weiss mol. field on the basis of a quantum mechanics energy-interchange process similar to that recently applied by Heitler and London to the interpretation of homopolar valence forces. According to this, ferromagnetism is possible only (1) when the lattice is such that each atom has at least 8 neighbors, and (2) the principal quantum no. of the electrons responsible for the magnetism must be $\lesssim 23$. These conditions together do not serve to distinguish Fe, Ni and Co from all the other materials but Fe, Ni and Co satisfy these conditions. The present paper is therefore regarded by H. as preliminary and further development is promised. W. W. Stifler

The magnetic susceptibility of the iron salts from Wildbader thermal waters and other mineral springs. Gaisser. *Metallbörse* **17,** 1603; *Chem. Zentr.* **1927,** II, 1462.—A proof for the magnetic susceptibility of the Fe salts is the reaction with benzidine-HCl and H_2O_2. G. does not recommend the use of these reagents to detect catalytic action of waters since various definitely catalytic waters do not give the reaction. The p_H is important for successfully carrying out the reaction. When it becomes too high the reaction becomes negative. The mountain springs at Cannstadt and the brook springs at Teinach gave positive reactions. All other springs which were investigated gave negative reactions. J. S. Reichert

Application of thermomagnetic analysis to the chemistry of iron. J. Huggett, H. Forestier and G. Chaudron. *Chimie & industrie* Special No., 588–91(April, 1928).—The previously described (*C. A.* **20,** 1939) app. for thermomagnetic analysis has been modified so as to permit recording the displacement of the luminous spot

The possible applications of the instrument are discussed by reviewing the results obtained with it to date (*C. A.* **20**, 1939; **21**, 1218; **22**, 1934). A. P.-C.

The magnetization of single crystals of nickel. SEIJI KAYA. *Sci. Repts. Tôhoku Imp. Univ.*, 1st ser., **17**, 639–63(1928); cf. *C. A.* **22**, 907.—Crystals of electrolytic Ni 7 cm. long and 2.3 cm. in diam. were prepd. by moving a long crucible, contg. molten Ni, out of the furnace as slowly as the metal froze. They were filed into the form of oblate ellipsoids with the equatorial planes parallel, resp., to the 3 planes (100), (110), and (111). The magnetization curves in various directions through the crystals are illustrated and discussed. The permeability was much increased by annealing. The crystals appeared isotropic up to a magnetization intensity of 205, but above that, the magnetizability decreased from the trigonal to the digonal to the tetragonal axes. The parallel and perpendicular components of magnetization for a const. field varied periodically in a given plane according to the form of space-lattice. The amplitude of this variation was greatest in the (110) and least in the (111) plane. G. F. C.

Determination of the magnetic saturation of iron carbide. F. STÄBLEIN AND K. SCHROETER. *Z. anorg. allgem. Chem.* **174**, 193–215(1928).—A ballistic method for finding the satn. value of the intensity of magnetization is described in detail, including the calibration of the app. and the exptl. detn. of the various corrections necessary. A large Weiss type of electromagnet was used to furnish the necessary fields. A preliminary investigation was made with pulverized specimens for which the satn. values had already been detd. in solid form. The results indicated that the method could be relied upon for powders. Fe_3C was prepd. from pig Fe by soln. in 0.1 *N* cold H_2SO_4. Tests on this gave 12,400 gausses as the satn. value for $4\pi J$, where J is the intensity of magnetization. By extrapolation from 2 specimens of C steel contg. 0.46% and 0.95% of C, resp., an av. value of 12,300 gausses was obtained. S. and S., therefore, conclude that the most probable value for satn. is $4\pi J = 12{,}350$ gausses. W. W. S.

Magnetic properties of cobalt. MARGARETE SAMUEL. *Ann. Physik* **86**, 798–824 (1928).—Two specimens of Co, approx. 18 cm. long and 0.8 cm. in diam., were studied by the magnetometric method. One contained approx. 1.33% Fe, the other 1.5% Fe; both contained traces (less than 0.1%) of C, Mn, Ni and Si. The usual magnetization curves, ideal magnetization curves, reversible permeability and coercive force as a function of the temp. between —185° and 400° are given for each specimen. In spite of careful preliminary annealing, the results for the 2 specimens are not in agreement. At $H = 700$ gausses one gave 773 as the magnetization while the other gave 1086. Similarly, although in each case the reversible permeability decreases with increasing magnetization, for one specimen the values lie between 24 and 9, while the corresponding limits for the other are 86 and 6. Contrary to the observations of O. Bloch that heating Co above 700° produces magnetic hardening, S. found no appreciable alteration in magnetic properties after heating to 1000°. However, in one of the specimens a distinct magnetic hardening was observed after chilling in liquid air. The Gans law of magnetic corresponding states does not seem to hold for these specimens.
W. W. STIFLER

Magnetic susceptibility of ozonides. V. I. VAIDYANATHAN. *Indian J. Physics* **2**, 421–33(1928); cf. *C. A.* **21**, 1921.—The magnetic susceptibilities of 5 typical ozonides were measured by a modified Curie balance. The special precautions made necessary by the explosive nature of the ozonides, both in their prepn. and during the measurements, are described. All were found to be diamagnetic. The susceptibility of the O_3 mol., computed from the exptl. results on the assumption of the validity of Pascal's additive law, is approx. -25×10^{-6} per g. mol. The electron arrangement in the O_3 mol. is discussed at some length and a possible structure for it is suggested which leads to results in general agreement with those obtained experimentally. W. W. S.

Magneto-electrolytic potentials. EDWARD O. HOLMES, JR., AND ALDEN HANDY. *J. Am. Chem. Soc.* **50**, 1303–14(1928).—An enlargement on the work of Scarpa shows that in solns. of electrolytes flowing through magnetic fields a potential difference is developed at right angles to the direction of flow and that of the field. The potential difference is independent of the concn. and nature of the dissolved electrolytes, but proportional to the linear velocity and to the field strength. A theoretical discussion of the data from osmotic and dynamo viewpoints is presented, and an equation derived. The possibilities of ionic displacement and induced ionization are discussed.
W. J. SWEENEY

The application of theoretical chemistry to some of the important processes in the production of steel. HERMANN SCHENCK. *Archiv. Eisenhüttenwesen* **1**, 483–97(1928).—A theoretical paper dealing with applications of theoretical chemistry in the production of steel. A discussion is given of the manner in which chem. reactions are influenced

thermodynamically by using for an example the equil: $2CO \rightleftharpoons CO_2 + C$. In considering dephosphorization and Mn combustion in the furnace, the mass-action law is used. Thus is deduced the expression:

$$(P_2O_5) = \frac{(\Sigma P_2O_5)}{1 + \frac{(FeO)^3}{D_1} + \frac{(MnO)^3}{D_2} + \frac{(CaO)^3}{D_3} + \frac{(MgO)^3}{D_4} + \ldots\ldots},$$

(D = equil. const. for the dissocn. of the phosphate and silicate), giving P_2O_5 in terms of (ΣP_2O_5) and the free basic components. In like manner the total MnO content is detd.:

$$(\Sigma MnO) = \frac{[\Sigma Mn](FeO)}{K'} + \frac{[\Sigma Mn](FeO)(SiO_2)}{K'D'_1} + \frac{[\Sigma Mn]^3(FeO)^3(P_2O_5)}{K'^3D_1}.$$

By substituting in this equation the value of (P_2O_5), as given in the previous equation and a similar one for (SiO_2), another expression is obtained which gives the greatest possible concn. of (ΣMnO) that can be present with the MnO in the slag when equil. prevails. If equil. has not been reached, then Mn must be reduced or oxidized, depending on whether the total Mn-content of the slag is greater or smaller than the right side of the equation By other expressions it is shown that the Mn content of the steel or slag is not definitely known at any time, if the Mn is reduced or oxidized. The evaluation of the equations for dephosphorization and Mn combustion is difficult, because the values of the consts. and their variation with temp. have not yet been detd. The chem. processes taking place in deoxidation are also discussed. J. Balozian

Observations of the height of ozone in the upper atmosphere. F. W. P. Götz and G. M. B. Dobson Lichtklimatisches Observatorium, Arosa. *Proc Roy Soc* (London) **A120**, 251–9(1928); cf. Dobson, Harrison and Lawrence (*C. A.* **21**, 2097).—The *ozone* was determined spectrographically. To find the equiv. vertical distance the first thickness is divided by the secant of the sun's zenith distance. Correction must be made when the sun is low, due to curvature of earth's surface. In practice 5 curves drawn showing calcns. of ozone on assumptions of various thicknesses, 0, 30, 40, 50, 60 km. The one most const. was taken as correct for the day. The effect of refraction is negligible for this work. The evidence showed an increase in the height of ozone between autumn and spring and that an increase in the amt. of ozone assocd. with cyclones must occur in the upper part of ozone layer rather than the lower. The av. height is 30–40 km. above sea level Arthur Fleischer

Colorimetry. H. Eckstein. *Chem.-Ztg.* **52**, 317(1928).—The suggestion is made that the changes in color of many of the comparison solns. used in colorimetric detns. might be avoided either by the use of suitably colored stable dyes or of colored glasses as comparison standards when such materials can be obtained. B. C. A.

Calculation of the rotatory power of quartz. R. de Mallemann. *Compt. rend.* **186**, 1046–8(1928); cf. *C. A.* **21**, 2419.—The exptl. results of Ze (*J. phys. radium* 9, 13–37(1928)) are used to deduce the value of the mol. anisotropy which figures in the author's expression for the rotatory power (*C. A.* **21**, 2419). A value of 30°/mm was obtained for quartz at $\lambda 0.546\mu$ (observed value 25.5°/mm.). The agreement is considered satisfactory in view of the indirect method employed and the low exptl accuracy. It is improved if allowance is made for the slight inclination of the plane of principal mol. axes with respect to the ternary crystal axis, the existence of which is indicated by the work of Ze and of Bragg. B. C. A

Ultra-violet refractometry. L. C. Martin. *Trans. Optical Soc.* (*England*) 29, 1–21(1927–28).—A critical-angle method is described for detg. the *n*s of small quantities of liquid for ultra-violet light. Two quartz hemispheres, between which is a thin film of the liquid, are rotated in a beam of approx. parallel radiation, and the critical angles for various wave lengths are measured by means of a quartz spectrograph. A detailed procedure is described and discussed. B. C. A.

Remark on the communication of G. Landsberg and L. Mandelstam on a new effect in the light dispersion by crystals. H. Kornfeld. Vereinigte Stahlwerke, Dortmund. *Naturwissenschaften* **16**, 653(1928).—The 9.1μ value for the proper vibration of $CaCO_3$ found by L. and M. (*C. A.* **22**, 3837) corresponds to an optically inactive proper vibration of the CO_3 ion (*C. A.* **18**, 3313) found by the author (about 8μ) and confirmed by Schäfer, Bormuth and Matossi (*C. A.* **21**, 360). B. J. C. van der Hoeven

The absorption of the visible and ultra-violet light and the interference of x-rays in tourmaline. Paul Stamm. *Neues Jahrb. Min. Abt. A, Beil.-Bd.* **54**, 293–319 (1926). J. F. Schairer

Reflection in complex systems. G. I. Pokrovskii. *Z. Physik* **47**, 898–903 (1928).—In many cases analyses of substances according to the degree of reflection can be of much practical importance, *e. g.*, in the estn. of iron oxide or carbonaceous substances in the earth and in minerals and in detn. of the compn. of flour or of dyes. Analogous methods may serve in investigations of the surfaces of plants. The connection between compn. of substances and their color, etc., is shown by the method. Quant. analysis of substances by the intensity of reflected light was first carried out by P. Here, the reflection of disperse systems, composed of different kinds of elements, is considered. In the case of pulverulent substances a simple law has been found in good agreement with expt. The connection between compn. of a mixt. and its reflection is established, which is important for the quant. *analysis of pulverulent substances.* The paper is largely mathematical. S. L. B. Etherton

Is the molecule of gaseous hydrogen chloride polar or non-polar? F. I. G. Rawlins. *Z. Physik* **50**, 440–2(1928).—From a consideration of the pure rotation spectrum of HCl, of the constancy of its dielec. const. in a variable magnetic field, and of the lack of variable intensity in the short ultra-red, it is concluded, contrary to Kondratjew's view (*C. A.* **22**, 2874), that gaseous HCl is polar. It is suggested that an exptl. study of the relation of the rotation part C_{rot} of the sp. heat to the equipartition value R at temps. near 12° abs. might answer the question more definitely. R. J. H.

Method for obtaining a stream consisting of a mixture in any desired proportions from two or more receptacles which contain the different liquids. A. Sivolobov. *J. Chem. Ind.* (Russ.) **4**, 543–5; *Chem. Zentr.* **1927**, II, 2210.—The 2 liquids fill the 2 side arms of a U-tube. The height of the liquid columns is so regulated that they flow out in the desired proportions from an orifice at the bottom of 1 side arm. The surface of sepn. of the liquids remains at all times at the level of the orifice. C. C. Davis

Recent advances in science: Meteorology. E. V. Newnham. *Science Progress* **23**, 197–203(1928).—A review of recent work on the O_3 and H_2O content of the atm. Joseph S. Hepburn

Investigation of atmospheric deposits. I. W. Liesegang. *Kl. Mitt. Ver. Wasserversorg. Abwässerbeseitig* **3**, 317–27; *Chem. Zentr.* **1927**, II, 2274.—A detailed critical compilation of all the accessible literature which has appeared up to the present time of the chem. nature of atm. ppts. The values ascertained by previous investigators are contained in numerous tables, together with those of L. C. C. Davis

The Pauli exclusion principle. P. Jordan and E. Wigner. *Z. Physik* **47**, 631–51 (1928).—If a body of gas is considered to be a 3-dimensional wave field with non-commutative multiplication of amplitude, and if the Pauli principle of restricted equivalence is applied, it is possible to develop the theory of the gas without use of the concept of abstract phase space, using only the ordinary three dimensional coördinates. F. R. B.

The distillation of water-soluble organic substances with steam. Artturi I. Virtanen and L. Pulkki. *Ann. acad. sci. Fennicae* **29A**, 28 pp.(1927).—If care is taken in the design of the distn. app. to see that all vapor volatilized passes over into the condenser and collecting flask, the following equation represents the change in compn of the liquid on distn.: $(\log y_1 - \log y_2)/(\log x_1 - \log x_2) = k$, where x and y refer, resp., to the quantities of water and of volatile org. compd. and subscripts 1 and 2 refer, resp., to the quantities at the beginning and end of the distn. By this equation, the purity of a soln. of org. compd. such as a fatty acid can be proved by the constancy of k in successive distn. fractions. The influence of initial concn. and time of distn. on the value of k for dil. solns. of formic, acetic, propionic and butyric acids was studied. Concn affects k only to a slight extent but the time of distn. influences k significantly so that it must be kept within close limits in quant. work. The rate of distn. adopted was 100 cc. of an original vol. of 200 cc. in 60 min. A mixt. of 2 volatile compds., *e. g.*, 2 fatty acids, can be analyzed by detg. the total acidity of the initial soln. and of the distillate when half of the soln. has passed over, provided that k for each of the acids is known. A mixt. of 3 acids can be analyzed by detg. the total acidity of initial soln. and distillates when $^1/_4$ and $^1/_2$ of the sample has passed over. When more than 3 acids are present the exptl. errors become too large. If a compd. has a value for k greater than 5 the exptl. errors are too large. Values for k are given for the following acids: formic 0.398, acetic 0.657, propionic 1.270, butyric 2.02, diethylacetic 4.57, chloroacetic 0.047, phenylacetic 0.070, pyruvic 0.074, α-crotonic 0.760, benzoic 0.270, salicylic 0.688, *o*-toluic 0.508, *m*-toluic 0.420, *p*-toluic 0.378, anisic 0.050, cinnamic 0.102, *o*-aminobenzoic 0.019; *m*- and *p*-aminobenzoic and the 3 nitrobenzoic acids do not distil. Approx. values of k for amines are: ammonia 13, methylamine 11, ethylamine

20, propylamine 30, butylamine 40, diethylamine 43, ethylenediamine 0.02, aniline 5.51, methylaniline 16, benzylamine 3.25, α-naphthylamine 1.05, β-naphthylamine very large. For phenols k is: phenol 1.94, *p*-chlorophenol 1.30, *p*-nitrophenol 0.005, *m*-nitrophenol 1.01, thymol 12; for aldehydes: formic 2.6, acetic 40, benzoic 18, anisic 3.1; for alcs.: methyl 8.9, ethyl 12.9. The volatility of a compd. with steam increases as the hydration in soln. decreases. Neutral salts influence the volatility by altering the hydration, usually decreasing hydration and increasing k. Anions have a greater influence than cations. A given salt has a greater influence on less sol. than on more readily sol. volatile compds. There is a striking parallel between the action of salts on the volatility and on the adsorption of compds. from soln. by charcoal.

Non-equilateral triangular systems of Rutherford-Bohr. U. CRUDELI. *Nuovo cimento* **4**, 85–95(1927).—Largely math. The non-equilateral triangular systems of Rutherford-Bohr are of importance with respect to models of the He atom. Designating the magnitude of the masses relative to the two vertices bearing equal charges as m and the charge on the other vertex as M (the nucleus) and eliminating the Coulombian hypothesis, one has a neutral, non-equilateral, uniformly rotating Rutherford-Bohr triangular system. Two vertices bear equal charges and masses which do not hold, however, for values of the ratio m/M of less than unity. A general treatment of the Rutherford-Bohr triangular systems is also given for equal charges and masses on 2 vertices, where the sides uniting the third vertex with the other two are unequal.

L. T. FAIRHALL

The correspondence relation between the matrices and the Fournier-coefficients in the hydrogen problem. CARL ECKART. *Z. Physik* **48**, 295–301(1928).—The passing over of the matrix elements of a quantum problem to the Fournier coeffs. of the classical motion for infinitely great quantum nos. and vanishing h is investigated in the specific case of the radius vector in the H atom. The matrix is expressed by means of a formula of Epstein as a hypergeometric function, whose limit for $h \longrightarrow 0$ and quantum nos. $\longrightarrow \infty$ is found to pass over into the Fournier expansion for the radius vector undergoing the Kepler motion. A proof is thus furnished of the truth of correspondence principle for this particular problem.

Quantum theory and chemical bond. F. LONDON. *Physik. Z.* **29**, 558–61(1928).—L. reviews the Heisenberg-Schrödinger theory in respect to the bonding of homopolar compds. According to the Pauli principle an atom consists of a no. of equiv. electrons bound in pairs, and a no. of non-equiv. electrons. In the new quantum theory, when 2 such atoms are brought together the non-equiv. electrons are bound and the 2 atoms form a mol. Such electrons as do not belong to equiv. pairs are valence electrons and their no. gives the valence of the atom. The valences thus detd. for the elements agree with those detd. from chem. considerations.
R. L. HERSHEY

The shared-electron chemical linking. L. PAULING. *Proc. Nat. Acad. Sci.* **14**, 359–62(1928).—London's theory of the formation of valency linkings is equiv. in simple cases to G. N. Lewis' theory of the shared electron pair. A number of new results have been obtained in extending London's simple theory, taking into account quant. spectral and thermochem. data. A sensitive test to det. whether a compd. is polar or non-polar is put forward and it is concluded that HF is polar, while HCl, HBr and HI are probably non-polar. If quantization can be changed, as it can in the case of some elements in the first row of the periodic system where the interchange energy resulting from the formation of shared-electron linkings is large enough to bring it about, very stable shared-electron linkings are possible. This explains the stable shared-electron linkings of satd. C compds., and the relatively stable double linkings of carbon. The tetrahedral arrangement of the four linkings of quadrivalent carbon can be shown to be the stable one as a result of the resonance phenomenon.
B. C. A.

Wave mechanics of rotating electrons. I. FRENKEL. Lenigrad. *Z. Physik* **47**, 786–803(1928).—In connection with previous work on the classical, *i. e.*, corpuscular mechanics F. now deduces the corresponding wave mechanics equations of rotating electrons in a relativity invariant form. The equations obtained are analogous to Darwin's equations but have the merit of being invariant.
S. L. B. ETHERTON

Are electrons waves? C. J. DAVISSON. Bell Telephone Lab. *J. Franklin Inst.* **205**, 597–623(1928).—A review of D.'s expts. The question put by the title is answered by asking "Are x-rays waves?" The expts. and their interpretation are discussed in a simple and most readable manner.
W. T. RICHARDS

Waves of an electron. G. P. THOMSON. *Engineering* **126**, 79–80(1928); *Proc. Roy. Inst. Gt. Brit.* **1928**, 9 pp. (reprint).—The evidence for a wave theory of light is interference and diffraction. But light can also impart motion to an electron, depending upon the kind of light and not upon its intensity. This is almost impossible

if light consists of continuous waves but may be expected if light is composed of discrete particles. De Broglie considered light to be corpuscular but accompanied by waves, thus combining the 2 views. In an elec. or magnetic field the electron does not obey the laws of electricity but goes where its wave takes it, *i. e.*, the electron is refracted and can be focused. Expts. are described to test this view and 3 checks for De Broglie's theory support it. The next questions to be solved are (*a*) what are the waves and (*b*) what is the relation between electron waves, waves of light and of x-rays. Theoretically, an exact knowledge of the speed of an electron implies an infinite wave train, but there cannot be an infinite wave train so that speed of the electron can never be exactly known Reasons are given for stating that an electron has no definity velocity. Electron waves and light waves differ, the first are deflected by elec. and magnetic fields; speeds and penetrating powers differ. The waves of an electron may be considered to be waves in an ether modified by tubes of force. Or the waves may be regarded as an expression of the laws of motion, the uniform motion of Newton's first law being replaced by a plane wave and the electron remaining the reality. S L. B ETHERTON

The wave mechanics theory of metallic conduction. I. FRENKEL. *Z. Physik* **47**, 819–34(1928).—The paper is largely mathematical. F gives a derivation of the formula of Pauli and of Fermi for the partition of velocities of electrons at zero abs. He then compares the result with his previous estn. of the energy at zero abs. and interprets values by the wave mechanics theory of the superposition of resonance waves with amplitude 1. A consideration of these "cathode waves" as a consequence of alterations in density due to the heat motion of the metallic atoms leads to an expression for the elec. cond. of metals. S. L B. ETHERTON

Kinetic method in the new statistics and its application in the electron theory of conductivity. L. W. NORDHEIM. *Proc. Roy Soc.* (London) **A119**, 689–98(1928).—The dynamical theory of gases has been worked out in the new statistics, both for the Einstein-Bose and the Fermi-Dirac statistics, and applied to the special case of the electronic cond. of metals. Sommerfeld's mathematical procedure has been justified A J KING

Reflection of electrons by a crystal of nickel. C. J. DAVISSON AND L. H. GERMER *Proc. Nat Acad. Sci* **14**, 317–22(1928) —In continuation of previous work (*C. A* **21**, 1927), an electron beam was directed against a {111} face of a nickel crystal at various angles of incidence, and the intensity of scattering in the incidence plane measured as a function of bombarding potential and direction Whenever the speed of the incident electrons is comprised within any of certain ranges, changing in location as the angle of incidence is varied, a sharply defined beam of scattered electrons issues from the crystal in the direction of regular reflection In each of these ranges there is an optimum speed where the intensity of the reflected beam is a max. The phenomenon is the analog of the regular selective reflection of x-rays, but the Bragg formula does not hold, although there is a simple correlation between the observed positions of the max. and the positions calcd by the Bragg formula B. C. A

Reflection of atoms by a crystal. A. ELLETT AND H. F. OLSON. *Phys. Rev.* (ii) **31**, 643–7(1928).—For Ca and Hg atoms striking a rock-salt surface the incident and reflected beams are equally inclined to the normal. Na is not reflected. H gives irregular results. B C A.

Optical anisotropy of atoms and molecules. I. RAMAKRISHNA RAO. *Indian J. Physics* **2**, 435–65(1928).—Lord Rayleigh and Born have both suggested that the fact that light scattered by gases and vapors is not perfectly polarized may be due to optical anisotropy of the mols., although neither explains how this anisotropy arises. Raman has suggested that it may be due to the mutual influence of the atoms constituting the

mol. R. develops a theory of mol. anisotropy assuming optically isotropic atoms. The distances between the optical centers of atoms in mols. are then computed from scattering data. The results thus obtained differ widely from the values given by x-ray data, which are shown to be the more reliable. It is therefore concluded that the assumption of optical isotropy of atoms and ions is untenable. Further evidence for the anistropy of atoms and ions is then given, based on the scattering of light by Kr, X, He and A. Evidence is also adduced from the behavior of CCl_4, CH_4, HCl, NH_3, and H_2O. A method for computing the anisotropy of atoms and ions is developed based on the following assumptions: (1) The polarization induced in an atom when light is incident upon it is different along its 3 principal axes. (2) Distances between the optical centers of atoms in mols. are given by the x-ray data for the corresponding interatomic distances. (3) The refractivities of H^+, C^{4+}, O^{6+} are negligible in comparison with the refractivities of the other atoms or ions of the rare-gas type. (4) All atoms have one axis of symmetry, the refractivities along the other 2 axes being equal but different from that along this axis. (5) The interatomic distances in a mol. in the solid and gaseous states are the same. The computed results are given for a no. of ions for which scattering data are accurately known. These show many regularities. The atoms of the rare gases are less anisotropic than the corresponding ions, and heavier atoms show less optical asymmetry than lighter ones. The asymmetry increases with increasing opposite charge on the adjacent ion. The theoretical basis for at. anisotropy is discussed and it is suggested that possibly it may be explained on the basis of the spinning electron. W. W. STIFLER

The large area of operation in the reciprocal action of similar kinds of atoms. WILHELM SCHÜTZ *Z. Physik* **48**, 67–72(1928).—Consideration of the development of the problem of the anomalously large area of operation in substances of the second kind between similar kinds of atoms. Methods for the detn. of this area of Hg vapor in a magnetic field are compared with regard to the new experience relating to the structure and Zeeman effect of resonance line 2537. S. L. B. ETHERTON

The constitution of zinc. F. W. ASTON. *Nature* **122**, 345(1928).—Using zinc methyl, mass spectra indicate that Zn consists of the following isotopes: 64, 66, 68, 67, 65, 70 and 69. The order in the list shows the order of the intensities. F. E B.

Cinematographic sketch of electrically exploded wires. HANTARO NAGAOKA AND TETSUGORO FUTAGAMI Inst Phys Chem. Research, Tokyo. *Proc. Imp. Acad.* (*Japan*) **4**, 198–9(1928).—Instead of photographic exploding wires on films rotating in a plane at right angles to the line of sight, as has been done previously, photographs were taken on a film moving around an axis parallel to the wire. Photographs are given of the explosion of Cu and Fe wires, and of Mg ribbon Luminous particles are expelled at right angles to the direction of flow of current, not continuously but in masses C. J. WEST

Electric explosions. HANTARO NAGAOKA AND T. FUTAGAMI. *Sci. Papers Inst. Phys. Chem. Res.* (Tokyo) **8**, 269–88(1928).—Plain photograms and cinematographic records were made of the progress of explosions of Al ribbon, fuse wire, Fe wire, manganin wire, Hg in glass capillary tubes, Cu wire, Mg ribbon, Ag wire, elec. lamp filaments, and threads soaked with KNO_3 and NaCl solns. The app. consisted of an a. c transformer operating at 200 v. and 50 ~ on the primary, and delivering 40 k. v. The secondary current was rectified by a 100 k v Kenetron and charged a large battery of condensers. For the cinematographic study, an inductance was put in the circuit to exam the successive stages of explosion. In order to view the exploding wires from instant to instant, a rotating drum of peripheral speed 100 m./sec. with a frequency of 160 cycles per sec. was used to operate shutters with 100 and 360 holes. This gave shutter speeds of 1/20,000 sec. in one case and 1/70,000 sec. in another. The results are fully illustrated by photographs. In most cases the metal wires gave rise to the ejection of luminous particles normal to the direction of the current. For easily oxidizable metals, oxide clouds were developed. The light-emitting portions are in the middle of the wire, and are undoubtedly multiply ionized atoms A series of explosions was carried out in transformer oil, favoring high c. ds., temp. and pressure. A c. d of 10^6 amp./sq. cm. did not suffice for the transmutation of Ag, Al, Mg, Tl, Pb, Bi, Sn and Cd. The residue collected from a Hg explosion, however, gave 30 Au lines and 12 Tl lines. This does not constitute unequivocal evidence of the *transmutation of Hg* HOWARD R. MOORE

Experiments on the realization of the decomposition of the lead atom. A. SMITS AND W. A. FREDERIKSE. Univ. Amsterdam. *Z. Elektrochem.* **34**, 350–60(1928); cf. *C. A* **21**, 855.—The results of the expts. on the transmutation of Pb nto Hg are described. With a specially constructed quartz-Hg lamp very definite positive results

were obtained. This lamp was broken and it was found quite difficult to reproduce all its properties. After many troubles another lamp was constructed which also gave a positive result but only after a much longer time. In the expectation that another easier and more reproducible method might be found, expts. were made with the sparking and flaming arcs. The results obtained here were negative. The indications are, with radiation, that by exposure of Pb to x-rays for a long time radioactivity can be developed. At present it can only be said that these indications are weak and nothing more. When radioactivity occurs and α-particles are emitted after long-time radiation, it is believed that a Szillard electrometer is more sensitive than the identification of Hg by spectroscopic methods. Using a quartz-Pb lamp a positive result was obtained and this result was reproduced but was not so pronounced as the first. All the materials used, the Pb, Fe, carbon and quartz, were found by analytical chem. methods to be Hg-free, and spectroscopic examn. in a C flaming arc proved Hg absent. It is certain that testing in a quartz-Pb lamp is more sensitive than the carbon flaming arc; however the initial spectrum of the quartz-Pb lamp was also free of Hg lines. The only uncertainty may be that the Fe or C electrodes, although found free from Hg by analytical chem. and spectroscopic methods (flaming arc), may yet contain traces of Hg which after the lamp has been run for a time are taken up by the Pb and so Hg lines are found. In the light of these facts the transmutation of Pb into Hg cannot be considered as proved yet. Further work with radiation is to continue. M. R. FENSKE

The atomic synthesis manifested in connection with atomic disintegration, and the theories of the building up of atoms from hydrogen and helium. WM. D. HARKINS. Univ. of Chicago. *Z. Physik* **50**, 97–122(1928); cf. *C. A.* **17**, 3131, 3449.—Out of a total of 45,000 fog track photographs taken by H. and his coworkers, two cases are found in which an α-particle unites with a N kernel, followed by immediate splitting with loss of a proton. A description is given of the "sieve plate" method of obtaining the special coördinates and angles of intersection of these tracks. The min. energy of the α-particle for obtaining these phenomena seems to be from 2.7 to 3.5 $\times$ 10^6 v. A review follows of the theories of H. on at. structure and the periodic system as confirmed by H.'s more recent work. G. M. EVANS

The generation of heat in potassium salts by the radioactive potassium isotope. JOH. KOENIGSBERGER. Univ. Freiburg *Kali* **22**, 266–7(1928).—Assuming the max. possible heat evolution from the Rb and K radioactive isotopes, it is not sufficient to have a detectable influence on the temp. gradient of the earth or on the temp. in K mines MARIE FARNSWORTH

Separation of isotopes of potassium. G. VON HEVESY AND M. LÖGSTRUP. *Z anorg. allgem. Chem.* **171**, 1–13(1928).—By subjecting K to the process of ideal distn. (cf. *C. A.* **16**, 1180), a residue was obtained having at. wt. 39.109, corresponding with an increase of 4.8% in the proportion of the isotope K^{41}. As the radioactivity increased at the same time by 4.2%, it is concluded that this isotope is probably responsible for the radioactivity of K B C. A.

The actinium problem. G. ELSEN. *Chem. Weekblad* **25**, 517–23(1928).—The theories on formation and decay of Act are reviewed. It is possible that a U isotope of higher at. wt. than U I exists and is the parent of the Act series. At. wt. detn of PrAct is considered most significant for a decision in this matter. B. J. C. v. D. H

Condensation of water vapor on charged atoms of actinium A. MINESABURO AKIYAMA. *Compt. rend.* **187**, 341–2(1928).—Trajectories of α-particles emitted by actinon and Act A have sometimes their origins well sepd., yet close. Two photographic app. at 45° to the axis of the expansion chamber were used. The trajectories were visible under a pressure of 530 mm. Hg. Fifty-seven out of 74 had their origin at the same place. Certain atoms of Act A coming from actinon did not increase in wt. to immobility although produced in an atm. satd. with H_2O. They are attracted to an applied elec. field. L. D. R.

Radium, uranium and vanadium. ANON. *Mineral Ind.* **36**, 522–4(1927).—A statistical review. A. B.

The radium and thorium contents of volcanic rocks from Hegau. HEINRICH LEDERER. *Ber. naturforschend. Ges. Freiburg i. Br.* **27**, No. 2, 20 pp.; *Chem. Zentr.* 1927, II, 2273.—The rocks were first decomposed and the quantity of emanation evolved during a given time was detd. by comparison with a Ra-normal soln. According to these expts. the rocks in Hegau can be divided into 3 groups: (1) phonolites with a Ra content of 8.03 – 4.1 $\times$ 10^{-12} g.; (2) basalts with 2.33 – 1.01 $\times$ 10^{-12} g. and tuff with 1.05 – 0.00 $\times$ 10^{-12} g. of Ra per g. of rock. The Th content amounted to 6.18 $\times$ 10^{-6} g. Th for the first group, 0.57 $\times$ 10^{-6} g. Th for the second and 1.01 $\times$ 10^{-6} g. for the last. The measurements of Kaiserstuhl rocks agreed with those of earlier in-

vestigators except for the phonolites. The tephrites are richer in Ra than the basalts of Hegau. C. C. DAVIS

The radium and thorium contents of the phonolite of Kaiserstuhl. WOLFGANG SEITH. *Ber. naturforschend. Ges. Freiburg i. Br.* 27, No. 2, 4 pp.; *Chem. Zentr.* 1927, II, 2273.—Various phonolites and tephrites from Kaiserstuhl were studied and a Ra content of 4.83×10^{-12} and a Th content of 4.25×10^{-5} g. were found. The values for tephrite amount to 6.62×10^{-12} Ra and 4.33×10^{-5} g. Th, without great variations, as supposed by Lederer. From them may be calcd. a U content of 1.55×10^{-5} and 2.10×10^{-5} g. resp. per g. of rock. The Kaiserstuhl also shows a somewhat higher content in radioactive substances than Hegau. C. C. DAVIS

Radioactive haloes in fluorite from Wölsendorf. A. SCHILLING. *Neues Jahrb. Min. Geol. Abt. A, Beil.-Bd.* 53, 241–65(1926).—The numerous types of haloes in the Wolsendorf fluorite are described and photomicrographs given. The sepn. of colloidal metallic Ca is given as a cause of the color. Precision measurements were made on the range of α-particles from U I and U II. J. F. SCHAIRER

Radioactive waters in Poland. SEWERYN GRABIANKA. *Roczniki Chem.* 8, 183–94 (1928).—The spring Cisowy Dworek at Sromowce (near the Tcheko-slovakian border) had the highest radioactivity of the 9 springs examd.: 9.72 Mach units. A Schmidt electroscope was used. MARY JACOBSEN

Dependence of the speed of separation of radium F on the nature and the state of the precipitating metals. G. TAMMANN AND C. WILSON. Göttingen Univ. *Z. anorg. allgem. Chem.* 173, 137–55(1928).—Since a metal in the hard condition is less noble than in the soft condition it may be expected to ppt. nobler metals with greater velocity than the same metal in the soft state. Should the soln. to be pptd. be concd., then the surface of the pptg. metal is soon covered; hence, to study the subject, dil. solns must be used. With metals less noble than Ra F, soft Cu and Ni ppt. rapidly all Ra F atoms meeting its surface, while soft Ag and Fe only ppt. a portion. Let a be the original amt. of Ra F in the soln., x the amt. pptd. in time t, F the surface of the pptg. metal and v the vol. of the soln. in which the amt. a is available, then $dx/dt = (kF/v)(a - x)$; hence on integration $k = (2.3026v/Ft) \log a/(a - x)$. The Ra F pptd. was measured by a gold leaf electroscope. The error in the detn. of Ra F rapidly increases with the radioactivity of the metal used to ppt. it. When the velocity of pptn. is much greater than the velocity of diffusion, the pptn. const. k should have the same value for different metals. But this was not found to be the case. Hence it was assumed that for elements with smaller k, each collision of a Ra F cation did not mean a deposit. From Nernst's theory $k = D/\delta$, where D is the coeff. of diffusion and δ the thickness of the pptd. layer on the pptg. metal, k is calcd. to be 8×10^{-4}. k for hard Ag is 16.3% greater than for soft Ag. Where the metal used is more noble than Ra F, *e. g.*, Au, Hevesy considers that here the Au ion goes into soln. and Ra F ions transfer their charge. T. and W. suggest that the Ra F is adsorbed in the Au and Euler has shown that Ag ions are adsorbed by Au. In the first case, the amt. of the pptd. Ra F will be proportional to the concn. of the Ra F in the soln. In the second case it will be proportional to a power of the concn. as in other adsorption isotherms The latter was found to be the case. Hard Au, Pd and Pt adsorb Ra F twice as rapidly as in the soft state and the same holds for Cu-Au and Ag-Au alloys. Active Cr ppts. Ra F but when passive it absorbs very little. It alloys with ferromagnetic metals, when they do not become passive, ppt. Ra F. S. L. B. ETHERTON

Fractional crystallization of radioactive substances. III. The distribution of radium between solid crystalline $BaCl_2 2H_2O$ and its saturated aqueous solution at t = 0° and t = 35°. VITALIUS KHLOPIN AND ALEXANDER POLESSITSKII. *Z. anorg. allgem. Chem.* 172, 310–20(1928); cf. *C. A.* 22, 1723.—The extremely small quantities of Ra have no practical influence on the 2 phases so that the present case is not analogous with ternary systems of 2 electrolytes which form mixed crystals and water. Henderson and Kracek (*C. A.* 21, 1590–1) in their fractional pptn. of Ba-Ra chromate concluded that the distribution of Ra is analogous to the distribution of a substance between 2 non-miscible solns. The partition factor $D = kc/d$, where c is the amt. in g. of Ba salt per cc. of the satd. soln. and d = sp. gr. of the solid phase. Detns. of D differ with different investigators, though these deviations were probably due to variations in temp. and acid concn. The distribution of Ra between solid $BaCl_2$ and the neutral satd aq. soln. strictly obeys the Bertholet-Nernst distribution law. The distribution ratio, K, remains strictly const. at const. temp. and const. compn. of the liquid phase as well as under large differences in the relative amts. of both solvents. Greatly increasing the concn. of the Ra salt (2×10^3 times) does not affect K. K depends on temp. and the temp. coeff. for this system, between 0° and 35°, is —0.516 per degree,

and from 35° to 57.5° it is —0.275 per degree. Fractional crystn. of Ra chloride and bromide improves with fall in temp. S. L. B. ETHERTON

Velocities of α-particles from radium C, thorium C and C′. G. H. BRIGGS. *Proc. Roy. Soc.* (London) **A118**, 549–57(1928).—The value of $H\rho = MV/E$ for an α-particle from Ra C has been redetd., the app. for producing the magnetic deflection being modified (cf. *C. A.* **21**, 1590). From the value found, 3.993×10^5 e. m. u., and the theoretical value of E/M, 4814.8, calcd. from recent detns. of the at. wt. of He and the value of the faraday, taking into account the relativity correction for the increase in mass of the α-particle, the initial velocity of α-particles from Ra C is found to be 1.923×10^9 cm./sec. The values found by Rutherford and Robinson were $H\rho = 3.983 \times 10^5$ and $V = 1.922 \times 10^9$ (cf. *C. A.* 9, 21). The initial velocities of α-particles from Th C and C′ are found to be 1.705×10^9 and 2.053×10^9 cm./sec. resp. These results are compared with those deduced from the Geiger relation $V^3 = kR$, and found to be in good agreement. A table is given showing the velocities of α-particles from other radioactive substances, the results being deduced from the author's velocity curve for α-particles from radium C (*loc. cit.*) and from Geiger's determination of the ranges (*C. A.* **16**, 3434). B. C. A.

Ultra-violet spectrum of radon. STEFAN WOLF. *Z. Physik* **48**, 790–4(1928).—The spectrum of Ra emanation, hitherto only known in the visible region, is now photographed with a quartz prism app. and about 100 new lines between 3600 and 2400 A. U. have been measured. A new form of *spectral tube* is given with which without the use of quartz a further step forward in the ultra-violet is possible. S. L. B. E.

The radiation of protactinium. OTTO HAHN AND ARISTID V. GROSSE. Kaiser Wilhelm Inst., Berlin. *Z. Physik* **48**, 1–10(1928).—Protactinium, the element of long life with at. no. 91, emits α-particles and changes to actinium, 89. H. and G. now use a very concd. Pa prepn supposed to be free from other radioactive elements and find another weak radiation which they characterize as β. With a completely enclosed cylindrical β electroscope, absorption curves of these rays have been obtained and compared with corresponding β-rays from radioactinium The time change in the curves was another proof that the β-radiation was not due to any other impurity. The intensity of the β-rays of Pa compared with the α-rays was compared with similar results with other Act products. Along with the β-rays, γ-rays were found also. The thickness for half value of Pa rays is 0.055 mm. and the absorption coeff. in Al is 126 cm. The γ-rays of Pa are more penetrating than β-rays of the active ppt. of actinium. S. L. B. ETHERTON

Vaporization of polonium in vacuum. P. BONÉT-MAURY. *Compt. rend.* **187**, 115–7(1928); cf. *C. A.* **21**, 3011, 3544.—App. previously described was used. The form and position of the cold wall and source have been modified. L. D. R.

Radioactive precipitates on high antennae. F. SCHINDELHAUER. *Physik Z.* **29**, 479–87(1928).—An earthed conductor of capacity C in the earth's elec. field becomes charged with a quantity of electricity Q such that $Q/C + V = 0$, where V is the potential of the region in which the conductor is situated. A current flows through the conductor to earth if the elec. field changes, or if the surface charge on the conductor is lost owing to the presence of ions in the surrounding air. The currents produced in the high antennae at Potsdam Observatory by the second cause were investigated; during the period of observation they had a mean value of 3×10^{-15} amp./sq. cm., a value some ten times greater than those previously reported. It is concluded that the currents are produced principally by deposition of radioactive material on the conductor for the following reasons: (1) Changes in conditions, such as atm. pressure and ground temp., which det the escape of radioactive gases from the ground, produce concomitant changes in the current. (2) The current varies with wind pressure, and the vertical temp. coeff. of the air in the same way as the radioactive content of the air, and diurnal variations in the current are similarly connected with the diurnal variations of the concn. of radioactive gas in the lower atm. W. WEST

Radon pump. L. F. CURTIS. *J. Optical Soc. Am.* **17**, 77–80(1928).—Rubber tubing and stopcocks through which Hg must pass are eliminated. The pump is designed to remove Rn from a soln. of Ra salts. Two Toepler pumps in series are used The Rn is purified in the usual way by sparking, passing through P_2O_5, KOH, CuO bulbs, and freezing down with liquid air and pumping off uncondensed gases. L. D. R.

Ionization curve in pure hydrogen relative to the α-rays of polonium. FREDERIC JOLIOT AND TADASHI ONODA. *J. phys. radium* **9**, 175–9(1928).—17.30 ± 0.03 cm. is the path in H_2. The stopping power is deduced to be in ratio to air 0.223. The range in air is 3.87 ± 0.01 cm. at 15° and 760 mm. Hg. L. D. R.

Number of ions produced by α-rays of radium C′ in air. IRENE CURIE AND FREDERIC JOLIOT. *Compt. rend.* **187,** 43–5(1928); cf. *C. A.* **22,** 3827.—Using satn. currents i_α corresponding to the absorption of α-rays in the Mme. P. Curie app. and current i_γ produced by an ionization chamber receiving γ-rays emitted by the source (Ra B + Ra C), filtered by 15 mm. Pb, currents i_α and i_γ are alternately measured. The chamber for penetrating rays has been carefully standardized. Using 4.774×10^{-10} E. S. U. as elementary charge and 3.7×10^{10} or 3.45×10^{10} as the no. of α-particles emitted by 1 g. of Ra, the no. of ion pairs produced by an α-particle from Ra C′ is found to be 2.2×10^5 or 2.36×10^5. It is concluded that the real form of the Bragg curve relative to the α-rays from Ra C′ should be intermediate between that of Henderson and that of Irene Curie and F. Behounek. L. D. R.

The phenomenon of groupings of atoms for emanation and for mixtures of radioactive elements. C. CHAMIE. *Compt. rend.* **186,** 1838–40(1928).—Cf. *C. A.* **22,** 725. Three methods of making photographs have been used: with Rn included in Hg; directly with Rn from mixts. of radioactive elements; emanations from radioactive elements form groups which give starlike photographs, the rays corresponding to paths of particles from the different elements used. Mixts. give rather heterogeneous groupings but there are similar groupings of the same family. L. D. R.

Spectroscopy of γ-rays by crystalline diffraction. MARCEL FRILLY. *Compt. rend.* **186,** 1614–5(1928); cf. *C. A* **22,** 2876.—In the region of 20 U X four other lines are obtained – 16, 24, 26 and 29.5 U X. 24 and 26 U X are difficult to sep. The results of these expts are in agreement with those of photo-elec. spectra within the limits of the precision of measurements. In 15 hrs. with 500 millicuries a weak impression of lines 16.2 and 35 U X is obtained. The other 3 lines are obtained with an exposure of 3 days. L. D. R.

New diffused radiations. Y. ROCARD. *Compt. rend.* **186,** 1107–9(1928).—The radiations described by C. V. Raman (*Indian J. Physics* **2,** Part III, 1 (1928)) are discussed. These radiations differ in wave length from the incident radiation. They seem to be optical beats due to various frequencies of oscillation of the elec. moment of mols. L. D. R.

The Raman effect. PETER PRINGSHEIM. *Naturwissenschaften* **16,** 597–606 (1928).—The Raman radiation effect (*C. A.* **22,** 1079, 1907) consisting of frequency changes in visible light scattered by a liquid with wave lengths varying with and related to the incident light (differing from fluorescence) is discussed at length. The phenomenon is related to the Tyndall effect: the intensity of the scattered light increases close to the crit. condition of the liquid. The explanation of the Raman effect as an analogon of the Compton effect for x-rays is accepted. The energy yielded by the quanta of the incident rays to liquid mols. serves for nuclear vibrations (not for kinetic propulsion); the scattered ray is of correspondingly lower frequency. Evidence for this theory is contained in the independence of the shift on the condition (solid or liquid) of the scattering body and in the appearance of equal shifts, attributed to excitation of certain molecule groups (C-H, C-C) in various org. liquids (cf. Rocard, preceding abstract, Cabannes and Daure, *C. A.* **22,** 3096; Raman and Krishnam, *Indian J. Phys.* **2,** 399(1928)). The nuclear vibrations here assumed are identical with those found from ultra-red research. The corresponding anti-Stokes lines (of equally higher frequency) have also been found in the Raman effect. Difficulties are experienced in the explanation of the latter on the basis of Schrödinger's wave mechanics.
B. J. C. VAN DER HOEVEN

The theory of the Raman effect. M. BORN. *Naturwissenschaften* **16,** 673(1928).—Several of the peculiarities of the Raman effect (relative line intensities specially) are in complete accord with the statistical interpretation of quantum mechanics even if Schrödinger's equation does not offer an explanation. B. J. C. VAN DER HOEVEN

Penetrating radiation. J. CLAY. *Proc. Acad. Sci. Amsterdam* **30,** 1115–27(1927).—Measurements of the penetrating or ultra-γ-radiation have been made at Bandoeng, Java, from February to July. There appears to be a daily variation in intensity with a min. at about 8 A. M., which is always maintained, although the av. value for the day may vary with the season. Absorption expts. indicate that there are at least 2 different kinds of rays, with possible mass absorption coeffs. of 17×10^{-3} cm.$^{-1}$ and 4×10^{-3} cm.$^{-1}$, which are greater than those found by Millikan and Cameron (*C. A.* **21,** 700). The wave lengths calcd. from these are 3×10^{-11} and 0.8×10^{-11} cm., resp. The intensity of the radiation appears to decrease with increasing altitude at first and then to increase. A penetrating radiation was also observed in a rock-salt mine in Stassfurt. B. C. A.

Astrophysical aspects of the general field of penetrating radiation. B. P. GERASI-

MOVIČ. *Proc. Am. Acad. Arts Sci.* **62,** 173–85(1928).—The flux of penetrating energy outside our atm. is calcd. from the results of Millikan and Cameron, to be 10^{-6} ergs per second per sq. cm. The energy of the free electrons produced in a rarefied gaseous layer in this radiation field is high, but the percentage of atoms ionized is, for Eddington's interstellar gas (H), only of the order of 10^{-8}. The local fields within nebulas, unless they are absurdly strong, cannot give effects of the order of those produced by stimulating stellar radiation. W. T. RICHARDS

Rendering h rays visible. HANS PETTERSSON. *Z. Physik* **48,** 795–8(1928).—Two simple methods are described: (*a*) Wilson's method, (*b*) scintillation method, to render visible natural *h* rays from α irradiated paraffin. S. L. B. ETHERTON

Dependence of the photographic action of β-rays on their velocity. C. D. ELLIS AND G. H. ASTON. Trinity College, Cambridge. *Proc. Roy. Soc.* (London) **A119,** 645–50(1928).—Electrons with energies above 200,000 v. were used (β-particles from Ra, B and C). Relative photographic activities were plotted against velocity. Comparison of the exptl. curve with the theoretical one for the ionization shows that the exptl. activity changes at first less rapidly and finally more rapidly than the theoretical. GREGG M. EVANS

Experiments on the diffraction of cathode rays. II. G. P. THOMSON. Corpus Christi College, Cambridge. *Proc. Roy. Soc.* (London) **A119,** 651–62(1928); cf. *C. A.* **22,** 1723.—The deBroglie wave theory was found to agree with expt. in diffraction patterns from electrons passing through thin Pt, and in calcn. of grating consts. for Al, Au and Pt. The velocity of the diffracted electrons differs by less than 1% from that of the main beam. Electrons must be accompanied by a train of not less than 50 waves. GREGG M. EVANS

Diffraction of cathode rays by thin celluloid films. ALEXANDER REID. Univ. of Aberdeen. *Proc. Roy. Soc.* (London) **A119,** 663–7(1928).—The deBroglie wave theory has been tested by obtaining diffraction patterns of the Hull-Debye-Scherrer type from electrons passing through thin celluloid films. Voltage measurements by electrostatic deflection agreed within 1% with spark gap measurements by Thomson (cf. preceding abstr.) The spacing of the planes giving the deflection is calcd. as 4.46 A. U. G. M. EVANS

Diffraction of cathode rays by thin films of copper, silver and tin. R. IRONSIDE. Aberdeen Univ. *Proc. Roy. Soc.* (London) **A119,** 668–73(1928); cf. preceding abstr.—A corroboration of previous work. Agreement with x-ray data is within 1%. G. M. EVANS

The scattering of cathode rays. B. F. J. SCHONLAND. Univ. of Cape Town. *Proc. Roy. Soc.* (London **A119,** 673–80(1928); cf. *C. A.* **20,** 541.—Previous expts. have been found inadequate for a test of relativity correction for the orbits of deflected β-particles. A mathematical treatment of the correction is given, leading to an estimate of the amount of scattering to be expected. This is in fair agreement with expt G. M. EVANS

Back diffusion and secondary radiation of moderately soft cathode rays on metals. K. H. STEHBERGER. Heidelberg Radiol. Inst. *Ann. Physik* **86,** 825–63(1928). —An app. is described in which the distribution of velocities of the secondary electrons from an x-ray target can be quantitatively studied. The true secondary rays have velocities of 0 to 36 v. independent of type of target and of velocity of exciting electrons. The ratio of the true secondary emission to the electrons due to back diffusion shows that the true secondary emission probably comes from electrons diffusing backwards. F. R. B.

Use of the negative charge of cathode rays as writing medium in cathode oscillographs. P. SELÉNYI. *Z. Physik* **47,** 895–7(1928).—Up to the present, phosphorescence and the cathode oscillograph have been used for recording purposes. S. uses another property with which it is simple to work. Cathode rays are directed upon an isolated plate set upon the internal glass wall of the tube. Curves are obtained because of the elec. charges. These are rendered visible by dusting the outer surface with S and red lead. Any electroscopic dust will serve and the Lichtenburg figures will be disclosed. It is expected that this process may afford a writing speed of 30 km./sec. S. L. B. ETHERTON

Connection between positive rays and the abrupt change of potential at the cathode for the thermal emission from an oxide cathode. Method of obtaining the energy of emission. GERHARD SCHMERWITZ. *Z. Physik* **48,** 259–75(1928).—Exptl. details are given for the detn. of the pos.-ray current, the anode current, and the abrupt change of potential at the cathode for a tube with a cathode coated with CaO. The electron stream showed no relationship with the change of potential at the cathode; the pos.-

ray current showed a linear relationship with it for high values, but at about 2.4 volts there was an abrupt change in the curve. Below this voltage there was practically no pos.-ray current. In high vacua the same result was obtained, the value being independent of the temp., and thus of the no. of electrons emitted. It is shown that this critical voltage is the equiv. of the energy of emission of the electrons from the CaO. Similar results were obtained with BaO and SrO, and these agree with the values obtained by Spanner. B. C. A.

Energy of radiation excited by electronic bombardment. PIERRE BRICOUT. *J. phys. radium* [vi], **9**, 88–119(1928); cf. *C. A.* **22**, 726.—An app. is described for the detn. of the relation between the energy of the electrons emitted from a hot filament and the intensity of the radiation excited by them, and a method of measuring the abs. value of the energy emitted is developed. A theoretical explanation of the results is discussed, and a calcn. made of the probability of the emission of a quantum of energy due to a collision between an electron and a neutral atom. B. C. A.

Spectral study of the luminescence of water and carbon disulfide under gamma radiation. L. MALLET. *Compt. rend.* **187**, 222–3(1928).—A special spectrograph, designed by Ch. Fabry, was used for these weak radiations. Two glass tubes, each contg. 250 mg. of Ra as $RaSO_4$, were used as the source. Time of exposure was from 2 to 4 days. The visible region and the beginning of the violet were studied. About 3700 was the limit of the instrument. L. D. R.

Optical experiments with electrons. I. L. H. GERMER. Bell Tel. Lab., N. Y. *J. Chem. Education* **5**, 1041–5(1928).—The wave nature of moving electrons is established. Reflection, refraction, and diffraction have been observed. A stream of electrons directed against a Ni crystal is reflected with angle of reflection equal to angle of incidence. Electrons and x-rays are reflected from a crystal but not from a polycrystalline surface. The electron is also selective in speed of bombardment. "Electrons are diffracted by a Ni crystal as if they were waves having a wave-length given by the quotient of Planck's const. and the electron momentum, *mv*." L. D. R.

Tracks and radiation of electrons emitted by hydrogen. T. ENGSET. *Ann. Physik* **84**, 880–90(1928).—Mathematical. B. C. A.

Magnitude of motion of conducting electrons. II. A. E. MALINOVSKII. *Z. Physik* **47**, 859–85; cf. *C. A.* **21**, 2221.—Faraday considered the elec. current as a kinetic process. Modern electrodynamics assumes moving electrons within the conductor. Tolman and his co-workers are considered to have given a direct proof of this. M. uses an elec. current for elucidation of the magnitude of motion and develops mathematical expressions for the phenomena involved. His app. consists of a ring, half of Cu and half of Bi. This is placed in a highly evacuated space and suspended from a thin filament. A thermocurrent is produced by heating the soldered places with an arc lamp. The rotation of the ring was optically measured as usual. The negative result obtained is discussed theoretically. Conclusion: Self-induction does not affect the electromagnetic magnitude of motion of conducting electrons. S. L. B. E.

Superconductivity according to Schrödinger's wave equation and Fermi's statistics. ERICH KRETZSCHMANN. *Ann. Physik* **86**, 914–28(1928).—In a microscopic isotropic homogeneous metallic conductor in which the elementary charges are acted on by coulomb forces, there is, according to the Schrödinger wave equation, no elec. resistance provided the distribution of energy and momentum is in accordance with the Fermi statistics. F. R. B.

Electromechanical phenomena and free electrons in metals. ALBERT PERRIER. *Bull. soc. vaud.* **55**, 309–13(1926); *Physik. Ber.* **7**, 246(1926).—P. considers the mech. effects occurring parallel to the current direction, and the no. of free electrons in metals. The whole discussion is based only on the classical theory of free electrons. P. calcs. the force exerted on the metal ions by a modification of the elec. field, and shows that this effect may be detected by resonance and used to det. *e/m*. He will try to calc. the no. of free electrons per cc. by means of the present considerations and the use of high frequency oscillations. A L. HENNE

Process of obtaining the maximum of ultra-violet rays with short waves. N. IAROTZKY. *Compt. rend.* **187**, 459–71(1928).—A new type of quartz-Hg lamp is described, using 80,000 v. and giving radiations as low as 253$\mu\mu$. Irritant action on the skin is produced by rays of 300 to 230$\mu\mu$ whereas rays of 260 to 230$\mu\mu$ have the greater bactericidal action. The lamp does not give heat radiations; no heat filters are required, and the patient can be treated nearer the source. E. G. VANDEN BOSCHE

Ultra-violet radiation of a few organic phosphorus compounds following their irradiation. C. SERONO AND A. CRUTO. *Rass. clin. terap. sci. affini* **27**, 167–71(1928).—Irradiated ergosterol slightly darkens the photographic plate. This property is in-

herent in the yellow waxy surface layer which could be sepd. from the inactive remainder and which contains P. A mixt. of cholesterol and *lecithin* from egg yolk had a distinct effect on the photographic plate after irradiation. *Lecithin*, pure *cerebrin* and *chlorophyll* have a pronounced photoactivity after irradiation by a Hg lamp through a Wood screen (360–350$\mu\mu$), while cholesterol, oxyhemoglobin and fresh blood are inactive. The irradiated inactive substances show a vivid greenish violet fluorescence while the active substances have none. The phenomenon is apparently an *ultra-violet fluorescence*, the λ of which is in the vicinity of the exciting one. The facts that a photochem. effect is obtained on a distant photographic plate, that the pictures are neatly bordered when a perforated Pb screen is used and that the activity is preserved for 20 days are sufficient evidence against the assumption of an ozonide. The activatable phosphatides have apparently the function of storing ultra-violet radiation in the living organisms, and of activating metabolism. The fact that lecithin is always assocd. with cholesterol suggests that the latter had a retarding and protective effect. Through its permeability to water in which it is insol it protects the cells without impairing the osmotic or metabolic processes. The catalytic effect of injected lecithin on metabolism finds an explanation in the stored radiation. MARY JACOBSEN

The effect of ultra-violet light on the dielectric properties of crystals. ALBERT A. AARDAL. Ia. State Col., Ames. *Proc. Iowa Acad. Sci.* **34,** 276(1927).—Measurements have been made on the dielec properties of some of the natural crystals, and it has been shown that the values of the consts. are changed upon exposure to ultra-violet light. The most important of these properties are dielec. const., phase angle, and resistance, all of which show this variation when exposed to the short wave lengths. W. G. GAESSLER

Theory of absorption and dispersion in x-ray spectra. R. DE L. KRONIG AND H. A. KRAMERS. *Z. Physik* **48,** 174–9(1928).—An explanation is put forward for the fact that the effective no. of oscillators that must be assocd. with continuous absorption bands in the case of x-rays in order to give the observed dispersion and absorption is different from the no. of electrons in the shell assocd. with the particular absorption band concerned. In particular, the case of the K-band is considered, and it is shown why the effective no. of oscillators is less than 2. B. C. A.

Röntgen ray energy measurements with the selenium intensimeter. W. SCHMITZ *Fortschr. Geb. Röntgenstr.* **35,** 684–97; *Physik Ber.* **8,** 629(1927).—For different Röntgen rays homogenized by filtration, whose abs. energy is detd simultaneously colometrically, the action on a Se cell is systematically investigated for the range from 0.2 to 1.5 A. U. A max. of sensitivity was observed at 0.2 A. U. The Fürstenau cell maintained excellent constancy for long periods. G. L. CLARK

Spectrography with a line grating in the region of soft x-rays. Emission and absorption spectra in the intermediate range. JEAN THIBAUD. *Bull. soc. encour. ind. nat.* **1928,** 481–2; cf. *C. A.* **21,** 1593, 3158. G. L. CLARK

Is crystal reflection of x-rays entirely a classical phenomenon? I. WALLER AND R. W. JAMES. *Nature* **122,** 132–3(1928).—A discussion of the formula of Jauncey and Claus (*C. A.* **22,** 3580) concerning scattering of x-rays, and a method of checking this formula G. R. YOHE

Total reflection. A. ROSTAGNI. *Nuovo cimento* **4,** 218–28(1927).—A pencil of rays from a voltaic arc light adjusted to secure approx parallelism of the rays through a 3-mm. aperture was passed through a glass prism into a layer of CS_2 and impinged at an angle of 60° on the sepg. surface from a thin superposed fluorescent layer of a dil basic soln. The radiation of the region of approx. 390$\mu\mu$ predominates with respect to the various media traversed, *i. e.*, Wood's screen, $CuSO_4$ soln., ordinary glass and CS_2. The purity of the CS_2 and of the sepg. surface was assured so that the possibility of diffraction from particles in suspension was avoided. To det. in order of magnitude the amt. of energy passing into a rarer medium, a layer of fluorescent soln. was produced by an app. for demonstrating Newton's rings and exposed to the luminous pencil The intensity of the fluorescence differs in the various regions and increases with the thickness. Calcd. values agree with observed values. L. T. FAIRHALL

Reflection of hydrogen atoms from crystals. THOMAS H. JOHNSON. *J. Franklin Inst.* **206,** 301–15(1928); cf. *C. A.* **21,** 3543.—Full details are given of an app. for studying the reflection of a ribbon-like beam of at. H from the heated surface of a crystal. The reflected atoms are recorded on a plate coated with MoO_3 which is reduced to metallic Mo by the at. H. Calcite, sylvite, rock salt and quartz all give diffuse reflection if the temp. is high enough. The intensity of this diffuse reflection depends in marked degree upon the temp. of the crystal. Sylvite must be at a much higher temp. than rock salt to give the same intensity of diffuse reflection, while calcite and quartz must

be at temps. between these two. It is suggested that this type of reflection may be explained as an adsorption and reëvapn. of the H atoms at the surface. A cleavage surface of rock salt also gave evidence of specular reflection. An attempt to explain this on the old mechanics of forces between atom and crystal shows these ideas to be inadequate and a discussion is given which is based on wave mechanics. The paper is in the nature of a preliminary report. W. W. STIFLER

Molecular collisions of the second order (excitation of Lyman bands and the non-transformation of the symmetric and asymmetric series of the hydrogen molecule). H. BEUTLER. Kaiser Wilhelm Institut physik. Chem. und Elektrochem. *Z. Physik* **50,** 581-99(1928).—Traces of H_2 in 2-3 mm. argon are subjected to strong discharge to det. the mechanism of excitation of Lyman bands. According to wave mechanics one must assume 2 varieties of H_2 mols. which are, resp., sym. and asym. in the nuclear functions and are not mutually transformable. The selective excitation of the Lyman bands in A-H_2 mixts. can be explained on the principle of resonance in collisions of the 2nd order only by assuming this non-transformation. A. P. SACHS

K-electron ionization by direct impact of cathode rays. D. L. WEBSTER. *Proc. Nat. Acad. Sci.* **14,** 339-44(1928).—The assumptions underlying the theory of indirect K-ionization used in previous work (*Ibid* 330) and here, are first tested by finding the ratio of the indirect K α-line rays of Ag to its continuous spectrum rays of the same wave length. This should be independent of all questions of resolving power, sensitivity function, etc The results obtained are of the right order, although not strictly accurate. The probability of direct K-ionization by a cathode ray in Ag is found to be 0.9 times the probability of an equiv. quantum emission in the continuous spectrum; the ratio is practically const. with change of voltage, and therefore must hold, not only for ordinary thick targets, but for infinitely thin targets also. The absolute probability of direct K-ionization is also estd. with large limits of error, and found to agree with the Thomas theory. It seems probable that the process of direct ionization is not usually an internal photoelec. effect, but rather a process of repulsion between electrons obeying laws much like the inverse-square law. B. C. A.

Potential of ionization of a molecule of water. R. GRINFELD. *Univ. Nac. La Plata, Estudio Ciencias,* No. **82,** 283-93(1928); *Science Abstracts* **31A,** 398.—The method here adopted is that of Lenard (collisions with electrons). A crit. potential of 18.0 v. is obtained. In a discussion of the various possible cases it is found that this value should correspond with the energy necessary to detach the electron from the mol. structure. H. G.

Experiments with modified mucronate electrodes. CARL BARUS. Brown Univ. *Proc. Nat. Acad. Sci.* **14,** 188-91(1928).—The production of ionic currents is investigated by measuring with a form of interferometer the pressure of the elec. wind from a metal point placed within a field of 25 kv. cm. maintained between 2 plate electrodes; curves are given showing the relation between the strength of the wind and the "distance of extrusion," y, of the point into the field. For the cathode point, the wind begins at a y value of 0.06 cm indicating that a p. d. of 1.5 kv. is required to produce a steady emission of neg. charges, resulting in a uniform convection current with a wind pressure which may reach 0.4 mm. Hg. For the anode, the p. d. required to bring about the steady emission of ions is similarly found to be 6 kv. W. WEST

Anode and cathode sparks differentiated by the mucronate ,electrode. CARL BARUS. Brown Univ. *Proc. Nat. Acad. Sci.* **14,** 248-51(1928); cf. preceding abstr.—Further descriptions of sparks produced by the electrode arrangement described above. W. WEST

Polarization of ions in crystal lattices. A. E. VAN ARKEL. Philips' Gloeilampenfabrieken, Einhoven, Holland. *Z. Physik* **50,** 648-56(1928).—Ions are assumed equally polarizable in all directions and the energy of polarization (A) in crystals is calcd. In binary compds. A is least in the CsCl lattice type and increases with increasing coördination no. The experimentally detd. increase of A for the NaCl lattice type and still greater increase for zinc-blende type becomes understandable. Among the alkali halides the CsCl lattice type is found only for compds. with low A, but KF with low A shows the NaCl lattice. If the NaCl lattice structure of CsF is explained by polarization, inadmissably small values of A must be assumed. Where r = the radius of the spherically symmetrical polarizable region surrounding the nucleus and a = the uniform distance of polarizing charges surrounding the ionic nucleus, then $\beta = r/a$, and β is probably always < 0.7. For these values of β, A is shown to have the following order of values CsCl < NaCl < zinc blende. A. P. SACHS

Ionization in nebular matter. B. P. GERASIMOVIČ. *Proc. Am. Acad. Arts Sci.* **62,** 155-71(1928).—The ionization of a planetary nebula stimulated by the radiation

of a very hot star has been investigated assuming that (1) the nebular layer is composed of atoms having only one stationary state and (2) that this is steady and "tangent" to the series of dynamical states The electron temp. thus calcd. depends only on the optical thickness of the gaseous layer and the effective temp. of the stimulating star, and is independent of the diln. of radiation. The derived temps. are between 25,000° and 2000° for different optical thicknesses. A complete ionization formula has been deduced which shows the ionization of normal and metastable H and He nebulae to be very high. The nebular absorption coeff. as a function of d. is discussed in the light of Kramer's theory. W. T. RICHARDS

Ionization on thermal decomposition of ozone. R. RUYSSEN. Univ. Brussel. *Natuurw. Tijdschrift* **10,** 101–16(1928).—A stream of ozonized O_2 from a gasometer was passed through an ionization chamber with electrodes heated to 230° to 240° (sufficient for complete decompn.); the current set up was measured and the no. of mols. passing. The O_3 concn. of the gas entering the ionization chamber was detd. by KI titration, the gas vol. measured in a Juliard anemometer (*C. A.* **22,** 1914). The ionization chamber was a Pyrex glass cylinder with cylindrical electrode at the wall and axial rod, 5 mm. apart, 15 cm. long; it was heated in an elec. furnace. Quartz appeared to give insufficient insulation at high temp. The ionization current was measured by quadrant electrometer (Lindeman) the needle being connected to the inner electrode (outer electrode to a storage battery) and to one side of a standard condenser, which was being charged so as to give a zero reading on the electrometer (quadrants at +41 and —52.5 v.) From time, final potential and capacity of the condenser the current was $i = cV/t$ The accuracy was 10^{-16} amp , total capacity 9.4×10^{-11} farad. For pure O_2 the displacement of the needle was negligible; for ozone very considerable for either positive or negative field in the ionization chamber. The data gathered are for fields of ± 845 to 905 v., ozone content 0.8 to 9.9% by vol., *i. e.*, 0.7 to 8×10^{17} mols. decomposed per sec The flow rate was varied. Increasing rate of flow from a min. up does not influence the ionization (at very low rates some O_3 decomposes at entrance). For m/n, the no O_3 mols. decomposed per sec. per electron charges collected, were found values between 0.8 and 1.3×10^{10} (10^{-11} to 10^{-12} amp); *i e.*, the ionization current was proportional to the no. mols. decomposed The m/n value is independent of field direction; therefore as many + as − ions of about equal mobility are liberated. The ionization rises rapidly and linearly with increasing field At the highest field values (3000 v) signs of satn. begin to appear. For the mechanism of the $2O_3 = 3O_2$ reaction it is concluded that two stages exist: (1) ionization into + and − oxygen ions, a time reaction ($2O_3 = 2O_2 + O^{--} + O^{++}$), (2) recombination to neutral oxygen mols., instantaneous (high m/n value and difficulty of satn.) ($O^{--} + O^{++} = O_2$) B. J. C. VAN DER HOEVEN

Effects produced by positive-ion bombardment of solids: metallic ions. M. L. OLIPHANT. Trinity College. *Proc Cambridge Phil. Soc.* **24,** 451–69(1928).—An unsuccessful attempt has been made to show the nature of energy exchange, but several important anomalies have been revealed. The Kunsman source of positive ions has been used. A W filament such as contained in a Coolidge x-ray tube and coated with the mixt. of oxides is used to supply the ions. A focusing hood made a few volts positive in respect to the filament surrounds the filament. A two-stage diffusion pump produced a vacuum of probably 10^{-8} mm. Expts. support the photoelec. theory of the production of electrons by neutralization of positive ions at the cathode. L. D. R

Electrons and positive ions in pure argon. MARIO A. DA SILVA. *Compt. rend* **187,** 32–5(1928).—Previously results were obtained at 758 mm. and continuous voltage It was decided to learn if all the negative ions were electrons. New curves with alternating voltage, sinusoidal of 42 periods, were plotted. All the negative ions are electrons. L. D. R

Anomalous dispersion of excited gases. I. The proof of the quantum theory dispersion formula. RUDOLF LADENBURG. Kaiser Wilhelm Inst., Berlin. *Z. Physik* **48,** 15–25(1928).—Mainly mathematical. The relation between f and A in the D lines of Na is verified exactly. On the basis of the dispersion formula that is developed, L. dets. the transformation probability and density of excited atoms by measurements of anomalous dispersion. Under these conditions the influence of negative dispersion can be demonstrated. **II. Anomalous dispersion in excited neon.** HANS KOPFERMANN AND RUDOLF LADENBURG. *Z. Physik* **48,** 26–50(1928).—The method used for the investigation of the Balmer lines of electrically excited H, *i. e.*, the method of horizontal interference stria, was used in this work. The influence of current and pressure on anomalous dispersion is shown and is theoretically discussed. About 20 $S_5 = P_k^-$, $S_4^- r_k^-$, $S_3^- p_k$, $S_2^- p_k^-$ lines in the red-yellow were used. S. L. B. ETHERTON

Anomalous dispersion in thallium vapor. V. K. PROKOVIEV AND V. N. SOLOVIEV. *Z. Physik* **48**, 276–85(1928).—The anomalous dispersion of Tl vapor was investigated in the neighborhood of the lines 3776 and 5353, at different temps. from 892° to 1107°. It is found that the ratio of the no. of dispersion centers for these lines varies with the temp. according to the Boltzmann law. From this it is shown that the probabilities of the spontaneous transitions $2s \longrightarrow 2p_1$ and $2s \longrightarrow 2p_2$ (Paschen-Götze notation) are equal. B. C. A.

The smallest electrical carriers in gases. HEINRICH SCHILLING. Univ. Heidelberg. *Ann. Physik* **86**, 447–8(1928); cf. *C. A.* **21**, 3155.—A note supporting S.'s conclusions on the mobilities of positive and negative ions, in spite of the criticisms of Loeb (*C. A.* **22**, 910). H. R. MOORE

A new counting method for corpuscular radiation depending on amplification of true electronic current. EDOUARD RAMELET. *Ann. Physik* **86**, No. 14, 871–913 (1928).—The method of Greinacher (*C. A.* 21, 3544) has been improved by use of resistance coupling and adapted to quant. study. Amplifications of 1.6×10^9 have been obtained. α-particles give varying impulse which is due to decrease of the ionization of the gas through which they pass. The shape of the impulse wave was studied with the oscillograph and the impulse shown to be inhomogeneous in all gases except H_2, which could not be studied on account of the rapid recovery. The impulse depends on the mass of the ionized gas, and is exceptionally great in case of mixed gases. Monatomic gases were not studied. F. R. B.

Chamber for the study of ions and electrons in gases. LEONARD B. LOEB AND A. M. CRAVATH *J. Optical Soc. Am.* **16**, 191–6(1928).—A detailed description is given of a metal ionization chamber suitable for use in research on the mobilities and saturation currents of ions and electrons in gases. The app. has been employed successfully with H_2S. B. C. A.

Accurate measurement of the number of ions produced by a single α-particle, and proof of the existence of new activities. HANS ZIEGERT. *Z. Physik* **46**, 668–715 (1928); *Science Abstracts* **31A**, 381–2.—The app. used comprised a Hoffmann-Duant electrometer recording photographically on a revolving drum, a hollow spherical ionization chamber contained in a Cu bell jar over a massive brass plate, and an elec. arrangement by means of which the electrometer deflections due to β-rays and γ-rays could be balanced. Each α-particle produced a deflection, which appeared on the record as a sudden break in the line traced on the photographic film, the length of the line measuring the alteration in charge of the electrometer and so the no. of ions produced. This length varied, since the velocities of the α-particles are different for different radioactive substances, and also because some of the α-particles hit the walls of the chamber before their energy was exhausted. The lengths of these lines were measured on a measuring machine, which is described, and were dealt with statistically in such a way that it became possible to sep. the effects due to different radioactive components in a mixt. Joffé's satn. theory being taken into account, the following values were obtained for k, the no. of ions produced by each α-particle in air at 0° and 760 mm.: U I, 1.16×10^5, U II, 1.29×10^5; Ra, 1.36×10^5. The no. of α-particles per g. of Ra per second is $Z = 3.71 \times 10^{10}$. Metals for which radioactivity has not been observed were tested. No characteristic activity was found for Cu or Zn, but the metals Al and old Pb were shown to contain an amt. of Ra of the order of magnitude 10^{-14} g. per g. of metal. Residues and ppts. from solns. of Zn showed certainly the existence of new activities, the nos. of ions produced by each ray being 0.42×10^5, 0.69×10^5 and 1.01×10^5. H. G.

Individual scattering from hydrogen nuclei in solid bodies. CHR. GERTHSEN. *Ann. Physik* **86**, 1025–36(1928).—An adaptation of the Geiger ion-counter to the detection of individual canal-ray particles is described. Both the dependence upon the angle and the no. of atoms scattered are in agreement with the Rutherford equation for scattering. W. W. STIFLER

The explanation of dust electricity. H. ISRAEL. Landwirtschaftliche Hochschule, Hohenheim, Stuttgart. *Z. tech. Physik* **9**, 289–93(1928).—The theory of Böning (*C. A.* 22, 540) is discussed. His mechanical explanation of the double origin of the charges (collision and tearing off effect) by inertia of the electrons attached to particles different in size was generally confirmed by expts. consisting of blowing dust off plates. Only in those cases where a rough surface of the plate from which the dust is blown tends to give a collision effect additional to the tearing off effect (sulfur) the sign of the charge was the reverse (dust positive) of the expected one. In 71 out of 98 expts. with different material of plate and dust the dust was found negative; apparently even then the mechanical effect outweighs any other source of elec. charge. For a few substances (minium and chalk) the discrepancies are rather regular. B. J. C. VAN DER HOEVEN

Condensation phenomena at different temperatures. C. F. POWELL. *Proc. Roy. Soc.* (London) **A119,** 553–77(1928).—An app is described, somewhat resembling the C. T. R. Wilson "cloud chamber," whereby the supersatn. required to produce condensation on ions and assocd. mols. in dust-free air may be studied, and the necessary data for detg. the expansion ratio are discussed. A temp. range from —25° to +50° has been investigated. Air is important in this process both because it dets. the amt. of H_2O vapor condensed per unit vol. for a given degree of supersatn., and because it prevents evapn. of water from the walls of the expansion chamber. By extrapolation the supersatn. necessary to produce cloudy condensation at temps. up to the crit. point has been estd., and the state of steam at the cloud limit at different temps. has been calcd. The bearing of these results on the *thermodynamic theory of the steam turbine* is discussed. "Atmospheric temp." is shown to be the best for the investigation of atomic phenomena in a "cloud chamber" W. T. RICHARDS

Disintegration of the cathode. IV. The influence of the composition and the physical condition of the cathode on the sputtering process. E. BLECHSCHMIDT AND A. V. HIPPEL. *Ann. Physik* **86,** 1006–24(1928); cf. *C. A.* **21,** 2425.—An extension of the previously developed theory of the disintegration of the cathode based on the localized evapn. of the metal. The modified expression for the disintegration effect is $I = B\cdot\frac{i}{(1 + C_e)}\cdot(1 - r(\bar{T}))\cdot U_1\cdot\frac{3nk}{\chi b}\cdot e^{-\frac{q_a}{k\cdot T}\;\frac{w_1(\bar{T})}{kT}}$ where I is the intensity of disintegration, B the proportionality factor, i the current density, C_e the no. of electrons freed by each ion impact, r the no. of ions reflected, U_1 the energy supplied, n the no. of atoms, $3k$ the heat capacity of an atom, χ the heat cond., b the mean distance between atoms, v_m the sp. vibration of the atoms, e the base of the natural log., q the at. heat of sublimation and w the escaping energy. The disintegration of metals (Ag, Zn, Cd, Sb, Bi, Pb, Mg, Al, Cu) was studied in a mixt. of He and Ne. All metals with a clean surface gave results corresponding with the proposed formula. J. S. REICHERT

Secondary cathodic radiation in Röntgen tubes containing gas and in tubes free of gas. B. WALTER. *Fortschr. Geb. Rontgenstr.* **34,** 129–41(1926); *Physik. Ber.* **7,** 378 (1926).—W. uses his own and Coolidge's expts. In tubes contg. some gas, the secondary cathodic rays, which cause the fluorescence and the heating of the glass wall, are particles of the primary cathodic radiation which were not transformed into x-rays on the anticathode These cathodic rays are not reflected; they are scattered. In gas-free tubes, a similar explanation will account for the production of these secondary cathodic rays. The potential fall at the glass surface was detd. with lycopodium dust, and found to be different for the two sorts of tubes. In tubes contg. gas the glass potential approaches the positive-pole potential; in gas-free tubes it approaches the potential of the negative pole. A. L. HENNE

The relation of hydrolysis to the validity of Beer's law. R. C. GIBBS AND C. V SHAPIRO. Cornell Univ. *Proc. Nat. Acad. Sci.* **14,** 694–700(1928).—Because of the change in the character of the absorbing centers the absorption spectra of aq. or alc solns. of substances which may undergo hydrolysis, or alcoholysis, do not follow Beer's law. This has been shown by a study of the spectra of a no. of phthaleins and related compds. (cf. *C. A.* **20,** 1989; **22,** 1755, 2109). As the concn. of base in the soln. was increased new bands characteristic of the ions appeared in both the visual and ultra violet regions. At high concn. of base, represented in phenolphthalein by a ratio of 232 to 1 mols. of KOH to phthalein, the absorption was independent of the concn. used, thus indicating that hydrolysis was completely prevented. For the smaller ratio of 23 to 1, the absorption is no longer independent of the concn. but is partly influenced by the presence of the mols. of the phthalein in the lactoid form. Analogous results were obtained for resorcinolbenzein, fluorescein and sulfonefluorescein. Since the latter is the stronger acid, its neutral salt is least susceptible to hydrolysis and, therefore, the change in the spectra accompanying a change in concn. is the least. For these 3 compds., in the presence of 1 or 2 mols. of KOH, the bands are characteristic of both the free compd. and the ion and no regular relationship exists between the disappearance of the former and the appearance of the latter. For 20 mols. of KOH all of the neutral bands disappear and the perfect accord in the positions of the bands due to the ions shows the similarity in internal structures. In studying fluorescent media the safest procedure would be to have sufficient excess of alkali present so that no hydrolysis can take place. This can readily be detd. by preliminary observations on the absorption of the soln. at several concns. H. F. JOHNSTONE

Statistical calculation of the Rydberg correction of the s-term. E. FERMI. *Z. Physik* **49,** 550–4(1928).—See *C. A.* **22,** 3826. A. J. KING

A statistical determination of the M-Röntgen terms. F. Rasetti. *Z. Physik* **49**, 546–9(1928).—By the application of his theory of gas degeneration to the electrons in atoms Fermi (*C. A.* **22**, 2314) has shown how a statistical value for the elec. potential of the inner atom can be obtained. The knowledge of these potentials permits the *evaluation of the energy of the quantum state of the electrons in the atom.* R. has calcd. the M-Röntgen terms whose values agree well with the empirical values and serve as a satisfactory proof of the Fermi inner potentials. A. J. King

Quantitative test of Hund's theory of doublet bands of the OH type. E. C. Kemble and F. A. Jenkins. Harvard Univ. *Phys. Rev.* **29**, 607(1927).—Multiple electronic levels in mols are due to different orientations of the electron spin vector relative to the internuclear axis. At low speeds the component of the spin vector parallel to the nuclear axis and at high speed that parallel to the resultant angular momentum is quantized. The resulting distortion of the mol is manifested by bands of doublets or triplets. The effect of the distortion on the rotational term was tested for doublets and observations confirm the theory and check the formula $B:B = (1 \mp z)^2h/8\pi^2 I \pm z^2\Delta_0$, where Δ_0 = term difference for the doublet at zero rotation and $z = h/(8\pi^2 I\Delta_0 - 2h \pm 2h)$, the upper sign going with the lower level of the pair. S. L. B. Etherton

Spectroscopic demonstrator for the exhibition of emission, continuous, and absorption spectra. H. T. Stetson and H. W. Geromanos. *J. Optical Soc. Am.* **16**, 293–4(1928).—The continuous spectrum is produced by an incandescent electric lamp supported 1 ft. from a direct-vision spectroscope. The interposition of a Na flame gives rise to an absorption spectrum, and the latter flame alone to the two Na lines. B. C. A.

"Rainbow" spectra. Robert Saxon. *Chemistry and Industry* **47**, 712–3(1928); cf. *C. A.* **21**, 3829.—There is a bright spectrum from the near side of a highly polished rod when a converging or a diverging beam of light is used. This might be due to groove scratches on the surface acting as a grating. The rods were therefore polished by turning in a lathe and finishing with fine crocus. Thus any grooves must be circular. In each case the spectrum is due to "edge interference" from the slit and lens and the rod merely assists the dispersion. The color of the rod influences the resultant spectrum, Cu killing the blue in the spectrum. To eliminate dazzle the rays should impinge as near as possible to the focus. Rods of highly polished stainless steel are as good as silver, which is too soft. By using a thin tube the absorption effects of various colored materials have been experimented with, and, as each color in the spectrum is given separately, the presence or absence of certain colors is an indication of color strength. Thus with one tube, color strength in solns. can be computed. S. L. B. Etherton

Revision of Rowland's preliminary table of solar spectrum wave-lengths with an extension to the present limit of the infra-red. Charles E. St. John, Charlotte E. Moore, Louise M. Ware, Edward F. Adams and Harold D. Babcock. *Carnegie Inst. Washington Pub.*, **396** (*Papers of Mount Wilson Observatory*, **3**), xxi + 238 pp. (1928).—Fifty-seven elements have been identified in the sun; 32 of these are ionized in part or whole. Of the remaining 35 elements not yet identified in the sun, 17 may be regarded as possible, and 18 as doubtfully possible of detection. A bibliography is also given. Joseph S. Hepburn

Filtration of arc and spark lines in magnetic field by using disruptive discharge in vacuum. Hantaro Nagaoka and Tetsugoro Futagami. Inst. Phys. Chem. Research, Tokyo. *Proc. Imp. Acad* (Japan) **4**, 195–7(1928).—The method of sepg. arc and spark lines in a spectrum by using the disruptive discharge in a strong magnetic field gives ambiguous lines in some cases, owing to the resistance of the air to the motion of the ions. This can be prevented by using the discharge in a vacuum. An app. is described by means of which this can be studied. C. J. West

Transmission and reflection of gold and silver films. W. V. Houston and G. Moore. *J. Optical Soc. Am.* **16**, 174–6(1928).—Measurements of the reflecting power and transmission of sputtered films of Au and Ag as a function of the wave length and thickness were made to det. the most suitable coating for the mirrors of interferometers. Between 5000 and 6000 A. U. Au and Ag are equally good. Above 6000 A. U. Au is superior, since for the same reflecting power the transmission is higher. Below 5000 A. U. Ag is much superior to Au. B. C. A.

Demonstration of partial frequencies in light waves of periodically varying intensity. E. Rupp. *Z. Physik* **47**, 72–88(1928); *Science Abstracts* **31A**, 373.—The everyday effect in the technic of elec. oscillations of superimposing a modulation wave on a fundamental is here extended in a new manner to light waves. The light of the green Tl line is modulated by means of elec. waves of wave length from 100 to 24 cm. by the use of the Kerr effect, and the presence of partial frequencies is demonstrated by suit-

able app., which includes a resonance lamp and an absorption tube contg. Tl vapor. H. G.

Absence of broadening of spectral lines after reflection. Y. ROCARD AND P. DE ROTHSCHILD. *Compt. rend.* **186**, 313-5(1928); *Science Abstracts* **31A**, 367.—The authors consider the theory of the broadening of spectral lines owing to the thermal agitation of the reflecting atoms, which, in consequence of the Doppler-Fizeau effect, modifies the wave length of the reflected light. R. and R. have caused a beam of light to be reflected by 6 or 8 silvered mirrors successively at 45° before entering a Michelson interferometer. In the hope of increasing the velocity of thermal agitation of the diffracting atoms, expts. were made in which some of the silvered mirrors were replaced by polished Al ones. Various fine lines were employed, and the rings at infinity seen in the interferometer with large differences of path were compared with those produced by direct light suitably reduced in intensity by an optical wedge. No change in the visibility of the rings was observed. Calcns. have shown that the method would have made evident $^1/_{200}$ of the actual thermal energy if this had produced the expected Doppler effect. It is suggested that either the diffraction of the waves by the atoms does not constitute the real elementary phenomenon, or that there is a kind of linking between neighboring atoms so that their vibrations are synchronized. H. G.

Light excitation of metallic spectra by means of the metastable state in atoms of noble gases. F. PASCHEN. *Sitzb. preuss. Akad. Wiss.* **1927**, 207-13.—Under certain conditions in a discharge tube, atoms of the rare gases exist in a metastable condition for a relatively long period (10^{-2} sec.). By means of collisions, they can give up energy corresponding with the following voltages: He 19.72. Ne 16.6, A 11.5. When the discharge tube contains a small proportion of foreign atoms, liberated by heat or elec. sputtering from Al, Mg, Zn or Cd, the spectra of these metals are excited by collisions between atoms of metal and metastable rare-gas atoms. In the neg. glow, neutral atoms are excited and a considerable no. of simple, positively charged ions of the metallic foreign substance also make their appearance spectroscopically manifest; thus, in addn. to arc lines, all the terms of the first spark spectrum are excited provided that they exceed T, where $T = T_0^+ - E$, T_0^+ being the deepest term of the first spark spectrum of the metal and E the excitation voltage of the rare gas. In the pos. glow, more neutral atoms are excited than in the neg. glow. In a side tube, branching from near the pos. column, it was possible to detect metastable Ne atoms (by absorption of the 6402 A. U. Ne line) at a distance of 2 cm. from the pos. light. In this region of the tube, neutral atoms of metal vapor alone undergo excitation. Only such terms in the first spark spectrum as are greater than T' make their appearance, T' being defined by $T' = T_0 + T_0^+ - E$, T_0 being the fundamental term of the arc spectrum. Excitation therefore seems to be due to collisions, and the emission is much more intense than in expts. using electronic impacts. The interpretation is fully substantiated by the exptl. data. B. C. A.

Electrified spherical films and fine structure of spectral lines. L. DÉCOMBE. *Compt. rend.* **186**, 68-70(1928); *Science Abstracts* **31A**, 340.—To account for the fine structure of spectral lines, Sommerfeld has advanced a remarkable explanation based on the consideration of pseudoelliptic orbits with sep. radial and azimuthal quantizations, but postulating, according to Bohr's process, a jump of electrons from one orbit to the other. It is a simple matter to liberate the theory from this strange postulate; all that is needed is to bring in as a factor the pulsations of the orbital electrons (assimilated to elastic spherical films) and to identify the luminous frequency with that of the beats intervening between the pulsations of 2 electrons moving in 2 different orbits, as has already been done with circularorbits (*C. A.* **22**, 3833). In the present case, however, one must consider the vibratory frequency of the electronic film as a function not only of the kinetic energy (constantly variable when the orbit is not circular), but of the total energy which, on the contrary, remains const. for the whole duration of the motion. On this condition alone can the frequency of the beats have a fixed value. The treatment of the problem is mathematical. H. G.

Highly accurate method for interferometric wave-length determinations, and its application to a preliminary determination of krypton lines for a German standard meter in terms of light waves. A. P. WEBER. *Physik. Z.* **29**, 233-9(1928).—In view of the use of interferometric methods in fixing standards of length, the relative merits of the Fabry-Perot etalon and the Koster abs. interference comparator methods have been studied at the Physikalisch-Technischen Reichsanstalt. The Kr spectrum possesses advantages over the Cd spectrum in that the latter shows only one entirely suitable line, the standard red line, whereas several lines are available in the discharge from pure Kr. The following wave lengths have been measured relative to the Cd

line 6438.5033 A. U. (in air at 20°, 760 mm., and 10 mm. moisture): green Cd, 5085.8490, red Kr, 6456.3241, yellow, 5870.9463, yellowish green, 5649.5924, violet, 4502.3790, green, 5400.5919, the 2 lines last named being measured relative to the other Kr lines. Pending further investigations in different countries on the Kr yellowish green line, the use of the Cd red line as a standard is continued. B. C. A.

Undulating theory of two electron orbits. A. W. Conway. *Proc. Roy. Irish Acad.* **38,** 18–28(1928); *Science Abstracts* **31A,** 341–2.—Two-electron orbits in which the 2 electrons rotating about a nucleus of charge $2e$ repel each other with a force varying as the inverse cube of their distance, are dealt with by Schrödinger's method, and the results obtained compared with those given previously (*C. A.* **21,** 3541) on the basis of the Bohr-Sommerfeld-Wilson quantization principle. Certain differences in the spectral terms given by the 2 methods are recorded. H. G.

Construction of wave-length scales for spectrograms. G. Barr. *Trans. Optical Soc.* (England) **29,** 22–7(1928).—A method is described by which an approx. scale of wave lengths may be projected geometrically on to a spectrogram from a uniformly divided scale when a no. of easily recognizable lines have been identified. B. C. A.

The titanium oxide bands. A. Christy and R. T. Birge. *Nature* **122,** 205 (1928).—The fine structure analysis of the blue-green Ti bands (cf. *C. A.* **22,** 4063) has now reached the point where it is possible to draw certain definite conclusions regarding the mol. responsible for the radiation of these bands. These conclusions are based on a complete verification of the combination principle, using some 1500 lines measured in the 3 bands 0-0, 1-0 and 0-1 with wave lengths at 5167 A. U.; 4955 A. U. and 5448 A. U., resp. Each band consists of 3 R and 3 P branches. The new fact that the individual bands have a triplet structure is practically certain proof that they are due to a mol. with an *even* no. of electrons, *i. e.*, neutral TiO. The values of the moments of inertia for the upper and lower levels are $(56.76 \pm 0.03) \times 10^{-40}$ and $(51.87 \pm 0.03) \times 10^{-40}$, resp., corresponding to a nuclear sepn. of 1.694×10^{-8} cm. and 1.619×10^{-8} cm. W. F. Meggers

Continuous absorption in sodium vapor. B. Trumpy. *Z. Physik* **47,** 804–13 (1928).—T. has already shown that there is good agreement between his results with the chief line series of Na and Li and the requirements of Schrödinger's theory. The theory not only describes the discontinuous line spectrum but also predicts the structure and intensity of the continuous spectrum arising with smaller wave lengths at the series limit. The coeff. of absorption of the boundary continuum falls rapidly with diminishing wave length until at about 2300 A. U. it is half the value of the series boundary. The app. consists of an Fe tube with quartz windows at the end; it is heated by the secondary current of a small transformer. The const. source of light was the spark between 2 disks rotating at const. speed. The exptl. results are compared with the theory of Sugiura. At the series boundary, the boundary absorption passes continuously into line absorption and an apparent fall in absorption with increasing wave length near the boundary is connected with the imperfect resolving power of the spectrograph. At high temps. a continuous absorption between the chief lines of the series was observed as well as at the boundary continuum. However, the absorption was depressed with falling temp. S. L. B. Etherton

Fine structure of sodium D lines. L. Dobrezov and A. Terenin. Opt. Inst., Leningrad. *Naturwissenschaften* **16,** 656(1928).—The observations of Schüler (*C. A.* **22,** 3356) were confirmed by measurements of luminescent Na atom rays by a 30-cm. Lummer plate perpendicular to the ray, reducing the Doppler effect to 6° abs. temp. On splitting of D_1 and D_2 a double set of doublets was found of 0.01 A. U. order. Ghost pictures were excluded. B. J. C. van der Hoeven

Energy distribution in the continuous spectrum of the aluminum spark under water. Ilse Wyneken. *Ann. Physik* **86,** 1071–88(1928).—The energy distribution in the spectrum of the underwater spark between Al electrodes was detd. by a photographic-photometric comparison with the known energy distribution of the C arc. At 2850 A. U. there is a definite max., the intensity being approx. $3^1/_2$ times as great as in the neighborhood of 4500 A. U. On the assumption of a purely thermal radiation this would correspond to 10,000° K. However, the black-body radiation curve for this temp. is much flatter than the exptl. curve obtained. A comparison of Cu with Al gave no indication of a dependence upon electrode material. The falling off of the curve in the extreme ultra-violet is not due to absorption by H_2O. A bibliography is included. W. W. Stifler

Measurement of the life period of metastable mercury atoms. T. Asada, R. Ladenburg and W. Tietze. Kaiser Wilhelm Inst., Berlin-Dahlem. *Physik. Z.* **29,** 549–50(1928).—Previous measurements used atoms generated electrically. Hence

there is an objection that ions of relatively long life period are also formed and that after a certain life period part at least of the demonstrated metastable atoms are produced from them without having overlived their period of existence. Optical excitation of metastable atoms avoids this objection. Such excitation is based upon the stepwise principle discovered by Fuchbauer. The metastable $3P_1$ atoms are generated by the ultra-violet resonance line 2537 and are photographed on a rotating-disk app. described. Previous measurements gave a life period of 15×10^{-4} sec. It now seems possible to investigate the influence of external conditions upon the life period and to test Foote's rule. S. L. B. ETHERTON

Spark spectra of mercury vapor. JOSEPH VALESEK. *J. Optical Soc. Am.* **17**, 102-6(1928).—In 1923 L. and E. Bloch (*J. de phys.* **4**, 333 (1923)) published a list of 300 spark lines of Hg which were obtained by observing an electrodeless discharge. As the length of the spark gap in the primary of the Tesla coil increased, the spark lines could be sepd. into 3 groups which were designated as the E_1, E_2 and E_3 spectra. The present investigation deals with the location of the E_3 radiation potentials. These potentials probably give the energy required to produce excited and ionized Hg^{+++}. With app. practically like that described before (*Phys. Rev.* **29**, 817 (1927)) the photographic density of various lines was obtained as a function of the accelerating potential. Crit. potentials were located at 108 and at 118 v. Intensity measurements show that these lines are excited by a single impact because the intensities increase in the same proportion as the electron current, whereas if 2 collisions were required to bring the atoms into the initial excited state, the no. of excited atoms, and therefore the intensity of the lines, should increase as the square of the current. W. F. MEGGERS

Intensity changes in mercury lines under varying discharge conditions. TAKE HORI. *Z. Physik* **49**, 259-68(1928).—Intensity curves of Hg lines in high and low voltage arc are given, and it is concluded that the changes are due to differences in electron velocity. GREGG M. EVANS

Remark on the work of Hori on the intensity of mercury lines. E. FUES. *Z. Physik* **49**, 269(1928); cf. preceding abstr.—F. prefers selective direction of colliding electrons, rather than velocity, as a cause of intensity changes. GREGG M. EVANS

New hydrogen-mercury bands in the ultra-violet. H. JEZEWSKI. *Przemysl Chem.* **12**, 492-3(1928).—The structure of heretofore unobserved bands of a mixt. of H_2 and Hg vapor excited to radiation by means of oscillating discharges is analyzed and interpreted. These bands extend from $\lambda = 2537$ to $\lambda = 2190$ A. U. A. C. Z.

Duration of Stark effect in hydrogen and nitrogen. H. KERSCHBAUM. *Ann. Physik* **84**, 930-8(1927).—The duration of the Stark effect in $H\beta$ and $H\gamma$ has been detd. from observations on canal rays and is found to be const.; the duration of the negative Ni band 4278 A. U. is 2.54×10^{-8} sec., *i. e.*, approx. twice that of the spark-excited band. B. C. A.

The second-order Stark effect of hydrogen. H. RAUSCH VON TRAUBENBERG. Deutsche Univ., Prag. *Naturwissenschaften* **16**, 655-6(1928).—The Stark effect of first and second orders was observed in fields of 420,000 v. per cm. The method was the one of Stark with sep. field, the canal rays entering through a 0.1-mm. slit in the cathode of the elec. field. The second-order effect (red shift of the cleavage components) is represented in 6 graphs for various components of $H\gamma$. The Schrodinger values (larger than those of the old quantum theory (Wentzel, *Z. Physik* **38**, 518 (1926), Waller, *C. A.* **21**, 1059) were in agreement with the data. The proportionality with F^2 (F is field) was well borne out. B. J. C. VAN DER HOEVEN

Some unclassified lines of oxygen in the ultra-violet. J. J. HOPFIELD. Univ. of California. *Phys. Rev.* **29**, 923-4(1927).—Although among the strongest in the O spectrum, the line 1152 A. U. and the triplet 988.67 A. U., 990.13 A. U and 990.73 A. U. have not yet been fitted into series. It is suggested that these are due to O I, and the triplet may be an unresolved group similar to one in S at approx. 1480 A. U., which contains 8 lines, with the normal triplet sepn. occurring twice. W. W. S.

The NH band and the dissociation energy of nitrogen. E. GAVIOLA. Johns Hopkins Univ. *Nature* **122**, 313-4(1928).—Using R. W. Wood's arrangement for the optical excitation of Hg vapor (*C. A.* **21**, 3830), G. has observed the NH band at 3360-70 A. U., when about 4 mm. of N_2 and a few thousandths of a mm. of H are admitted to the quartz tube contg. the excited Hg vapor. The intensity of the band is proportional to the square of the intensity of the exciting light. That is, the concn. of atomic N must be proportional to the sq. of the intensity of the arc, or to the sq. of the no. of excited Hg atoms. This relation can be interpreted if we assume that at. N is formed by 3-body collisions of N_2 mols. with two excited Hg atoms, $N_2 + 2Hg' \longrightarrow 2N + 2Hg$. However, if this is the mechanism, the max. energy available for the dissocn

of N_2 is 9.8 v., coming from the 2^3P_1 Hg atoms with 4.9 v. energy. It appears, therefore, that the dissocn. energy of N_2 is less than, or about, 9.8 v., and not 11.4 v. as was calcd. by Sponer and Birge. R. J. HAVIGHURST

The structure of the spectrum of ionized argon (A II). T. L. DE BRUIN. Univ. Amsterdam. *Verslag Akad. Wetenschappen Amsterdam* **37**, 553–61(1928); cf. *C. A.* **22**, 2326.—On the basis of the Heisenberg, Pauli and Hund schemes are derived 3 base terms of the ionized A atom, 3P and metastable 1D and 1S. In the spectrum 180 lines were classified; 46 out of 59 theoretical energy levels were identified; the others are outside the visible spectrum. The ionization potential was detd. to be 27.75 ± 0.05 v. A detailed photograph and tabulated data are presented. B. J. C. VAN DER HOEVEN

The fundamental vibration quantum of gaseous alkali halides. K. SOMMERMEYER. Univ. Gottingen. *Naturwissenschaften* **16**, 653–4(1928).—In thick layers (15 to 20 cm.) regular distances of diffuse bands (3 to 10) in the long wave range of the alkali halide absorption spectrum could be observed. By proper pressure and temp. regulation up to 25 members were found over several hundred A. U.; these bands follow the continuous spectrum, the distances converge towards red. The source is assumed to be vibration of normal mols. at the temps. used of 750° to 1100°. Good agreement with Born and Heisenberg's fundamental vibration quantum (*Z. Physik* **23**, 388 (1924)) was found For CsI also higher vibrations were examd. Only for high dispersion fine structure (for KI and NaI) is noticeable, indicating a small dissocn. energy of the excited state (atom bond). From this apparent practical equality of excitation energy and dissocn. energy of the halides the latter can be calcd. from the short-wave bands. The results agree fairly well with those obtained in other ways. B. J. C. v. D. H.

The first ultra-violet characteristic frequencies of some simple crystals. R. HILSCH AND R. W. POHLE. *Z. Physik* **48**, 384–96(1928).—The ultra-violet absorption spectra of *TlCl, TlBr, TlI*, $PbCl_2$, PbI_2, *AgI* and *I* have been detd. Thin sheets of approx. 10 μ thickness were prepd. by pressing the molten crystal between amorphous quartz plates. Thicknesses were detd. by interference methods The absorption maxima occur at the following wave lengths (in μ): TlCl, 245 and 216; TlBr, 273 and 239; TlI, 289, approx. 250 and approx. 220; $PbCl_2$, 271 and 219; PbI 303 and 278 The max. for I is at approx. 350 with decreasing absorption toward shorter wave lengths at least down to 200 μ. The absorption spectra of two *alkali halide "phosphors,"* KI + Tl and KI + Pb were detd. and compared with those of pure TlI and PbI. The maxima of the various alkali halide "phosphors" in which Tl and Pb are the "active metals" do not exactly coincide with those of the pure Tl and Pb halides, yet the agreement in the positions of the first bands is so good and the maxima are so much sharper in the "phosphors" that their use for the detn. of absorption maxima is suggested as a possible exptl. simplification Care must be used in the choice of cation in the solvent material (*e. g.*, KI in the above instances), since it must be sufficiently chemically and crystallographically similar to the "effective metal" cation (*e. g.*, Tl) to produce the increased sharpness without displacing the band. R. L. HERSHEY

The ultra-violet absorption of iodides in solution. GUNTER SCHEIBE. *Sitzb. phys. med. Sozietat Erlangen* 58–9, 2 pp.; *Chem. Zentr.* **1927**, II, 2151; cf. *C. A.* **20**, 0130; **21**, 1932 –The absorption by iodides in H_2O and alcs. is examd. to 186μμ. In aq. soln., LiI, NaI, KI, MgI_2 and SrI_2 have a max. of absorption at 225μμ, a min. at 200μμ, and a 2nd max. at about 192μμ. In EtOH, the 1st max. is at 216μμ, the min. at 204μμ, while the 2nd max. is unchanged as compared with H_2O. The height of the max., referred to the same I-ion concn. is always the same; therefore the absorption of the I ion is identical in iodides with an alkali or an alk. earth as the base. In aq. soln. of ZnI_2 and CdI_2, the 2 max. and the min. have the same height as in the case of the alkalies and the alk. earths. In alc. soln., the absorption curve for ZnI_2 is displaced towards the ultra violet and lowered by a half. With CdI_2 in alc. soln., a displacement towards the red occurs, which is still more distinct with HgI_2 in EtOH. Thus with Cd and Hg in EtOH, a new kind of linkage appears. According to these findings, the change between homopolar and heteropolar linkage in alc. soln. may be assumed to be at the transition from Zn to Cd. G. SCHWOCH

The scattering of light by free electrons according to Dirac's new relativistic dynamics. O. KLEIN AND Y. NISHINA. Universitets Inst. for teoretisk Fysik, Köbenhavn *Nature* **122**, 398–9(1928). –K. and N. undertake calcn. of intensity of light scattered by an electron under the influence of a plane, unpolarized, monochromatic wave train, based on D.'s development of the original Dirac and Gordon treatment. K. and N.'s result is: $I = I_0 \frac{e_4}{2m^2c^4r^2} \cdot \frac{(1+\cos^2\theta)}{\{1+\alpha(1-\cos^2\theta)\}^3} \cdot \left[1 + \alpha^2 \frac{(1-\cos\theta)^2}{(1+\cos^2\theta)\{1+\alpha(1-\cos\theta)\}}\right].$

where I is intensity at distance r from the electron of the light due to a Compton process where the secondary light quantum is emitted in a direction forming an angle θ with the incident beam of intensity I_0 and frequency ν, and $\alpha = h\nu/mc^2$. This formula differs from the corresponding one of the older theory by the last factor (in square brackets) and the deviations of the formulas are of the order of α^2, while the earlier expression differs from J. J. Thomson's classical expression by quantities of the order of α. For $\lambda = 0.022$ A. U., where D. had compared his formula with Compton's measurements the deviations are large. The above formula leads to one for s, the scattering coeff., due to the Compton effect of a substance contg. N electrons per unit vol. in which if α is small compared to unity, $s = (8\pi/3)(Ne^4/m^2c^4)(1 - 2\alpha + (26/5)\alpha^2)$, which differs from D.'s formula in that D.'s term $(21/5)\alpha^2$ is here replaced by $(26/5)\alpha^2$, and the order of differences is about α^2, as before. But for $\alpha = 1$ the values are about 50% higher than D's. For small values of α, the differences are small. If K. and N.'s formula is used for calcg. λ of cosmic penetrating radiation the calcd. values are considerably smaller than those hitherto assumed. A. P. SACHS

Negatively modified scattering. M. N. SAHA, D. S. KOTHARI AND G. R. TOSHNIWAL. Allahabad University. *Nature* **122,** 398(1928).—Einstein and Ehrenfest (cf. *C. A.* **18,** 627) deduced thermodynamically a scattering of light by the particles of the assembly which it traverses. Smekal (cf. *C. A.* **18,** 2834) pointed out, that light of frequency ν, after scattering, would possess frequencies ν, $\nu + \nu_k$ and $\nu - \nu_k$, where $h\nu_k$ is the energy diff. between the excited state and the normal state of the particles causing the scattering. Raman and Krishnan (cf. *C. A.* **22,** 1907) have confirmed Smekal's prediction. S.'s theory explains the Wood resonance spectra of vapors of Na, K and halogens. Anti-Stokes lines (*i. e.*, those of shorter λ than the original light) are equally spaced and are due to neg. modified scattering, which is a phenomenon intermediate between pure scattering (as by fog particles which cause scattering but remain themselves physically unchanged) and pure absorption. This explanation should be capable of extension to free electrons and will probably afford an easy explanation of the origin of bright and broad bands in spectra of Novae, and of winged lines in solar spectrum. A. P. SACHS

Wave-length shifts in scattered light. ARTHUR E. RUARK. Mellon Inst., Pittsburgh. *Nature* **122,** 312-3(1928).—It is suggested that the new type of radiation emitted by org. liquids when illuminated with the light of a Hg arc, described by Raman and Krishnan (*C. A.* **22,** 2884), be investigated with regard to the question of the existence of a time lag between reception of the incident light and emission of scattered radiation of modified wave length. Such an investigation might decide whether the secondary radiation is a fluorescent emission following the absorption process after a finite interval, or the scattered light of modified wave length predicted by Kramers and Heisenberg in their correspondence principle treatment of dispersion. R. J. H

Polarization of resonance radiation and breadth of spectral lines. A. ELLETT. State Univ. of Ia. *Proc. Iowa Acad. Sci.* **34,** 283(1927).—Observations of the polarization of the D line resonance radiation of Na indicate that the transition probabilities for the various components of the Zeeman pattern are substantially in agreement with the predictions of the so-called sum rule. Observations in relatively strong fields show the effect of non-uniform distribution of intensity in the exciting spectral line. The assumption that the distribution of energy in the exciting line is due practically entirely to Doppler effect leads to equations for the variation of polarization with field strength which are well verified experimentally. Any broadening of the line by collision or by a coupling effect is evidently small in comparison with the Doppler breadth. W. G. GAESSLER

The aurora and its spectrum. J. C. MCLENNAN. *Proc. Roy. Soc.* (London) **A120,** 327-57(1928).—Bakerian lecture delivered June 28, 1928. W. F. MEGGERS

Line spectra and the periodic arrangement of the elements. SAUL DUSHMAN. *Chem. Reviews* **5,** 109-71(1928). W. F. MEGGERS

An investigation of the absorption spectra of water and ice, with reference to the spectra of the major planets. J. C. MCLENNAN, R. RUEDY AND A. C. BURTON. *Proc. Roy. Soc.* (London) **A120,** 296-302(1928).—The principal unidentified bands in the spectra of the 4 planets, Jupiter, Saturn, Uranus and Neptune, are at 5430, 6190 and 7200 A. U. Photographs of a continuous spectrum were made through columns of water 4 m. and 21.5 m. long; they show a diffuse absorption band with its sharper edge at about 5990 A. U., extending to about 6350 A. U., a second band extending from about 6560 to 6700 A. U. and a third band beginning at about 7000 A. U. The absorption of ice was also investigated with lengths up to 14 m.; the absorption bands appear to be shifted toward the longer wave lengths. It is believed that the red absorp-

tions in the spectra of the 4 major planets can be attributed to water in the liquid state but the band in the green at 5430 A. U. still remains unidentified. W. F. MEGGERS

The absorption spectrum of iodine in ethyl alcohol. ALAN BATLEY. *Trans. Faraday Soc.* **24,** 438–52(1928).—The results of investigations by previous workers on the absorption spectrum in the visible and ultra-violet regions of I dissolved in EtOH show a marked lack of agreement. It is considered important to ascertain the actual cause of the discrepancies, and to det. the true absorption curve. The ultra-violet and visible absorption exhibited in solns. of I_2 in EtOH is now investigated (250$\mu\mu$ to 720$\mu\mu$) by means of a quartz spectrograph and sector photometer. Measurements are made with ozone-satd. EtOH which decomposes the H iodides as formed. The true absorption curve shows only one max. of wave length 447$\mu\mu$ with general absorption in the far ultra-violet. The max. recorded at 370$\mu\mu$ and 290$\mu\mu$ by previous observers are proved to be due to the formation of HI_3 in the soln. The HI_3 has been isolated in the solid form upon gelatin, and is shown to exhibit in this state, an absorption max. at 368$\mu\mu$. In general there are, in solns. of I_2 in EtOH, opposing reactions—(a) the photochem. reaction giving HI and HI_3 and (b) the photochem. oxidation of H iodides by dissolved O_2, the relative velocities of the reactions being influenced by various factors. Thus, the absorption curve exhibited will depend on the method and speed of observation, on the light source used, on the water content of the solvent, on the diln. of the soln. and on whether the solns. were exposed to daylight, either before or during examn. W. F. MEGGERS

Further investigations of the spectrum of singly ionized carbon (C II). A. FOWLER AND E. W. H. SELWYN. *Proc. Roy. Soc.* (London) **A120,** 312–26(1928).—In a previous paper (*C. A.* **18,** 1612) it was shown that a considerable number of lines attributed to singly ionized C could be arranged in a regular system of doublet series. Numerous lines which appeared to belong to C^+ remained unclassified, but further analysis of the spectrum has been greatly facilitated by subsequent theoretical developments. In accordance with Hund's theory, quartet as well as doublet terms are to be expected, and several of these additional terms have now been identified. The present communication gives an account of the newly classified lines, and includes improved measurements for some of the lines previously considered. A list of 160 lines, 7236 to 534 A. U., attributable to C^+, is given; 110 of these have been classified. W. F. MEGGERS

Structure of induction spectra of rare gases. A. T. WILLIAMS. *Univ. nac. La Plata, estudio ciencias* No. **82,** 253–81(1928); *Science Abstracts* **31A,** 376.—The purpose is to establish the usefulness of excitation by the induction method to sep. different orders of the spectra of any element. In the spectra of A is established the correspondence between theoretical terms and Meissner's terms in order to the arrangement of lines in multiplets. There is also classified with Meissner's terms 2 new lines, 3354, ($1s$ – $6p_8$) and 3355, 4($1S_3$ – $6p_3$). In the spectra of Kr there are classified 49 const. sepns. and 2 groups of lines. In the spectra of X the const. sepns. obtained are 195, and there are also several groups of lines. The validity of the method of Bloch and Déjardin (*C. A.* **18,** 1432) is considered. H. G.

Quantum theory of the Ramsauer effect. J. R. OPPENHEIMER. *Proc. Nat. Acad. Sci.* **14,** 261–2(1928).—The Ramsauer effect can be accounted for by consideration of electronic resonance and spin. Two first-order cross-sections for the elastic collision of an electron and a hydrogenic atom can be calcd., corresponding with initial orbital wave-functions, resp., symmetric and anti-symmetric in the coördinates of the impacting electron and the at. electron. The symmetric wave-function gives a greater cross-section than that calcd. without resonance, while the anti-symmetric function gives a cross-section vanishing from some small velocity for each angle of deflexion. The total cross-section shows a sharp min. at about 1 v. In the general case, both symmetric and antisymmetric wave functions will occur, but for atoms having only paired electrons (*e. g.*, He, A, CH_4) the cross-section is given by the anti-symmetric function alone and may, therefore, pass through a min. for sufficiently low velocities. For any particular case the whole problem must be solved. Minima in cross-sections have been observed for A and Kr. B. C. A.

Study of the spark spectra of sulfur, selenium and tellurium in the Schumann region. P. LACROUTE. *J. phys. radium* **9,** 180–4(1928).—Spectra of S, Se and Te between 1235 and 2200 A. U. by means of a spectroscope with a grating in vacuum. Light is produced by discharge without electrodes in rarefied vapors. Tables are given. L. D. R.

Change of fluorescence in ultra-violet light. MAX HAITINGER AND VIKTOR REICH. *Z. angew. Chem.* **41,** 982–3(1928).—Ether exts. of wines showing fluorescence on filter paper strips when sealed in tubes contg. air or CO_2 do not lose their fluorescence either

in the light or dark. After several weeks in the light, however, the color diminishes in either air or CO_2. Other substances on paper, salicylic acid, glycine, fluorescein and wine ext. lose fluorescence entirely in Hg arc light. Filtering the light by glass weakens the original color. G. B. TAYLOR

Ultra-violet absorption spectrum of chlorophyll in alcoholic solution. ELSA LEWKOWITSCH. Imperial College of Science and Technology, London. *Biochem. J.* **22,** 777-8(1928).—Absorption maxima are shown at 4200 and 3250 A. U. The curve rose steeply below a wave length of 2400 A. U. BENJAMIN HARROW

The luminescence of solid nitrogen under cathode-ray bombardment. J. C. McLENNAN, H. J. C. IRETON AND E. W. SAMSON. Univ. of Toronto. *Proc. Roy. Soc.* (London) **A120,** 303-11(1928); cf. *C. A.* **21,** 3831.—The previous app. was improved by the use of a new Coolidge tube capable of yielding high-velocity cathode rays outside of the generating tube. The stream of electrons impinged on solid N_2 frozen in liquid H_2. It produced a bright yellow-green luminescence The N_2 was produced from $NaNO_2$ and NH_4Cl, and dried over CaO and P_2O_5. Fresh N_2 was admitted every $^1/_2$ hr. during an expt. The spectrum was photographed from 2000 to 8600 A. U There are two distinct series of bands; a narrow set extending into the ultra-violet beginning at 2347 A. U.; and broad bands degrading into the red, beginning at 3105 A. U. Vegard's bands N_1, N_2, N_3, N_4 were also photographed. A new band was found at 6725 A. U., N_1, N_2, and N_4 could be seen in a hand spectroscope. N_1 vanished when the source of excitation was removed, while N_2 and N_4 had appreciable periods of decay. N_1 is thermoluminescent, since it appeared on warming the solid N_2. The decay curves for bands N_2 and N_4 are divided into 2 and 3 sections, resp., which obey the law $I(a + bt)^2 = 1$, where I is intensity, t is time, and a and b are consts. These lines may be due to adsorbed H_2, though proof is not conclusive. N_1, N_2 and N_4 are phosphorescent bands ARTHUR FLEISCHER

Triboluminescence and crystal luminescence. H. LONGCHAMBON. *Bull. soc franç. min.* **48,** 130-211(1925) - Triboluminescence is brought about by electrical radiation, which causes gas present at fractures to become luminescent The phenomenon is often complicated by phosphorescence and fluorescence. A no. of cases of crystal luminescence, where destruction of the crystal is accompanied by a rise of temp , are due to triboluminescence. In other cases, the effect is probably due to the existence of an elec. double layer at the crystal surface Triboluminescence does not occur when crystals are broken along their cleavage planes, if these are not perpendicular to an axis of pyroelectricity. B. C. A.

The fluorescence of hydrocarbons. A. ANDANT. *Chimie et industrie* **Special No.,** 267-9 (April 1928); cf. *C. A.* **21,** 2432 -Attempts to photograph the fluorescence spectra of liquid nonene and duodecene gave no appreciable image, even after 26 hrs.' exposure. With 3 hrs.' exposure fluorene and chrysene gave very characteristic curves. Under excitation by light of λ = 3132 A U., the fluorene spectrum showed 4 bands with max. intensity at 3805, 4040, 4340 and 4620 A. U , resp , and the chrysene spectrum 6 bands with max. intensity at 3950, 4040, 4150, 4340, 4690 and 4980, A. U., resp. Under excitation by light of λ = 2652 A. U. the chrysene spectrum shows only the last 4 above-mentioned bands. It should be noted that these 2 compds have 2 bands in common (4040 and 4340 A. U.); but it will require further work on other compds. to ascertain whether these bands are characteristic of compds. contg. 2 C H rings joined at their summits. A. PAPINEAU-COUTURE

The quenching of mercury fluorescence by the addition of gases. O. OLDENBURG. Göttingen Univ. *Z. Physik* **49,** 609-18(1928); cf. *C. A.* **22,** 1729. - The quenching of the resonance fluorescence of Hg vapor by N_2 and A is contrasted. These gases are equally effective in quenching at room temp., while at 750° A has five-fold the effect at 20° and N_2 does not act at all. This difference is due to the action of temp on the transition probabilities involved; a Hg atom on impact with A reverts to the normal state, while N_2 favors reversion to the metastable 2^3P_0 state (cf. Cario and Franck, *C. A.* **20,** 3126). H. R. MOORE

Fluorescence of mercury vapor. R. W. WOOD AND V. VOSS. *Proc. Roy. Soc.* (London) **A119,** 698-706(1928); cf. *C. A.* **22,** 1726.—Practically all of the stronger arc lines of the Hg atom are exhibited by Hg vapor when excited by the light of the Al spark, which can be absorbed only by the Hg mol. (band absorption). The intensity of these lines varies as the square of the intensity of the exciting light. With few exceptions, all of the arc lines increased in intensity with superheating, whereas the bands were practically unaffected in tubes free from H_2O vapor. Fluorescence of the vapor could not be obtained without simultaneous distn. if H_2O vapor was present. The

intensity of the Hg hydride bands increases in proportion to the H_2O content of the tube and to the degree of superheating. A. J. KING

The cathodophosphorescence of erbium in calcium oxide. SVEN FAGERBERG. *Ann. Physik* **86**, 435–46(1928).—The phosphorescent spectrum of Er in CaO is excited by an electron stream of a few tenths milliamp. intensity and a p. d. of 5000 v. It consists chiefly of line groups spread over the wave length domain 6800–3100 A. U. Superposed on this spectrum is a series of bright and diffuse continuous bands between 4100 and 3600 A. U., originating from the CaO substrate. H. R. MOORE

The phosphorescent combustion of sulfur. HARRY J. EMELÉUS. Imperial Coll. Sci., South Kensington. *J. Chem. Soc.* **1928**, 1942–50. —The ignition of S in O_2 occurs at 285–325°, but just below the ignition point the oxidation is accompanied by a bluish white luminescence. The phosphorescent flame changes into the normal flame as the temp. is raised. A search was made for oxides of S more volatile than SO_2, such as SO. The results indicate, however, that the sole products of the luminous oxidation are SO_2 and SO_3. Certain org. vapors inhibit the oxidation, and it is presumed their action consists in the quenching of active patches on the surface. H. R. MOORE

Phosphorescence of calcium tungstate induced by x-rays. F. E. SWINDELLS. *J. Optical Soc. Am.* **16**, 165–73(1928).—The rate of decay of a very phosphorescent sample of Ca tungstate, detd. photographically, was found to fit the Becquerel equation, $I^{-x} = a + bt$, from 30 sec. to 5 min. after exposure to x-rays The phosphorescence of this sample could be detected after 50 hrs. under conditions when the phosphorescence of normal Ca tungstate disappeared in 1 min. The intensity of the phosphorescence was found to be closely proportional to the product of the intensity of the x-rays and the time of exposure up to a limiting value, beyond which there was a negligible increase. B. C. A.

Quick and slow decay of luminescence of phosphors of various types of atoms. HELMUT MOSER. *Ann Physik* **85**, 687–710(1928). —With oxide phosphors the quick decay outweighs the slow decay, but with selenide phosphors the reverse is the case Sulfide phosphors, in general, show both processes equally strongly. The total emission shows a strong increase from O, S to Se as generic atoms and Ca, Sr to Ba as alk earth atoms. B. C. A.

Spectrum of calcium-strontium sulfide-samarium mixed phosphors. M. TRAVNIČEK. *Ann. Physik* **84**, 823–39(1927). —The phosphorescent system $[Ca_mSr_n]S$ — Sm + LiF has been investigated The Ca phosphor shows a sharp red emission line at 6058.6 A U., while the Sr phosphor has a corresponding line at 6036.8. With this emission as a criterion, it is found that the transition through mixts. of Ca and Sr is perfectly continuous as is to be expected if the phosphorescence center is a definite compd. Each component of the phosphor exercises some effect on the emission. In exactly the same way, the x-ray investigation shows that the lattice const. varies continuously. The cryst. nature of the sulfide diluent is of great importance in detg. emission from the phosphor, since lattice const. and frequency vary in the same sense. Freshly prepd. mixed phosphors are unstable, showing aging phenomena. Striking differences are recorded between fresh and one-year-old $MgSO_4$, $BaSO_4$ and MgO samarium phosphors both in respect of wave length and intensity of the emission bands. The interpretation of the results is discussed. B. C. A.

Spectrum of calcium-strontium sulfide-samarium mixed phosphors. M. TRAVNIČEK. *Ann. Physik* **85**, 645–6(1928); cf. preceding abstract.—A correction of a misstatement by Tomaschek (*C. A.* **22**, 1280). B. C. A.

Theory of extinction of photoluminescence in uranyl salt solutions. S. I. VAVILOV. Inst Physics and Biophysics, Moscow. *Z. Physik* **50**, 52–7(1928).—By mathematical treatment of a uranyl salt mol. as a Brownian particle a previous empirical formula, (cf. *C. A.* **22**, 3097) $\bar{t} = \alpha(\eta/c)$, is confirmed, where $\bar{t}$ is the av. time between activation of a mol. and its first extinguishing collision, η viscosity and c concn. of the soln. and α a const. Approx. values for α are given. V. accounts for a discrepancy of 50 times between his theoretical and empirical results by solvation of mols. G. M. E.

Phosphorescence, fluorescence and chemical reaction. E. C. C. BALY. *Chemistry & Industry* **47**, 914–25(1928).—B. seeks an explanation of the mechanism of chem. reaction from observations made in the allied fields of phosphorescence, fluorescence and absorption spectra. At present neither the radiation theory nor the activation-by-collision theory is adequate to account for known facts. Definite evidence is obtained in favor of the radiation theory. The radiation hypothesis states that the first stage of a chem. reaction is the activation of each mol. of the reactant by the absorption of one

quantum of energy which is called the crit. quantum of activation. Evidence gained from the exptl. investigation of the phenomena of photoluminescence gives strong support to the reality of this crit. quantum of activation but entirely disposes of the possibility of a mol. gaining this quantum by a single absorption process. It is probable that the activating quantum is greater than the actual energy of activation, the excess energy appearing as fluorescence. The connection between the observed heat of reaction and the crit. increments of activation, derived by the radiation hypothesis, is extended to photochem. quanta. The *photosynthesis* of carbohydrates from H_2CO_3 is discussed. The activation of H_2CO_3 must take place in 2 stages, namely, partial activation by absorption with the formation of a mol. state capable of absorbing some rays within the visible spectrum, whereby the activation is completed by photochem. means. The stability of the complex is affected by temp. This may be compared with the photo-activation of a phosphor, the initial complex being an absorption complex of CO_2 and $NiCO_3$. There exists a lower temp. below which the reaction will not take place; an intermediate temp zone in which the reaction will take place with a definite temp. coeff.; and an upper limit of temp. at which all reaction again ceases. Thus photosynthetic and photoluminescent processes are analogous. M. F.

Chemiluminescence between alkali metal vapors and zinc halides. M. Polanyi and G. Schay. Kaiser Wilhelm Inst., Berlin. *Z. Physik* **47**, 814-8(1928).—Vapor of Na and K at 0.01 mm. pressure were brought in contact with vapors of $SnCl_4$, $SnBr_4$ and SnI_4. A certain amt. of reduction occurred. In the app. described and with an excess of the Zn salt reduction to the dihalide takes place and there is no deposit of Zn on the walls of the app. Hence the luminescence is easy to observe. To the naked eye, $SnCl_4$ gave a blue light, $SnBr_4$ gave a green and SnI_4 a yellow color. The luminescence is intense and continuous; it is most intense at the center and falls off symmetrically at the sides. No sharp boundary is to be observed. Though it is to be expected that the continuous spectrum was due to combination of the free components P. and S. could not substantiate this. Thus, with $SnCl_4$ they could not find any HCl when H was admitted to the system. P. and S. calc. the *heat of combination* of 3 and of 4 atoms of Cl in $SnCl_4$. Since the explanation that the light is due to combination is excluded, it is assumed that the manifestation of light ensues as a result of transformation of the energy set free in the reaction. S. L. B. Etherton

The decomposition of ammonia by high-speed electrons. J. C. McLennan and Gilbert Greenwood. Univ. of Toronto. *Proc. Roy. Soc.* (London) **A120**, 283-95 (1928).—Cathode rays were obtained in the reaction chamber through a Ni window of a Coolidge cathode-ray tube. Preliminary expts. at 1 mm. of NH_3 showed that temp. effects were not present, and that it was necessary to take precautions, such as coating reaction chamber with tin foil to prevent a silent-discharge decompn. An expt. with A showed no change in pressure, indicating absence of temp. effect. With const. amperage and 1 mm. of ammonia, the decompn. was a linear function of the applied voltage. A crit. potential of 82 kv. was found below which the cathode beam did not pass through the window. With const. current of 0.2 milliamp. at 115 kv. the % decompn. decreased with rise in pressure. The initial rate of change was const. with changing initial pressure of NH_3, but increased with increasing voltage for const. pressure of NH_3. The ratio, no. of NH_3 mols. decomposing to no. of electrons causing decompn. is independent of pressure, while it increases with increase in speed of electrons. Expts. with quantities of N_2 and H_2 in initial mixt. showed that N_2 increases the amount of NH_3 decomposed, while H_2 decreases it. N_2 does not change the rate, while H_2 lowers it. The ordinary mass-action laws cannot be applied to the equil. under these exptl. conditions. Arthur Fleischer

Distribution in direction of the relative velocity of the optical dissociation products of sodium iodide. Allen C. G. Mitchell. Inst. of Physics, Göttingen. *Z. Physik* **49**, 228-35(1928).—NaI dissociates under optical excitation to form an I atom and an activated Na atom. The absorption by Na vapor of fluorescence from NaI vapor excited from Cd and Zn sparks, was measured parallel and at right angles to the exciting beam. Results showed that there was no detectable direction tendency in the velocity of the dissociating atoms, even in the presence of magnetic fields. G. M. E.

Relation between current density and cathode fall of the glow discharge with the use of a guard-ring cathode and correction for the rise in temperature of the gases. A. Güntherschulze. Physikalisch-Technische Reichsanstalt. *Z. Physik* **49**, 358-79(1928).—The cathode consisted of an Fe cylinder and guard-ring. The total diam was 11.5 cm. and the height 3.0 cm. It weighed 2.3 kg., giving a heat capacity sufficiently large to prevent appreciable warming during a series of expts. The av. raised temps. of the gases in the fall-space were calcd. and used in the Sutherland equation to calc.

the mean free path. The latter, rather than the gas pressure, is the detg. variable. The gases He, A, H_2, N_2 and O_2 were studied. They were purified (except O_2) in the discharge vessel by a glow discharge with a Na-K cathode. The cathode was freed from foreign gases by prolonged spattering. Au foil and P_2O_5 were used to remove Hg and H_2O from the O_2. The cathode fall was detd. by increasing the distance between the electrodes until the anode glow disappeared At this distance the potential between the electrodes is equal to the cathode fall. Helium is the only gas for which (const. cathode fall) $l \cdot \sqrt{i}$ = const., and d/l = const., where l is the mean free path, i is the c. d. and d is the width of the fall-space. The c. d. is the lowest for He and increases but little with cathode fall. The slopes of the c d.-cathode fall curves increase with the gases in the order He, H_2, Ne, N_2, O_2 and A. The c. d. for the latter increases rapidly with increasing cathode fall. The width of the fall-space (const. l) becomes const. in He at 300 v., but in Ne and A decreases rapidly with increasing cathode fall.
J. E. Snyder

Telescopic observation of cathode and anode points. Carl Barus. *Science* **67,** 248–9(1928).—Expts. with mucronate electrodes show that a bright and a "dark" (surface glow at the edges of the anode) type of spark follow the extinction of the cathode glow. A negatively charged body at a fixed distance extinguishes the cathode glow. The effect of the neg. body at various positions shows that the rays emitted from a mucronate anode are pos. ions.
J. E. S.

Velocity of particles sputtered by disruptive discharges. Hantaro Nagaoka and Tetsugoro Futagami. Inst. Phys. Chem. Research, Tokyo. *Proc. Imp. Acad.* (Japan) **4,** 201–4(1928).—By photographing the sputtered particles on a film rotating with a known velocity and measuring the tracks, the velocity of the particles can be found. The mean velocities (in m /sec.) found are: W 43, Mg 37, Ce 90, but as the speed depends on voltage, current strength and the form of the electrodes, these values are indicative only of its order of magnitude.
C. J. West

Condensible gas modifications formed under the influence of electrodeless discharges. James Taylor. *Nature* **122,** 347(1928).—When a liquid-air trap is maintained in a gas subjected to an electrodeless discharge in glass vessels, condensible products are formed. When H is the gas water is the condensible product. The O is derived from the glass by electrolysis. When O is the gas, the condensible product gives a spectrogram identical with that of CO_2. The C comes from the glass. At the beginning of a run in H, H_2 disappears for each electronic charge conveyed but later only H disappears for each charge. The O disappears more easily than H. In the absence of a liquid-air trap, continued discharge may disintegrate the H_2O or CO_2 previously formed. The glass walls retain the mols. formed during a clean up by such a discharge.
F. E. Brown

The problem of the normal cathode drop. R. Seeliger. *Naturwissenschaften* **16,** 665–9(1928); cf. *C. A.* **21,** 3536.—A review is given of qual. theories on the explanation of the "normal" cathode potential drop in a gaseous discharge, the maintenance of the cathode dark space, etc. Different theories are based on (1) the assumption of dynamic stabilization of ion and electron liberation before the cathode to maintain their proper concns., (2) space charge assumptions using Poisson's equation, (3) most favorable potential distribution (Compton and Dällenbach), (4) (author's theory) equil. at the discharge edge between diffusion and radial electrostatic forces. Definite conclusions have not been obtained so far.
B. J. C. van der Hoeven

Luminous beads of metal particles sputtered by disruptive discharge in magnetic field. Hantaro Nagaoka and Tetsugoro Futagami. Inst. Phys. Chem. Research. *Proc. Imp. Acad.* (Japan) **4,** 106–8(1928).—Photographs are given showing the peculiar beaded tracks of metal particles sputtered in a magnetic field. Various explanations are offered, the most probable cause being the alternate formation and loss of an oxide film on the surface of the particle.
C. J. West

Electrical discharges in gases at low pressures. Irving Langmuir. *Z. Physik* **46,** 271–99(1927).—An analysis is advanced of the motion of ions and electrons in gases at pressures such that the mean free path is of the order of 1 cm. with particular reference to discharges between a straight wire emitting electrons surrounded by a coaxial cylindrical anode. Methods of detg. the velocity distribution of the ions and electrons are described, and it has been shown that in Hg vapor the Maxwellian distribution obtains. The "electron temp." corresponding with the observed velocity distribution is not a function of the current, and it is therefore concluded that the ions and electrons are not in thermal equil. with the gas mols., the temp. of which in such discharges is but little higher than that of the walls of the contg. vessel. "Electron temps." up to 80,000°

have been observed in discharges in Hg vapor; somewhat lower values are obtained in A and in H. B. C. A.

Chemical reactions under electrodeless discharge. S. S. BHATNAGAR, RAMA KRISHNA SHAYMA AND N. G MITRA. *J. Indian Chem. Soc.* **5**, 379–82(1928).—Naphthalene was subjected to the glow discharge of a Tesla coil *in vacuo* The compd. thus obtained was purified and an analysis was made. The formula derived from cryoscopic and combustion expts. is given as $C_{24}H_{20}O$. The Tesla discharge changes: $PbSO_4$ to $PbSO_3$ and PbS, $CaSO_4$ to $CaSO_3$, $KBrO_3$ to KBrO and KBr, KIO_3 to KI and I_2, $KClO_3$ to KClO and KCl and $PbSO_4$ + Mg to PbS and MgO_2. These reactions are to be studied further. RAYMOND H. LAMBERT

The contraction of gaseous hydrogen under the influence of electric discharge. R. DELAPLACE. *Compt. rend.* **187**, 225–7(1928); cf Wendt and Landauer, *C. A.* **16**, 1343.—Purified H_2 is subjected to 50,000 v. discharge in a sealed Pyrex tube for periods up to 4 hrs, the contraction noted and the residual gas analyzed.

Time of discharge, hrs	% H_2 lost	% CO – CH_4 found	% contraction
0	0	0	0
1	4.0	1 8	2.0
2	4.6	3.2	1.0
4	4.7	4.2	1.7

The contraction is irreversible and is not due to polymerization of H_2 to H_3. G. C.

Photoelectromotive force in selenium. R. L. HANSON. Cornell Univ. *Phys Rev.* **29**, 924(1927) —A detailed study of the e. m f developed in a Se cell by illumination showed that it is not due to any thermal effect. For the same illumination the e. m. f. is independent of the current through the cell and over wide ranges it is proportional to the intensity of illumination For a given intensity of illumination the e. m. f. is a max. in the region of λ = 490. W. W STIFLER

The photoelectric current as a function of field and fatigue. A. BLANC. *Compt. rend.* **187**, 171–3(1928). – A discussion of the form of the curve representing the photoelec. current as a function of the field The frequency below which the photoelec phenomenon is produced is greater for Ag than Al. The distribution of the speed of electrons depends upon the frequency of the light if it is monochromatic and upon its compn. if it is not. Fatigue seems to be accompanied by a progressive increase in the frequency limit. E G. VANDEN BOSCHE

Studies in the experimental technic of photochemistry. VI. The energy distribution of the uviol lamp. E. BEESLEY AND H. N. RIDYARD. Univ. London. *J. Phys. Chem.* **32**, 1342-5(1928); cf. *C. A.* **22**, 3841.—The energy distribution of the uviol lamp has been examd. for the wave lengths 579, 546, 405, 365, 313 and 303 mμ, the app. of Franklin, Maddison and Reeve (*C. A.* **19**, 2300) being used. Its comparison with the quartz lamp does not recommend it as a source of light energy, but the quant information obtained may supplement early published photochem work. H. R. M

Photochemical studies. VII. The photochemical decomposition of formic acid liquid and vapor. W. N HERR AND W. ALBERT NOYES, JR. *J. Am. Chem Soc* **50**, 2345–50(1928); cf. *C. A* **22**, 2717 -- An energetical study has been made of the photochem. decompn. of HCOOH, with the unfiltered light of an Hg arc as the source of radiation. After exposure to this radiation, the HCOOH was condensed with liquid air and the decompn. products remaining in the gaseous phase were removed by a Toepler pump. In this way it was found, for the vapor, that 0.52 mol. per quantum were uncondensed by liquid air and 0.39 mol were condensed, making a total of 0.91 mol. on the av. of decompn. products per $h\nu$ absorbed The absorption band max. for the vapor was taken as 250mμ. For the liquid, with a reaction vessel fitted with quartz windows, a quantum yield of 0 46 mol. was obtained by taking 300mμ for the band max With Pyrex glass, the value was 0.14 (band max at 330mμ). The reaction mechanisms proposed assume the existence of Ramsperger and Porter's bimol. form $(HCOOH)_2$ (*C. A.* **20**, 1950). H. R. MOORE

The influence of the intensity of illumination on the velocity of the photochemical union of bromine and hydrogen, and the determination of the mean life of a postulated catalyst. FRANK BRIERS AND DAVID L. CHAPMAN. *J. Chem. Soc.* **1928**, 1802–11.—Exptl. data are presented which confirm the assertion of Bodenstein and Lütkemeyer (*C. A.* **19**, 2453), that the velocity of HBr synthesis is proportional to the square root of the intensity of light. It has been established, further, in this and other researches, that the union of H_2 and Br_2 is due to ephemeral catalysts (atoms or active mols.). The mean life of this catalyst was estd. to be 0.063 sec., a sectored disk being used to permit intermittent light of const. intensity to fall on the mixt. The periods of light

exposure then bore a const. ratio to the periods of darkness. The value obtained would be longer under less intense illumination. H. R. Moore

Photochemical reaction between bromine and tartaric acid in aqueous solution. II. Jnanendra Ghosh and Kalipada Basu. *J. Indian Chem. Soc.* **5**, 343–60(1928).—The induction period diminishes with increase in the frequency and intensity of incident light, increases as the initial concn. of tartaric acid increases, diminishes as initial concn. of Br increases and increases very considerably if HBr is added previous to exposure to light. The induction period increases as the initial p_H of soln. decreases in a mixt. of Br, tartaric acid and sodium hydrogen tartrate. The unimol. velocity const. decreases as initial concn. of Br increases, increases as concn. of tartaric acid increases, increases very considerably if part of the tartaric acid is replaced by Na H tartrate, diminishes if HBr is added before exposure to light, decreases with time, increases rapidly with increase in frequency and intensity of light and varies approx. as the square root of the light intensity. A quantum of light transforms a large no. of Br mols. into HBr. III. **The mechanism of the reaction.** *Ibid* 361–72.—The first stage of the reactions is activation of Br mols by absorption of light, the atom of Br brings about the photochem. reaction. The rate of reformation of Br_2 mol. is then $K_2[Br]^2$. Br atom reacts with O_2 as $K_3[Br]^2[O_2]$. O_2 may come from H_2O, in which it is dissolved, or from the light-dark reaction as $Br_2 + H_2O \longrightarrow 2HBr + O$. Photo-inhibitors may also be destroyed by at. Br. They may also be responsible for the photo-bromination of tartaric acid. An equation is derived which involves the const. for the first dissocn. of tartaric acid It is shown that a unimol. velocity of reaction takes place if the concn. of Na H tartrate is sufficiently great Raymond H. Lambert

Photochemical action of bromine on maleic and fumaric esters. J. Eggert, F. Wachholtz and R. Schmidt. *Z. Elektrochem* **33**, 542–5(1927); *Oesterr. Chem.-Ztg.* **30**, 110.—The effect of changes in the exptl conditions on the values of ϕ and α was studied, where ϕ is the ratio of the no. of mols. converted to the no. of quanta absorbed, and α is the ratio of Br mols. added to the no. of quanta absorbed. For the Et ester, ϕ and α are independent of variation of the ester concn. and of the radiation intensity; with the Me ester and free maleic acid, there is no dependence at high concns., but at low concns ϕ decreases with decreasing ester concn, and with increasing intensity. Both ϕ and α are markedly dependent on temp in all cases. ϕ is independent of the Br concn. and α is proportional to this concn. in all 3 cases. The effect of change of wave length of the active light (blue, 4360 A U.; green, 5470 A. U.; ultra-violet, 3650 A U.) is as follows: Et ester, $\phi_{bl}/\phi_{gr} = 1.9$; $\alpha_{bl}/\alpha_{gr} = 2$; Me ester, $\phi_{bl}/\phi_{gr} = 2.3$; $\alpha_{bl}/\alpha_{gr} = 1.9$; free maleic acid, $\phi_{uv}:\phi_{bl}:\phi_{gr} = 5:4:1$. A reaction mechanism is pictured in which the Br atoms combine with the unsatd. ester mols, E, to form relatively stable compds of the type EBr, before they are able to recombine to form mols. In the conversion of maleic into fumaric ester, the collision of Br atoms with the maleic ester mols. is supposed to favor the change from the maleinoid to the fumaroid form, until the Br atom is eventually fixed to form the radical EBr. In the additive reaction it is assumed that at the moment of collision between the Br atom and the ester mol., a Br mol. which may collide simultaneously will be taken up to form dibromosuccinic ester, with re-liberation of the Br atom. B. C. A.

Photobromination of cinnamic acid and stilbene. III. Rukmini M. Purkayastha and Jnanendra C. Ghosh. Dacca Univ *Quart. J. Indian Chem. Soc.* **4**, 553–9(1927).—Expts. in yellow light confirmed the mechanism previously deduced (*C. A.* **22**, 1151) from expts. in green and in blue light. There is an induction period in the reaction, followed by an after-effect when the source of illumination is withdrawn. If the reacting system is again exposed to light after the induction period and after-effect are over, the reaction passes through another short period of induction. From this it is concluded that a complex intermediate is formed in the process of photobromination E. H.

Photochemical ozonization and its relation to the polymerization of oxygen. Oliver R. Wulf. Univ. of Calif *J. Am. Chem. Soc.* **50**, 2596–2604(1928); *Proc. Nat. Acad. Sci* **14**, 356–8.—Warburg's classical expts. on ozonization (*C. A.* **6**, 20 and following papers) indicate that the absorption of radiation may be due to a polymer, O_4, which decomposes to give O_3 and O. Change of absorption with pressure agrees with this idea. Calcn. gives K_p = 1.2 g./cc. for the equil. const. of $2O_2 \rightleftarrows O_4$, which probably is significant only in order of magnitude. William E. Vaughan

The influence of the intensity of the incident light on the velocity of some photochemical reactions. B. K. Mukerji and N. R. Dhar. Allahabad Univ. *J. Phys. Chem.* **32**, 1308–30(1928).—A detailed study is made of velocities of 14 photochem. reactions as a function of intensity of radiation. All reactions were carried out in a ther-

mostat. A 1000-w. lamp was used as the source of radiation, and intensities were controlled by varying the size of the aperture to the reaction vessel. The velocities of the reactions fall into 3 well-defined groups; those in which velocity is proportional to the square of the intensity of radiation, those in which it is proportional to the square root of the intensity, and lastly proportional to the intensity. Reactions pre-eminently photochem. are likely to be proportional to the square root of the intensity. This occurs for the interaction of K oxalate, NH_4 oxalate, Na malate, $NaNO_2$ with I_2. The authors ascribe this to chem. changes between atoms of I_2. H. R. MOORE

Photochemical changes in hydrocarbons. I. Condensation of ethane under the action of ultra-violet rays. STANISLAW TOLLOCZKO. *Przemysl Chem.* **11**, 245–53 (1927).—The gases were submitted to ultra-violet radiation λ = 2300 – 4000 A. U. while kept in a quartz envelope surrounding a Hg lamp. CH_4 was not affected whether it was continuously exposed or was allowed to flow through the reaction chamber. C_2H_6 gave about 0.25 g. light colorless condensate which analysis showed to be composed of a mixt. of hydrocarbons, most of which was C_6H_{14}. The gaseous phase contained H_2 and CH_4. On the basis of chem. kinetics equations are derived for velocity of the reaction and for pressure within the app. at any time during the procedure. These equations are applicable to condensation of C_2H_6 to higher hydrocarbons, and are checked well by exptl. results. A. C. ZACHLIN

The photoöxidation of organic compounds by means of dichromates. I. PLOTNIKOV. *Chem.-Ztg.* 52, 669–71(1928).—Qual. expts. conducted during summer months gave the following results: $K_2Cr_2O_7$ soln. satd. with H_2 showed only slight cloudiness, the H_2 being therefore but slightly dissociated into atoms. Pure C treated similarly gave no change in 3 mos. Addn. of Mn, Co, Cu, UO_2^{II} and Fe salts as catalysts gave no results Colloidal C caused marked action, giving a voluminous ppt. CH_4 acted as did H_2, and illuminating gas caused slightly greater action. C_2H_4 and C_2H_2 reacted readily. MeOH gave a ppt. of $Cr(OH)_3$ and formed HCHO, but no HCOOH. EtOH yielded MeCHO and a brown ppt. (Cr chromate) of unknown compn. When $(NH_4)_2Cr_2O_7$ was used instead of the K salt, NH_3 and MeCHO were evolved. PrOH gave a dark brown color and a ppt., and formed EtCHO and traces of EtCOOH. iso-PrOH gave MeCOMe and AcOH with HCOOH. MeCOMe gave a brown soln. contg. AcOH, HCOOH and traces of corresponding aldehydes. $K_2Cr_2O_7$ and especially $(NH_4)_2Cr_2O_7$ dissolve in ethylene glycol, the solns. quickly become dark green and alkaline and contain glycolaldehyde and glyoxal. The green color arises from the Cr salts of glycolic, glyoxylic and oxalic acids. Glycerol reacts quickly also, giving a green soln alkaline in reaction and contg. glyceraldehyde, dihydroxyacetone and glyceric acid. C_6H_6 gave no visible change, but traces of C_6H_5OH and $(COOH)_2$ were found. The addn of $FeCl_3$ as catalyst gave a slight change, with the formation of traces of C_6H_5OH, $(COOH)_2$, glycol and a greenish yellow material of unpleasant odor. A satd. C_6H_5OH soln. treated with $K_2Cr_2O_7$ altered greatly in 10 days, giving a viscous green-brown material Quinone, pyrocatechol, hydroquinone, an oily substance and a glue-like brownish material were found. Toluene (in 4 months) yielded a soft yellow substance of pleasant odor, and tolu balsam. Tetralin similarly gave a little homophthalic acid and condensation products of unknown compn. *o*-Xylene gave *o*-toluic aldehyde and acid in small amounts. *m*-Cresol yielded *m*-toluic aldehyde and acid and an oily substance, likewise in small amounts. *p*-Cresol gave a little formic acid and xylenol Hydroquinone and $K_2Cr_2O_7$ gave a brownish red soln., evolved CO_2, and could not be filtered by any means tried. A few drops of HNO_3 caused a gelatinous ppt. to form. Quinhydrone was found; upon distn. phthalic acid was obtained, and in the residue was a brittle resin. Evidently the quinone formed at first later combined with the remaining hydroquinone. With resorcinol a viscous liquid was formed, brownish red in color, and after removal of the Cr salts a greenish fluorescent liquid remained. Phloroglucinol had been formed, together with a trace of pyrogallol. From pyrocatechol there resulted quinone in small quantities, quinonepyrocatechol and hydroxyhydroquinone. *o*-Cresol decomposed with the evolution of CO_2, the liquid sepd. into two layers, the lower, green in color, contg. $Cr(OH)_3$, unaltered cresol and a brownish red gummy mass, and the upper, colorless contg. benzoic acid and some oxalic acid. With $C_{10}H_8$ and α-$C_{10}H_7OH$ no change was noted. Cresyl blue 2BS became red and fluoresced. Nile blue behaved like it. Ethyl green, cyanine, naphthylene blue altered in the dark, but more quickly in the light. Trypan blue, indulin, dahlia, aniline green, malachite green, naphthol green, iodo green, nigrosin, Trypan red, erythrosin, indigo carmine blue, gentian violet, Guinea green B and G, brilliant safranin, aurantia, safranin, lition carmine, carmine II, rose Bengal, Rhodamin B, Hoffmann violet, methyl violet, crystal violet and cresyl (echt) violet underwent no change. $C_6H_5NH_2$ rapidly

darkened, forming aniline black and very small amts. of quinone. Mesitylene became brown and partly resinified; with Et_2O a terpene-like liquid of a yellow color was isolated and an aldehyde was detected. Pseudocumene also became brown and resinified; an aldehyde was detected, but no terpene or acid. This indicates that terpene-formation is related closely to the symmetrical structure of the mol. *p*-Aminophenol became brown, yielding much quinone and NH_3. Dihydroxyanthraquinone became brown, evolved CO_2 and formed quinone. Triphenylmethane was not changed. Isopulegol yielded only about 1% of isopulegone. Isoeugenol oxidized to a resin contg. small quantities of vanillin; probably the formation of an opaque gelatinous deposit on the walls of the vessel stopped the reaction. *n*-Octanol also caused a deposit on the walls of the container, soon stopping the reaction. Uranyl nitrate accelerated the change. An aldehyde was identified and the soln. became alk. Safrol gave an aldehyde, the walls soon became coated and the reaction stopped; uranyl nitrate accelerated the change.

W. C. Ebaugh

Influence of adsorbed ions on the absorption of light by silver bromide. K. Fajans, H. Fromherz and G. Karagunis. *Z. Elektrochem.* 33, 548–54(1927).—In explanation of the previous work of the authors (cf. *C. A.* 21, 1594), there is the possibility that long wave lengths are absorbed by a bromide body to the same extent as by a Ag body, but that the red rays are active only in the latter case because reaction with the excess of Ag salt binds the Br and prevents back reaction. To test this, the influence of adsorbed ions on the light absorption of AgBr was studied. Sols contg. about 1 millimol. of AgBr per l. were prepd., with excess of $AgNO_3$ or of KBr varying from 0 to 1 millimol. per l. The degree of coagulation of these sols became stationary after about 12 hrs.; during the next 2 hrs., which was the time necessary to carry out a measurement of absorption, it did not vary more than 1–2%. With increase of concn. of the excess salt the degree of coagulation decreases, but to a different extent for the 2 salts. The coagulation tends to a const. value with increase in the concn. of the salts, because the surface of the AgBr becomes satd with the ions. This const. value is obtained with 60% excess of $AgNO_3$ (0.6 millimol. per l.), and with 40% excess of KBr. The ratio of the degree of coagulation in the 2 cases is 1:0.35. The dispersity of a sol contg. 100% excess of $AgNO_3$ was the same as that of a sol contg. 5% excess of KBr. These 2 sols were used for the purpose of absorption measurement. AgBr-gelatin emulsions were also studied, various "bodies" being produced by bathing in solns. of the perchlorates of Ag, Tl and Na and KBr. Curves were obtained by plotting the log of wave length against the log of the extinction coeff. With aq. sols, the extinction coeff., *k*, is practically the same for both sols in the region λ 3800–4470 A. U., and the curves are approx. linear. The slope of the curves is slightly greater than that deduced from Rayleigh's formula. For the AgBr-gelatin plates, plotting log of wave length against log of extinction (*i. e.*, log *kcd*), the curves are again straight lines in the spectral region λ 3800–4700 A. U., both for the pure AgBr and for plates bathed in Ag or Na perchlorate, and KBr. The curve for pure AgBr lies slightly above those of the other 3, which practically coincide, and remain nearly straight lines into regions of long wave length. The slope is again slightly higher than that demanded by Rayleigh's formula. This shows that in this case, and also in the case of the aq. sol, scattering is largely responsible for the extinction. There is a large difference between the extinction of the Ag body and that of the bromide body and the pure AgBr which is not due to coagulation by the salts in which the plates were bathed. The extinction of the Ag body, even in the near ultra-violet, is greater than that of the bromide body; *i. e.*, the absorption of the AgBr is influenced by adsorbed ions. The difference between the extinctions of the Ag body and the bromide body increases on passing from the ultra-violet to the yellow, with both plates and sols. This indicates an extension of the light absorption into the longer wave lengths by the absorbed Ag ions. It is assumed that the size of the absorbed light quantum depends only on the absorption of energy in the first phase of the process of transfer of an electron from a bromide to a Ag ion, *i. e.*, the sepn. of an electron from a bromide ion. It will therefore depend on the condition of the bromide ions in the AgBr space-lattice. It is so markedly different in the case of NaBr from that of AgBr, because of the deforming action of the Ag ions on the bromide ions in the surface of AgBr. The shift of absorption due to adsorbed Ag ions is due to their distorting effect on the neighboring bromide ions in the AgBr lattice.

B. C. A.

Protected silver hydrosols. VI. Formation of sols by irradiation. J. Voigt. *Kolloid Z.* 45, 319–22(1928); cf. *C. A.* 22, 10.—Irradiation of dil. $AgNO_3$ or Ag_2O solns. free from reduction centers does not produce reduction. Pure gum arabic, in 0.7% soln. or more dil., previously irradiated or not, does not reduce the Ag soln. Irradiation

of a mixt. of the 2 solns. produces reduction and total pptn. with visible light, and only the formation of a sol with ultra-violet light. The ultramicroscopic particles of gum act as reduction centers. The ultra-violet radiations thus show a peptizing or charging effect, which is more evident in its dissolving power on the ppt. It is also possible to prepare Ag solns. by means of ultra-violet light in the presence of radiation centers which themselves do not act as protective colloids. G. CALINGAERT

The formation of a polymeride of carbon monosulfide by ultra-violet irradiation of carbon disulfide. Absorption spectrum of carbon disulfide in carbon tetrachloride. W. DORAN AND A. E. GILLAM. *J. Soc. Chem. Ind.* **47,** 259-60T(1928).—The red-brown solid obtained by the action of a Vita glass-screened Hg-vapor lamp on mixt. of CS_2 and CCl_4 is examd. and found to be a polymeride of CS. The absorption spectrum of CS_2 in CCl_4 is discussed. The portion of the curve due to CCl_4 is below the wave length transmitted by Vita glass (275$\mu\mu$) and thus CCl_4 can safely be used as a solvent in photochem. reaction occurring with rays on the long wave length side of 275$\mu\mu$. M. F.

Phototropic compounds of mercury. S. V. RAGHAVA RAO AND H. E. WATSON. Indian Inst. of Science. *J. Phys. Chem.* **32,** 1354-65(1928).—An exhaustive study has been made of the photographic characteristics of 20 Hg compds. of the type $X{\cdot}HgCNY$, HgX_2 and $2HgY$ (X = Cl, Br, I, HS, HSe, CNS, CNSe; Y = O, S, Se). These yellow or brown compds. become black by exposure to sunlight and regain their original color by standing 1-3 days in the dark or by heating. A spectroscopic examn. was carried out for 10 of the more sensitive ones. A 100-c. p. pointolite lamp was used as the source of radiation in the visible and an Fe arc for the ultra-violet. The threshold wave length for darkening was 5500 A. U. and less; the sensitivity max., however, were shifted towards the green by dyes such as erythrosin, methyl green, eosin and methylene blue. Reversal was promoted by red light, also by heat. The temp. coeffs. of direct and reverse reaction velocities were 1.9, the av. value for chem. changes of the ordinary type. The effects produced were directly proportional to light intensity. H. R. M.

Excited systems formed by the absorption of light. LOUIS A. TURNER. *J. Phys. Chem.* **32,** 507-15(1928).—Primary absorption may cause displaced electron orbits (Bohr theory), ions (by photoelec. effect) or such mol. modifications as have energy content higher than the original system. Many chem. changes may result from these excited systems independent of the absorption mechanism. HARRY B. WEISER

Absorption coefficients. HENRY G. DE LASZLO. *J. Phys. Chem.* **32,** 503-6(1928).—The measurement of absorption coeffs has been made chiefly on pure liquids and to a certain extent recently on vapors and gases. Two general methods are employed: (1) photographic methods and (2) photoelec. cell and microphotometric methods. The principles underlying each are discussed. HARRY B. WEISER

Relation between photochemical and ionization reactions. S. C. LIND. *J. Phys. Chem.* **32,** 573-5(1928).—A review of observations on a few photochem. and ionization reactions leads to the conclusion that there is great need for the examn. of more reactions by methods of activation, ionization and excitation under identical conditions in order to establish the relationship between the quantum yield $M/h\nu$ of the photochem. reaction and the M/N yield of the ionic reaction. HARRY B. WEISER

Photochemical clustering. B. LEWIS. *Nature* **121,** 792(1928).—Macdonald's views of the mechanism of the photochem. decompn. of N_2O (*C. A.* **22,** 2112 and private communication) are discussed; the agreement between the value for $M/h\nu$ and that for M/N in the α-ray reaction (Lind, preceding abstr.) suggests clustering, but a general theory of photochem. clustering is not proposed. The view is, however, more acceptable for reactions involving assocn. or polymerization. B. C. A.

Experimental technic for quantitative study of photochemical reactions. GEORGE SHANNON FORBES. *J. Phys. Chem.* **32,** 482-502(1928).—A selective and crit. survey of the technic for the study of chem. reactions evolved by light from external sources from the red to the beginning of the Schumann region. Sections are devoted to general sources of information; sources of light (a) with approx. continuous spectra, and (b) with discontinuous spectra; and quant. measurement of radiation intensity. HARRY B. WEISER

Displacement of equilibrium by light. WILDER D. BANCROFT. *J. Phys. Chem.* **32,** 529-72(1928).—A no. of photochem. processes are reviewed in detail on the theory of the displacement of equil. by light. It is concluded that this theory offers the simplest interpretation of the facts when confined to reversible equil. The conditions must be such that a photochem. change takes place and that the rate of this change shall be greater than the sum of the rates of the reverse reaction in the dark and in the light. The amt. of the displacement of equil. by any given light usually decreases with rising temp., since raising the temp. usually increases considerably the rate of the re-

verse reaction in the dark relatively to the rates of the photochem. reactions.

HARRY B. WEISER

Quantum processes in photochemistry. HUGH S. TAYLOR. *J. Phys. Chem.* **32**, 516–27(1928).—Photochem. processes are discussed in the light of the quantum theory with especial reference to depolarizers, inhibition and such processes as the hydrogen-halogen reaction, the oxidation of quinine and the reduction of Fehling solution. The attempt to couple the concept of quantized absorption with the net photochem. yield has not been successful. Indeed, in the case of some workers this suggestion of equivalence has given rise to mistrust of the general idea of quantized absorption which is basic to all modern studies of photochem. processes and is demanded by phys. theory. The situation may be met by the two laws of photochemistry, the first that of Grotthuss and Draper, the second: "That the absorption of light is a quantum process involving one quantum per absorbing mol., the photochem. yield being detd. by the thermal reactions of the system produced by the light absorption." HARRY B. WEISER

4—ELECTROCHEMISTRY

COLIN G. FINK

Oxidation reactions in the luminous arc electric furnace. K. V. KERPELY. *Zentr. Hutten Walzwerke* **31**, 471–5; *Chem Zentr.* **1927**, II, 2005.—A review of oxidation reactions during the production of steel in the arc furnace, their influence and effects on the metal and slag. C. C. DAVIS

Industrial electric heating. The single-phase arc furnace. N. R. STANSEL. *Gen Elec. Rev.* **31**, 483(1928).—A review of the Detroit and Booth furnaces and operation. C. G. F.

Making electric manganese steel. J. H. HRUSKA. *Iron Age* **122**, 455–6(1928).—The generally accepted specifications for austenitic Mn steels is as follows: less than 1 1% C; 11.5–13.5% Mn; less than 0.6% Si; less than 0.065 P; less than 0.020% S. A complete outline of a heat made in a 7-ton basic Heroult furnace, including nature of charge, heating cycle, slagging, addns., analyses of steel and slag is presented. A heat balance, based on H.'s previous article (*C. A.* **20**, 1564), is as follows: Steel 48.8%, slags 8.2%, cooling rings 2.9%, transformer 1.3%, radiation, etc., 38.8%. Bottom pouring is generally practiced so that quicker teeming and the production of sounder metal is possible. A. D. SPILLMAN

The charge of the electric furnace. K. VON KERPELY. *Giesserei* **15**, 225–9(1928).—A brief discussion of the influence of the size and shape of steel scrap on the charging and current consumption of the elec. furnace. The advantages and disadvantages

of acid- and basic-lined elec. furnaces are discussed. The prepn. of various types of steel is discussed. J. Balozian

Electric furnaces for melting metals and alloys. Karl Kalman. *Zentr. Hütten- u. Walzwerke* **31,** 347–51; *Chem. Zentr.* **1927,** II, 1074.—A review of the advantages of elec. furnaces in the industries with particular reference to high-frequency furnaces. J. S. Reichert

The energy losses in the electric arc steel furnace. St. Kris. *Arch. Eisenhüttenwesen* **1,** 413–9(1927).—The distribution of the energy losses in an elec. steel furnace is detd. partly from investigations on a plant scale, and partly from the results of Keil and Hess (*Stahl u. Eisen* **45,** 1134–46(1925)) and Lyche and Neuhauss (*Ber. Stahlw.-Aussch. V. Eisenh.* No. 101(1926)). They are divided into: (1) elec losses (transformer, cable, electrode); (2) losses due to the conduction and radiation of heat; (3) losses due to escaping gases. The transformer losses, consisting of Fe (hysteresis and eddy current) and Cu (ohmic resistance of the windings), are for a 5-ton furnace equal to 3.3% of the total input. Those losses in the line from the transformer to the furnace, consisting of Cu, inductive and electrode (outside the furnace) losses, are 6% The energy lost in heating the cooling H_2O is 4.1%. The losses due to the conduction and radiation from the furnace, calcd. from measurements of temps. at various points on its exterior walls, are 15.2%. The heat lost through opening of, or cracks in, the doors, etc., increases as the 4th power of the temp. of the radiating surface, and amounts to 6.6% of the total energy input. The loss of energy in the gases developed during refining and deoxidation, and by the formation of CaC_2 and the consumption of the electrodes due to air sucked in through electrode openings, is 4.3%. The total calcd. energy input, using the above figures and allowing for the energy consumed during the melting, is in agreement with actual furnace performance. J. Balozian

Large capacity vacuum electric resistance furnace for the preparation of experimental alloys. Pure magnesia crucibles for very high temperatures. G. Chaudron and M. Garvin. École nationale supérieure des mines. *Chimie et industrie* Special No., 386–7(April, 1928); cf. *C. A.* **17,** 2374; **21,** 514.—An illustrated description is given of a furnace of larger capacity, in which can be melted 400–500 g. Fe, or 400 g. Pt using only half the capacity of the crucible. In order to obtain malleable Pt the MgO crucible must be lined with a very thin coating of CaO; fusion is obtained in 15 min. with a power input of about 10 kw. Crucibles of pure MgO withstand the highest temps. of this furnace (2600°) and are not very sensitive to sudden changes of temp. Even when full of molten Pt they can be withdrawn directly from the furnace into the atm.; but they do not stand the oxy-H blowpipe because it does not heat them uniformly. A. Papineau-Couture

A valve-maintained high-frequency induction furnace and some notes on the performance of induction furnaces. A. Eric Bell. *Proc. Phys. Soc. London* **40,** 193–205(1928).—The elec. design of a valve-operated, high-frequency furnace capable of meeting the varied demands of a research lab. is described. The frequency and other consts. can be varied over a wide range. A 12–15-kv.-a. unit for this purpose is described in detail, together with its operation and performance. Exptl. results on the performance of high frequency furnaces including energy supplied as heat to the charge and that lost by heating the inductor are presented. A. D. Spillman

An electric crucible furnace with air circulation. G. H. Abels and E. M. Titov. *Ann. inst. polytech. Oural* **6,** 351–3(1927).—An elec. furnace for ignition and fusing is described. The furnace is built in the shape of a vertical cylinder 5 × 5 cm., has a double cover and bottom in which channels for circulation of air are arranged. The channel in the bottom is adjustable for the regulation of the air stream. G. B. K.

The development of the electrode industry. Gustav Schuchardt. *Zentr. Hütten- u. Walzwerke* **31,** 597–9; *Chem. Zentr.* **1927,** II, 2775.—A review of progress in the production of *carbon steel* and *Al* electrodes. C. C. Davis

High-efficiency motor-generator sets for electrolyzing leaching-plant solution. David Hall. Am. Inst. Min. Metall. Eng., *Techn. Publ.* No. **132** (Sept., 1928).—The installation of the Inspiration Copper Co., Arizona, is briefly described. Motor generators are used. At full loads the losses are less than 8%. The av. current and voltage requirements during 1927 were approx. 32,000 amp. at 300 v., supplying current to 120 electrolytic cells, each contg. 85 Pb anodes and 84 cathodes, and 14 cells in which the Cu starting sheets were made. C. G. F.

Studies in electroplating. Electrodeposition on aluminum. III. The non-adhesion of electrodeposits. W. E. Hughes. *Metal Ind.* (London) **33,** 173–6(1928).—A historical discussion of non-adhesion covers minutely its causes, which are enumerated and classified. Numerous references are made to the literature. W. H. Boynton

Health hazards in chromium plating. J. J. Bloomfield and William Blum. U. S. Pub. Health Service. *Pub. Health Repts.* **43**, 2330–51(1928).—Air analyses and medical examns. indicate that continuous daily exposure to a concn. of CrO_3 greater than 1 mg. in 10 cu. m. is likely to cause definite injury to the nasal tissues of the operators. The most efficient method of ventilation is to draw the air laterally across the top of the plating tanks into ducts 1 to 2 inches wide and extending fully along one or more sides of the tank. Tanks wider than 18 inches should have ducts on both sides, or else two ducts in the center, the air velocity at the duct being about 2000 ft. per min. The level of the plating soln. should be at least 8 inches below the top of the tank and the duct should be at the top of the tank. Injury by the CrO_3 solns. and mist can be decreased by frequent washing in dil. Na. thiosulfate, or bisulfite, or NH_4 polysulfide; and by application of vaseline, lanolin or mentholatum salve. C. M. Salls

Electrodeposition of metallic alloys from aqueous solutions of binary electrolytes. I. Copper-cadmium alloy. N. N. Efremov. *Ann. inst. polytechn. Oural* **6**, 111–50 (1927).—E. has investigated the effect of varying conditions, such as the compn. of the electrolytic bath and of the anode and cathode materials, the c. d. and the temp. on the electrodeposition of Cu-Cd alloys. Expts. show that only with complex salts such as cyanides a simultaneous deposit of both metals obtains. The electrode potential of Cu was found to be higher than that of Cd in solns. of cyanides except when the concn. of KCN was kept below 0.3 *N*. Correspondingly only from these latter soln. can an alloy be obtained, deposits of Cd only resulting otherwise. This is due to the fact that Cd does not have a depolarizing action on the cathode as does Cu in Cu-Zn soln. The ratio Cu: Cd in soln. is the main factor affecting the compn. of the alloy. However, the product obtained under seemingly identical conditions varies considerably in compn. Thus, with the 1:1 wt. ratio of Cd:Cu, alloys contg. from 64 to 72% Cd were obtained. The compn. of the anode does not influence the deposition materially and the Cu-Cd anodes dissolve only slowly in the cyanide soln. studied. Temp has little influence on the compn. of the product. The current efficiency is also almost independent from temp. (17–60°) but is influenced by the c. d. While higher c. d. promotes efficiency, the most advantageous current is 40–60 amp. per sq. m. since it yields the best deposits combining them with high efficiency (88–90%). The Cu-Cd alloys obtained form well-adhering deposits on Pt, Cu, Cd, Fe, Pb, Al, Au and other metals. E. points out furthermore that according to his observations such exothermic compds. as Cd_3Cu_2 and $CdCu_3$, when present in the anode, are very easily decompd. by the electrolysis. G. B. K.

The influence of p_H in the electrolytic deposition of copper in the presence of gelatin. C. Marie and M. L. Claudel. *Compt. rend.* **187**, 170–1(1928).—When depositing Cu from a soln. of $CuSO_4$ contg. gelatin, the max. surcharge is obtained at p_H 3.5 and the min. is obtained at the isoelec. point, p_H 4.7. E. G. Vanden Bosche

A new rapid galvanizing process and the present galvanization in static, acid electrolytes. H. Paweck and J. Seihser. *Zentr. Hütten- u. Walzwerke* **31**, 305–10, 322–5; *Chem. Zentr.* **1927**, II, 737.—An extensive study was made in an attempt to shorten the time required by the galvanizing process. A more rapid process was based on the use of a circulating electrolyte in which a Zn coating of 100 g./sq. m. can be put on with 5–6 v., 5000 amps./sq. m., and an 80% current efficiency in $1^1/_2$ min. The baths consisted of $ZnSO_4$ or $ZnCl_2$ solns. (8–12%), to part of which H_3BO_3 was added. J. S. Reichert

Application of electrolytic zinc process to Tri-States ores. H. R. Hanley. *Bull. Am. Zinc Inst.* **11**, 136–44(1928).—Advancement in the electrolytic Zn industry runs parallel with the improvements made in selective flotation. The demand of high-grade concentrate by the electrolytic plant is due to the resultant lower Fe, and to the lower wt. of leached residue. The factors associated with the continuity of flow of materials through the plant are: purification of soln, the maintenance of this purity, and coördinated organization. Characteristics of Tri-States' (Joplin) concentrates may be summarized as: (1) Zn in the calcine is 97–8% sol. in dil. H_2SO_4; (2) only a trace of Fe is present, necessitating addns if As or Sb develop by repeated cycles; (3) the settling of the neutral pulp and the filtration of the acid mud are reasonably satisfactory; (4) the complete sepn. of Cd is a matter of standard practice; and (5) Co can be economically taken care of if it reaches unexpected proportions. A general plant procedure is outlined. W. H. Boynton

Cadmium as a by-product of the zinc industry. M. Altmayer. *J. four élec.* **37**, 237–8(1928).—If the Cu-Cd-Zn ppt. is As-free the steps in the process are as follows: (1) leaching with dil. H_2SO_4; (2) separation of the high-Cu residue from the soln. contg. the Cd and Zn; (3) pptn. of sponge Cd; (4) dissolving the Cd sponge in hot dil. H_2SO_4

(electrolyte); (5) elimination of Fe; (6) elimination of Tl; (7) cathodic deposition of Cd. For step (1) H_2SO_4 soln. contains 250 g./l. at 60°. The excess acid is neutralized with lime and black Cu oxide is pptd. C. G. F.

The manufacture of aluminum. H. BACH. *Zentr. Hutten- u. Walzwerke* **31**, 289–93, 354–7; *Chem. Zentr.* **1927**, II, 1075.—The new plants of the Aluminum Co. of Canada at Aroida are described. J. S. REICHERT

Cryolite. ANON. *Mineral Ind.* **36**, 202(1927).—Statistics of production and trade are given. A B.

The electrolytic preparation of cuprous oxide. E. ABEL AND O. REDLICH. *Z. Elektrochem.* **34**, 323–6(1928).—A study of the effect of electrolyte, electrode material, c. d. and temp. on the efficiency of production of Cu_2O and the nature of the product obtained. The relative speeds of the various possible ionic reactions, and the reversible e. m. fs. corresponding to them are discussed. The best condition for the electrolytic production of Cu_2O are found to be: slightly alk. soln. of NaCl (110 g. NaCl and 1.2 g. NaOH per l.) as electrolyte; electrodes of electrolytic Cu so arranged that the oxide which scales off will not remain in contact with the electrodes; a c. d. of 0.5 to 1.0 amp./sq. dm. and reversal of current every 45 min. W. J. SWEENEY

Direct electrolytic preparation of potassium permanganate. GASTON RAPIN. *Compt. rend.* **187**, 112–4(1928).—The direct electrolytic prepn. of $KMnO_4$ consists of electrolyzing an aq. soln. of KOH or other K salt with a manganese-alloy anode. A relatively pure product is made in a one-step process, requiring little labor, and avoiding corrosion of the reaction vessel. Disadvantages are low current efficiency, high energy consumption and rapid covering of the generally used ferro-manganese anode by an adherent insulating coat of Fe and Mn oxides. Powdered ferro-Mn anodes will not yield $KMnO_4$ probably because of catalytic effects. R. improves the process by using cast silico-manganese (Si 33%, Mn 66%), which corrodes uniformly. With KOH both $KMnO_4$ and K_2MnO_4 are formed. The concn. of the latter becomes const. $KMnO_4$ crystals, mixed with pulverulent unattacked silico Mn and Fe and Mn oxides, collect on the bottom of the cell. Si remains in soln. as K_2SiO_3. With K_2CO_3 only $KMnO_4$ is formed, and Si is pptd. as SiO_2. Other conditions being the same, higher yields are obtained with KOH. High temp. (60°) gives higher $KMnO_4$ yield, better current and energy efficiencies, and faster anodic corrosion. KOH concn. should be about 6*N*; higher concn. results in increased voltage and slower corrosion. 50° Bé. soln. yields only K_2MnO_4. B. MILLER

Carbonates in silver (cyanide) solution. GEORGE B. HOGABOOM. *Metal Ind.* (London) **32**, 401–2(1928).—Exptl. work on the effect of K_2CO_3 in Ag plating solns. confirm the opinion of American platers that carbonates are detrimental. Both anode and cathode efficiencies are affected, thereby affecting their polarization, anode corrosion, soln. maintenance, cathode structure and applied voltage. It is doubtful whether the improved cond. afforded by high carbonates is sufficient justification for their use in concn. materially affecting the above-mentioned factors. W. H. BOYNTON

The electrolytic oxidation of aniline. JAROMIL SLÁDEK. Charles Univ., Prague. *Časopis Československého Lékárnictva* **7**, 299–312(1927).—The best conditions for the formation of quinone by the electrolytic oxidation of aniline are (1) the use of V_2O_5, which is the best catalyst, (2) continuous oxidation, (3) a high anodic surface relative to the quantity of anolyte, (4) a current density of 1 amp./sq. dm. (5) a temp. below 10°. WILLIAM J. HUSA

Cathodo-luminescence and the luminescence of incandescent solids. E. L. NICHOLS, H. L. HOWES AND D. T. WILBER. *Carnegie Inst. Washington Pub.* **384**, viii + 350 pp.(1928).—"It has been the purpose of this treatise, and particularly of this final chapter, to bring together the accumulating evidence connecting the luminescence of incandescent bodies with the fluorescence of solids at ordinary temps. We think, in view of the facts here presented, that the luminescence superimposed upon the incandescence of the various solids is simply a *fluorescence* in all essentials identical with that commonly excited by light, cathode rays, and other familiar agencies." JOSEPH S. HEPBURN

Overpotential at metallic cathodes. Cadmium and antimony in neutral and alkaline solutions. JULIUS GRANT. Sir John Cass Technical Institute. *Trans. Faraday Soc.* **24**, 367–70(1928); cf. *C. A.* **22**, 1105.—The results for these metals are in agreement with those for Ag. An attempt is made to explain the deviations from the linear *p*H-overvoltage relation. B. MILLER

Studies on overvoltage. IV. The measurement of minimum overvoltage from the current-voltage curves. TADASHI ONODA. *Z. anorg. allgem. Chem.* **172**, 87–108 (1928).—The H overvoltage on Au, Pt, Cu, Ni and Hg are detd. from the current-volt-

age curves. As in the bubble method, the overvoltage changes with the surface condition and previous treatment of the metal. The min. overvoltage, as detd. by the current-voltage method, shows approx. agreement with that detd. by the bubble method. Mean values for min. H overvoltage in $2N$ H_2SO_4 at 30° are: Pt 0.00061, Au 0.0084, Ni 0.084, Cu 0.091 v. **V. The relation between minimum overvoltage and current density.** *Ibid* 109–20.—Detns. were made on the O overvoltage of Au electrodes with change in the c. d. A min. overvoltage dependent on the quantity of electricity used for the anodic polarization appeared. The relation between min. overvoltage and c. d. is well represented by the equation $E_m = E_0I^b$, where b is a const. dependent on the metal of the electrode, and I equals the c. d. in milliamps. per sq. cm. Expts. were carried out which tend to prove that the overvoltage is not affected by an oxide film.

W. J. Sweeney

Modifications of the Sand auxiliary electrode. Thomas B. Smith. *Trans. Faraday Soc.* **24,** 216–25(1928).—"The value of the Sand electrode is generally recognized for accurately controlling the potential drop at the cathode during sepns. of metals, the O_2 potentials of which are very close to one another or to that of H_2." Several modifications are described and illus. Expts. indicate that with the aid of connecting liquids of high conductance, the resistance of the auxiliary electrode circuit can be reduced sufficiently to permit the use of an instrument of moderate sensitivity, provided that the potential of the auxiliary cell remains const. under the working conditions. Substitution of a porous diaphragm instead of the special tap of the Sand electrode, and a modification of the design of the tube result in reduction of the working resistance of the auxiliary electrode to about $^1/_{10}$ of the usual, enabling the potentiometer voltmeter to function also as a null-point detector without causing appreciable error on account of concn. polarization of the half-cells. This type may be used for some time without refilling with electrolyte. The employment of a voltmeter for detection of the null point is more convenient and more economical than the use of a capillary electrometer. The modification using connecting liquids of higher cond. than usual is conveniently employed as a quinhydrone electrode in the control of Bi estns. • Arrangements are described for utilizing, and where necessary, modifying panel-mounting radio app. so as to permit of the enclosure of the parts most vulnerable to attack by acid fumes.

W. H. Boynton

High-voltage (lead) storage battery. L. E. Dickinson. *Bell Labs. Record* **5,** 163–5(1928).—The storage battery furnishes the best source of d. c. of several hundred amps. at high potential for the development of fuses, protector blocks and other pieces of protective app. for telephone use. The battery described has 2112 cells, each of 60 amp-hrs. capacity, permanently connected together into groups of 44, which may be connected together as wanted. The cell groups are mounted in series or in parallel by knife switches. Any voltage between 90 and 4320 can be obtained in steps of 90 v. Other switch panels provide for battery connection to start and stop testing, and for charging. Four illustrations are given.

W. H. Boynton

Instruction on the making of potassium hydride photoelectric cells. Wayne B. Nottingham. Bartol Foundation. *J. Franklin Institute* **205,** 637–48(1928).—Detailed instructions for prepg. this type of cell are given. The mech. construction, prepn. of the K metal, purification of the A, production of the H_2, baking out and distn., circuits for measuring the photoelec. current, formation of the hydride, and detn. of the crit. voltage are discussed.

W. T. Richards

The lead acid cell. Harold G. Brown. *J. Royal Soc. Arts* No. **3939,** 675–710 (1928).—This discussion of the Pb acid cell and its place in modern industry is very comprehensive and is divided into 3 parts. (1) deals with historical development and the tech. and theoretical aspects of the cell since its inception by Planté in 1859. Features of both Planté and Faure types Pb cells are included. Comparative weights are: for Planté 3.1–3.75 w.-hr. per lb. of cell; for Faure 9–10–12 w.-hr. per lb. of cell. (2) is devoted to the use of a Pb acid cell as a power unit in central stations. During peak loads the batteries discharge while during the valleys of station loads the batteries are charged. (3) deals with modern developments and the use of Pb acid cells in telephone exchanges, railway work for automatic signaling, submarines and for traction. Comparative figures for Pb storage batteries and Fe-Ni (Edison-Jungner) batteries are given which will assist in selecting the most suitable type for a given kind of duty. It is concluded that the Pb acid cell will be the principal means of storing elec. energy for years to come.

How electricity produces commercially pure acids. C. M. Hoff. *Chem. Met. Eng.* **35,** 419–20 (1928).—See *C. A.* **22,** 1732.

C. J. Brockman

Characteristics of photoelectric tubes (cesium). L. R. Koller and H. A. Breed-

ING. *Gen. Elec. Rev.* 31, 476(1928).—The most useful property of the photoelec. tube is the definite relation that exists between the intensity of light falling upon the tube and the amount of current that a const. voltage will force through the tube. For special types of construction and operation the relation is linear. The tubes described are spherical glass bulbs with silvered inside surface upon which a monatomic film of Cs is deposited, the Cs and Ag serving as cathode. The anode is a pair of wires projecting into the bulb to its center. Two of the tubes were 2.5 in. in diam. with a 1.5-in. window. The anode leads carried at their tip a Ni disk $^1/_8$ in. in diam. Both high vacuum and A-filled (0.02 to 0.04 mm. Hg pressure) tubes were investigated. The tubes were photometered and numerous charts are given. The photoelec. current is almost directly proportional to the illumination intensity in foot-candles. Upon increasing the A pressure in the tube (at a fixed voltage) from zero upwards the sensitivity increases rapidly, reaches a sharp max. (at about 0.2 mm. Hg) and then drops off rapidly again until at about 0.5 mm. the sensitivity begins to drop off gradually. With varying voltage the max. sensitivity is obtained at about 0.075 mm. A. The pressure giving the highest sensitivity is not always the most desirable on account of the instability of the tube. C. G. F.

Metallic precipitates under the microscope. M. ZWÖLFMEYER. *Blätter Unters. Forsch. Instr.* 1, 53-6; *Chem. Zentr.* 1927, II, 2709.—By means of pictures of polished surfaces investigations of materials used heretofore as anodes in nickel baths, *i. e.*, cast, rolled and elec. pptd. anodes, and ppts. on various metals in galvanic baths, are described and illustrated and the importance of such investigations in relation to these industrial applications is discussed. C. C. DAVIS

(Cottrell) precipitation in Europe. G. BERG. *Elec. World* 92, 499-503(1928); 8 illus.—A review. There are about 2000 plants now in operation. C. G. F.

Cottrell electrostatic dust recovery apparatus at the "Krasni Vyborgets" plant. A. A. BAIMAKOV AND A. A. BOULAK. *Rev. soc. russe métal.* No. 1, 165-76 (1927); *Rev. métal.* 25(Extraits), 348(1928).—A description of the installation. In cold weather the gases are sufficiently moist to effect recovery of the ZnO dust produced in the recovery of Cu from brass; but in warm weather steam is injected into the app. A. PAPINEAU-COUTURE

Thin-film rectifiers. J. SLEPIAN. *Trans. Am. Electrochem. Soc.* 54 (preprint), 30 pp., 19 illus.—An exhaustive review of the principle underlying the operation of thermionic rectifiers and application to a theory of thin-film rectifiers. This theory is applied to other types of rectifiers including crystal detectors, Ta and ferro-Si rectifiers, electrolytic rectifiers with metallic conduction, the Cu hemi-sulfide rectifier of Pawlowski, and the Cu oxide rectifier of Gorndahl. In all cases it is assumed that a thin film is insulating in itself due to lack of free electrons or ions, rather than to any enormous opposition to the motion of electrons or ions. If a sufficiently high voltage is applied the electrons emitted from the cathode may cause elec. breakdown of the film, that is, the development in it of free electrode or ions. C. G. F.

Results obtained with aluminum transmission lines. H. SCHMITT. *Z. Metallkunde* 20, 305-8(1928).—A discussion of the replies to a questionnaire regarding the success obtained with Al and steel-Al elec. transmission lines in Germany. A diminishingly small no. of Al conductors had to be replaced, and principally because of insufficient purity of the metal. Where the purity of the Al used is above 99%, good results have usually been obtained. In general the highest stress allowed is 8 kg./sq. mm. Neither proximity to factories and mines nor the occurrence of frost and ice harms otherwise satisfactory Al conductors. Only 2 companies gave a generally unfavorable opinion. Eighteen companies, representing about 50% of the total wire length covered by the questionnaire, reported merely on the magnitude and type of any defects encountered, without giving any general opinion. Ten companies, representing 40% of the total wire length, either gave an unqualified favorable opinion or failed to indicate any defects. H. STOERTZ

Residual thermoelectricity of a mercury filament. TOSHIMASA TSUTSUI. *Proc. Imp. Acad. Tokyo* 4, 279-82(1928).—The effects of the geometrical cross-section and of the thin surface layer of a filament on its residual thermoelectricity were studied. The Hg was placed in a long capillary tube of which a portion was heated. The thermoelectric effect was measured for different sections heated. A constriction in the tube caused the Hg within it to behave quite differently from that in the main capillary, a distinct e. m. f. being noticed at the junction. The contact between the glass and Hg appears to have an important but undetd. influence. The conclusions are: The observed e. m. f. is not due to internal structure as in metallic wires; geometrical form of the cross-section is without effect in the case of Hg, within the accuracy of these expts.;

Hg contained in a small tube inserted in a larger tube behaves like a different material toward Hg in the larger tube; the seat of the e. m. f. is unstable. The smaller the diam. the greater the instability. R. L. HERSHEY

Central-station use of pulverized coal (TENNEY) 21. Electrolysis of sugar juices (BERGE) 28. The electric micro-combustion furnace of Heraeus (FLASCHENTRÄGER) 1. Electric batteries (suitable for use with flash lamps). C. GAISER. Brit. 284,626, Feb. 1, 1927. Structural features.

Dry-cell electric battery. HOWARD D. HODGE (to Burgess Battery Co.). U. S. 1,684,735, Sept. 18. Structural features.

Electric battery of the Leclanche type. GEORGE N. ANTONOFF (to Matthew A. Adam). U. S. 1,687,051, Oct. 9. A cell with an outer moisture-retaining case which may be formed of paraffined cardboard provides free ventilation for the Zn electrode both externally and internally and has a firm gelatinous electrolyte which may be formed from tapioca and NH_4Cl.

Galvanic cell. M. M. POPOV-PLATONOV. Russ. 3754, Oct. 31, 1927. A Zn-C cell is characterized by a depolarizer pressed from wood charcoal previously satd. with O_2 or O_3 with or without the addition of $CaOCl_2$.

Prevention of corrosion on galvanic cell terminals. B. V. SIZAREV. Russ. 3780, Oct 31, 1927. The electrolyte is covered by a mixture of 85% oil drier, 10% drying oil and 5% petrolatum.

Storage battery. M. ESPAGNENT. Brit. 285,501, Feb. 18, 1927. Structural features.

Storage battery. CHARLES J. V. FÉRY. U. S. 1,685,695, Sept. 25. See Brit. 275,750 (*C. A.* **22,** 2330).

Storage batteries. CHARLES J. V. FÉRY. Fr. 32,646, Apr. 26, 1926. Addn. to 611,129. A layer of heavy oil above the electrolyte protects the negative plates from oxidation.

Storage battery. OLDHAM & SON, LTD. AND H. E. CLARKE. Brit. 284,953, Nov. 3, 1926. Structural features.

Storage battery. D. P. BATTERY CO., LTD., J. WADDELL and B. M. DRAKE. Brit 285,226, Jan. 18, 1927 Separators of glass wool felt are used together with other separators which may be formed of wood, ebonite or perforated celluloid.

Storage battery. I. G. FARBENIND. A.-G. Brit. 284,352, Jan. 28, 1927. Pb grids of storage battery plates are provided with openings which are filled with an alloy of Pb and Na. Structural features and a method of making the plates are specified.

Storage battery. I. G. FARBENIND. A.-G. Brit. 285,354, Feb. 12, 1927. Pb skeleton grids are coated with a protective coating such as an oxide, sulfide or sulfate of Pb (suitably by dipping the skeleton, with or without previous oxidation, into H_2SO_4 or a sulfide soln.) to prevent it from being attacked by metal alloyed with the Pb which is poured into the grid, in making electrodes as described in Brit. 284,352 (cf. preceding abstract). The coating also serves as a heat insulator.

Storage battery. ALFRED P. WOOD (a 0.49 interest to Francis L. Murray). U. S. 1,687,416, Oct. 9. Structural features.

Storage battery with an opaque casing and a transparent window to show the electrolyte level. G. H. TROTTER. Brit. 285,293, May 24, 1927. Structural features.

Electrolyte for storage batteries. A. B. WERBY (to American Automotive Corp.). U. S. 1,684,842, Sept. 18. An electrolyte is formed of H_2SO_4 and water, together with NH_4 acetate which serves to prevent sulfation. Sulfates of K, Mg and Na also may be used.

Composition for use in storage batteries. PATRICK J. KELLEHER. U. S. 1,685,674, Sept 25. A compn. for preventing sulfation of storage batteries comprises $MgSO_4$ 84, $(NH_4)_2SO_4$ 3, K_2SO_4 6 and $Al_2(SO_4)_3$ 7%. Cf. *C. A.* **21,** 861.

Charge indicator for storage batteries. W. R. PENROSE. Brit. 285,286, July 7, 1927. When the battery is fully charged, gases evolved force indicator liquid up the

longer limb of a bent tube and bubble through the liquid. The device may be mounted on the instrument board of an automobile.

Storage-battery plate. JASPER N. DAVIS. U. S. 1,685,215, Sept. 25. Structural features.

Wood pulp storage battery separators with ebonite ribs. C. N. WATERS. Brit. 284,853, Jan. 20, 1927.

Hydrometer for suspension from vent plugs of storage batteries. C. E. LINEBARGER. Brit. 284,916, May 27, 1927.

Electrodes for electric batteries, etc. RENE OPPENHEIM (to Soc. anon. le carbone). U. S. 1,687,307, Oct. 9. Electrodes for batteries, accumulators and electrolytic app. comprise a mixt. of granular active material such as Pb oxide compn. and another granular material such as silica gel which is permeable to gases and substantially impermeable to liquids. Cf. *C. A.* **21**, 2438.

Carbon electrodes for electric batteries. COMPAGNIE LORRAINE DE CHARBONS, LAMPES, ET APPAREILLAGES ELECTRIQUES. Brit. 285,415, Feb. 16, 1927. C electrodes are provided with discontinuous hollows or sinuous grooves to prevent sepn. of surrounding depolarizing material.

Selenium cells. J. NEALE. Brit. 284,942, Aug. 6, 1927. In making cells of the type in which cond. electrodes, preferably in the form of interdigitated combs or grids, are formed on an insulating base and coated with Se, the electrodes are formed so that they are relatively immovable by the method of "fusing-in" by which Au, Ag or Pt or all 3 metals are applied as in coating earthenware or china. Various details are given.

Gas cell. HENRI SPINDLER. Fr. 635,633, June 8, 1927. A gas cell working under very high pressures, *e. g.*, several hundred atms. is described. The electrolyte used may be KOH or a complex chloronitrate of Cu-Co made by adding HNO_3 to a mixt. of chlorides of Cu and Co.

Photoelectric cell for reproducing sound from a photographic record, etc. L. DE FOREST (to De Forest Phonofilms, Ltd.). Brit. 284,342, Jan. 29, 1927. Structural features.

Electric apparatus for various purposes, utilizing photoelectric cells. NEUFELDT & KUHNKE BETRIEBSGES. Brit. 285,062, Feb. 10, 1927.

Electrolytic rectifier. WM. C. READ (to Electro Metallurgical Co.). U. S. 1,684,684, Sept. 18. An electrolyte of 10-40% H_2SO_4 soln. contg. a metal sulfate such as $FeSO_4$ is used with a cathode contg. Si and Ti or like metal and an anode which may be formed of Pb or a Pb alloy.

Cellular accumulator. JEAN-MARIE LARGE. Fr. 635,600, June 7, 1927. Constructional details.

Treatment of glass in the electric arc. EMIL EDWIN (to Aktieselskapet Norsk Staal Elektrisk-Gas-Reduktion). Can. 283,385, Sept. 18, 1928. A cold electrode is located in the upper end of an upright flame tube, the lower end of which communicates with a molten bath of heat-resisting material forming a hot electrode. The gases to be treated enter the upper part of the flame tube and after passing through the high-tension elec. arc are discharged above the surface of the bath.

Electrodeposition of zinc from its sulfate solutions. I. G. FARBENIND. A. G. Brit. 285,373, Feb. 14, 1927. A $ZnSO_4$ soln. preferably contg. 15-25% free acid is electrolyzed at a low c. d. (suitably 200-500 amp. per sq. meter). With an electrolyte of this character improved extn. by lixiviation of zinciferous material is attained.

Apparatus for cleaning electroplate goods by heating. ANTON MAREK. Austrian 109,156, Nov. 15, 1927. Constructional details.

Electrolytic baths. ALLEN ELECTROLYTIC CELL CORPORATION. Fr. 635,192, June 3, 1927. Constructional features.

Purifying brine for electrolytic processes. JULIUS DRUCKER (to I. G. Farbenind. A.-G.). U. S. 1,687,433, Oct. 9. An alkali metal fluoride is added to ppt. Mg and Ca as fluorides.

Tank for chromium baths. CHROM INDUSTRIE MAX WOMMER. Fr. 635,699, June 9, 1927. A tank is formed with a hollow rim with holes opening into the tank through which the mist forming on the bath is drawn by suction.

Electrodeposition of chromium. W. S. EATON. Brit. 284,900, May 2, 1927. Cr is deposited from a bath contg. chromic acid and an alk. content mainly formed of NaOH. An alk. mixt. for addn. to the bath may, *e. g.*, be suitably formed of NaOH 94, Na_2SO_4 2, Na_2CO_3 2 and NaCl and impurities 2%. One oz. of this mixt. may be used with chromic acid crystals 1 lb. and water 1 gal. in forming the electrolyte. Before plating, the cathode is cleaned in an alk. bath while connected to a C plate, graphite rod or to Fe to form a couple. It is then rinsed and placed while wet in the plating

bath. A temp. of about 45–55°, voltage of 5–10 and c. d. of 1–2 amp. per sq. in. are suitable for the plating operation.

Electrolytic preparation of chromium. CHROM INDUSTRIE MAX WOMMER. Fr. 635,700, June 9, 1927. To the solns. of chromic acid or chromates, solubilized inorg. colloids are added to obtain pure adherent and homogeneous ppts. of Cr.

Chromium. GENERAL ELECTRIC CO., LTD., AND C. J. SMITHELLS. Brit. 285,571, Nov. 18, 1926. To form coherent bodies of Cr, the powd. material is pressed into bars and sintered in H at a temp. of 1500–1550°. The Cr powder may be prepd. by passing an elec. current of about 140 amp. per sq. decimeter through a soln. contg. 24.5% chromic acid and 0.3% chromic sulfate, using an anode of Pb and a cathode of Cu or Al, while the soln. is at a temp. of about 50°. The powder is washed and dried and heated at 1300° in H to reduce any oxide present. The H used may be purified by passing it over incandescent W and through a tube cooled in liquid O, and may be previously passed over Cu heated to redness and P_2O_5.

Aluminum. SOCIÉTÉ ANON. POUR L'IND. DE L'ALUMINUM. Fr. 635,541, June 4, 1927. Pure Al is obtained from crude Al or its alloys by electrolysis in a bath contg. Al halides and alkali and (or) alk earth halides, the Al salt being in excess. The process may be carried out in closed tanks under slight pressure.

Recovery of nickel and copper. CHEMISCHE FABRIK JOHANNISTHAL G.M.B.H. AND FRIEDRICH TROSTLER. Fr. 635,804, June 11, 1927. See Brit. 283,132 (*C. A.* **22,** 5817).

Electrolytic separation of silver from alloys. RUDOLF CARL. U. S. 1,687,056, Oct. 9. Alloys of Ag with other metals such as Au, Zn and Cu are treated as anode in aq $NaClO_4$ soln. or other suitable neutral electrolyte, the anion of which is capable of forming with the Ag and base metal of the alloy easily sol. salts, so that hydroxyl ions are released at the anode and form oxides of the precious metals present and hydroxides of the base metals; the H released at the cathode reduces the Ag oxide to a finely distributed Ag which does not adhere to the cathode.

Alkaline hypochlorites. FERNAND CHEVRIER. Fr. 635,654, Dec. 21, 1926. In the electrolytic prepn. of NaOCl a high anodic tension is employed so that ozone is also produced.

Magnesium and alkaline earth metals by electrolysis of molten chlorides. ALFRED JESSUP Fr. 32,645, Apr. 22, 1926. Addn. to 613,930. The C or graphite anode is replaced by an intermediate alloy of Mg. Cf. *C. A.* **22,** 1285

Lead sulfate. AMÉDÉE P. CASSOU. Fr. 635,134, May 30, 1927. $PbSO_4$ is prepd. by electrolyzing with Pb electrodes, at a temp. below 40°, an aq. soln. of H_2SO_4, contg. in soln. a catalyst which is either a Pb sulfide, or an alkali sulfide or a sol. or slightly sol Pb compd., or mixts. of these products.

Electrolysis of water. FRANZ LAWACZECK. Fr. 635,660, Apr. 12, 1927. The pairs of electrodes are arranged in tiers Other constructional details are described.

Electrolytic decomposition of salts. A. I. NOVIKOV. Russ. 3764, Oct. 31, 1927. An electrolytic bath subdivided by semipermeable partitions is used for the decompn. of salts into acid and caustic. Acid used for the anolyte has the anion which is different from that of the anion of the salt to be decompd. The salt is introduced into a compartment near the catholyte according to the amt electrolyzed.

Electrolytic rectifier. EDGAR W. ENGLE (to Fansteel Products Co.). U. S. 1,686,316, Oct. 2. Electrodes of Rh and Ta are used with an electrolyte contg. H_2SO_4 and a small proportion of $FeSO_4$ or like salt. Cf. *C. A.* **22,** 3591.

Tinning. PIETRO MARTINELLI. Ital. 250,882, Oct. 15, 1925. Electrolytic bath for the galvanic tinning of metals.

Metal production in an electric furnace. EMIL G. T. GUSTAFSON (to Hampus G. E. Cornelius). Can. 283,819, Oct. 2, 1928. An elec. furnace is fettled and a quantity of slag, tapped from a previous heat, is introduced and held in a molten state until a sufficient quantity of charge for the next heat has been introduced, in order to protect the bottom of the furnace from the action of the elec. arc and to act as a distributor for the charge.

Electric furnace. CORNELIUS E. CORNELIUS. Can. 283,657, Oct. 2, 1928. An elec. furnace for melting and producing glass, water glass, cement, etc., is described.

Electric furnace. ELECTRIC FURNACE COMPANY. Fr. 635,966, June 14, 1927.

Electric furnaces. METALLWERK PLANSEE G.M.B.H. AND PAUL SCHWARZKOPF. Fr. 636,025, June 15, 1927. See Brit. 272,933 (*C. A.* **22,** 1737).

Electric furnaces. SOCIÉTÉ ÉLECTRO-MÉTALLURGIQUE DE MONTRICHER. Fr. 32,758, Dec. 21, 1926. Addn. to 608,835. Constructional improvements.

Small electric reheating furnace. JACQUES SCHMID. Fr. 636,032, June 15, 1927.

Electric induction furnace of the crucible type. CHARLES B. FOLEY (to Charles B. Foley, Inc.). U. S. 1,685,914, Oct. 2. The furnace is formed of 2 united blocks, each made in the form of a half crucible and formed of highly compressed refractory material.

Electric induction furnace of the submerged resistor type. EDWIN F. NORTHRUP (to Ajax Metal Co.). U. S. 1,684,504, Sept. 18.

Electric resistance furnace. H. WIGGIN & CO., LTD., AND A. G. LOBLEY. Brit. 285,147, Nov. 11, 1926. Resistance strips of Ni-Cr alloy may be suspended by hooks of the same material. Various other structural features also are specified.

Electric furnace (resistance heated, having a vertically movable hearth, and suitable for operating with an inert atmosphere). ALLGEMEINE ELEKTRICITÄTS-GES. (to International General Electric Co.). Brit. 284,350, Jan. 29, 1927. Structural features.

Electric furnace for producing silicon carbide. HAROLD E. WHITE (to Federal Abrasives Co.). U. S. 1,684,611, Sept. 18. A hearth is provided with concrete supports and the furnace also has concrete end walls free of any fixed connection with the hearth supports.

Electrolytic furnace. P. L. HULIN. Brit. 284,678, Feb. 3, 1927. Structural details are specified of a furnace adapted for electrolysis of chlorides or other compds of light metals such as Mg, Ca and Be.

Resistor support for electric furnaces. JOHANN SCHNEPF (to Westinghouse Elec. & Mfg. Co.). U. S. 1,686,037, Oct. 2. Structural features.

Electric heating units for metallurgical multiple hearth furnaces or similar apparatus. CHARLES L. BURDOCK (to Guggenheim Bros.). U. S. 1,685,226, Sept. 25. Structural features.

Apparatus for making self-baking electrodes for electric furnaces. MARTIN WALTHER (to Det Norske Aktieselskab for Elektrokemisk Industrie of Norway). U. S. 1,686,302, Oct. 2.

Self-baking electric furnace electrodes and holders and contacts for the electrodes. CARL W. SÖDERBERG (to Det Norske Aktieselskab for Elektrokemisk Industrie of Norway). U. S. 1,686,474, Oct. 2. Structural features.

Anodes. ERNST KELSEN. Fr. 635,771, June 10, 1927. Anodes for galvanization are made by compressing metal waste into the form of plates.

Heat-control system for electric ovens. JACOB L. SHROYER (to Edison Electric Appliance Co.). U. S. 1,685,647, Sept. 25.

"Cyanamide oven" for making blocks of calcium cyanamide and other materials. GEORGE E. COX (to American Cyanamide Co.). U. S. 1,684,758, Sept. 18.

Heat- or pressure-responsive device for controlling electric circuits. LESTER E. BECK. U. S. 1,685,211, Sept. 25.

Pressure-controlled device for electric switches, valves, etc. FRANK J. BAST (to Charles J. Tagliabue Mfg. Co.). U. S. 1,684,530, Sept. 18.

Electric recording device. W. C. SUTHERLAND and J. DENTON (to Keighley Dye Works). Brit. 285,114, Nov. 5, 1926.

Electric heater for liquids. ÖSTERREICHISCHE SIEMENS-SCHUCKERT-WERKE. Austrian 109,101, Nov. 15, 1927. Constructional details.

Apparatus for electrically heating liquids. GUSTAV BAUM (to Niagara Electro Chemical Co.). U. S. 1,685,210, Sept. 25. An app. is described which is suitable for use in distg., concg. or effecting reactions.

Electric heating of liquids for distillation, concentration, promoting reactions, etc. GUSTAV BAUM (to Niagara Electro Chemical Co., Inc.). U. S. 1,685,266, Sept. 25. H_2SO_4 to be purified or other liquid is absorbed in a porous non-cond. material and an elec. current is then passed through the absorbed liquid. An app. is described.

Protective cut-out device for oil-immersed electrical transformers, etc. T. A. E. BELT (to British Thomson-Houston Co., Ltd.). Brit. 284,630, Feb. 1, 1927. Gas evolved as a result of internal faults in the app. serves to displace oil in a tube and thus permit change in intensity of a beam of light passing to a photoelec. cell which in turn may operate an alarm or cut-out device.

Inert-gas protective casing for hydrogen-cooled dynamo-electric apparatus. FRANK D. NEWBURY (to Westinghouse Elec. & Mfg. Co.). U. S. 1,686,027, Oct. 2.

Electric system for effecting magnetic separations. B. GRANIGG. Brit. 284,307, Jan. 28, 1927.

Electric treatment of gaseous products evolved in carbonizing marine algae. G. J. B. CHAMAGNE. Brit. 284,583, Aug. 11, 1926. An elec. pptn. app. is described for recovery of pptd. and condensed substances from the gases produced in the carbonization. Cf. *C. A.* 22, 3501.

Electric filament device for consuming gases in cable tunnels, etc. HENRY C. P. WEBER (to Westinghouse Elec. & Mfg. Co.). U. S. 1,686,051, Oct. 2. A filament is used formed of material such as Ni capable of causing the combustion of sewer gas or other gaseous mixts. at temps. of 600–800° and this filament is secured to a base adapted to fit into an ordinary elec. lamp socket and is provided with a housing comprising a Davey safety lamp diaphragm which provides a combustion chamber for the filament.

Material for rectifying electric currents. WALTER O. SNELLING. U. S. 1,686,260, Oct. 2. Pressure is applied to pptd PbS or other similarly acting finely divided compd. of a metal with an element of the S group and the resulting coherent product is thereafter heated to a temp. sufficient to produce partial crystal growth, but lower than a sintering temp. A temp. of about 50–100° below its m. p. is suitable with PbS.

Hydrogenating hydrocarbons, etc. F. J. M. HANSEN. Brit. 284,655, Feb. 2, 1927. Hydrogenation of hydrocarbons such as $C_{10}H_8$, carbonaceous gases such as water gas or of C is effected by the action of an elec. arc or a series of elec. sparks from a condenser discharge between electrodes which are immersed in a solvent for the products which may be circulated in a closed circuit through either a cooling device or a still for recovery of certain of the products. H or material to be hydrogenated may be supplied through hollow electrodes and the electrodes or some of them may contain a hydrogenating catalyst such as Ni or a Ni compd. Coal or coke to be hydrogenated may be molded into electrodes with addn. of a metal salt or inclusion of a metal wire. The process may be carried out under about 10 atm. pressure.

Purifying solutions of aluminum salts. FRANCESCO GIORDANI (to Pomilio Bros. Corp.). U. S. 1,685,156, Sept. 25. Solns. of Al salts such as those obtained by acid treatment of leucite are freed from impurities such as Fe by electrolytic treatment, employing an Al electrode together with another electrode adapted to act as a positive electrode for a metal to be eliminated and which may suitably be formed of graphite for the elimination of Fe.

Liquid resistance. V. V. PLOTNIKOV. Russ. 3621, Sept. 30, 1927. Water-cooled glass tubes are filled with an electrolyte soln. (NaCl). Through the fused upper and lower ends of these tubes wires connect one plate on the bottom and corresponding contacts on the top of the cooling container. The electrolyte in the tubes acts as resistance.

Arc lamp electrodes. COMPAGNIE LORRAINE DE CHARBONS POUR L'ELECTRICITE (formerly Compagnie Lorraine de charbons, lampes, et appareillages electriques). Brit 285,424, Feb 16, 1927. Mineral substances are incorporated with the C to permit a c. d in excess of 1 amp. per sq. mm. These substances may be used in a core or may be uniformly distributed throughout the electrode material and may comprise oxides, fluorides or oxy-fluorides of the rare earth metals, especially those of the Ce group, and small quantities of H_3BO_3 or refractory compds. of Ti, W, Zr and V may be added. Oxides of Ca, Mg, Be, Zr, Al and Th also may be used and may partially replace the rare earth compds. The added mineral substances may comprise 50–55% of the electrode material.

Electric incandescent lamps. PATENT-TREUHAND-GES. FÜR ELEKTRISCHE GLÜHLAMPEN (to General Electric Co., Ltd.). Brit. 284,203, Jan. 26, 1927. To facilitate accurate proportioning and subdivision of "gettering" material it is mixed with a binder such as nitrocellulose soln. and formed into ribbons, filaments or the like.

Electric incandescent lamps. PATENT-TREUHAND-GES. FÜR ELEKTRISCHE GLÜHLAMPEN (to General Electric Co., Ltd). Brit. 285,009, Feb. 8, 1927. The caps of the lamps are provided with a heat-resisting coating which protects them from oxidation and may be formed of waterglass, borax or Na-NH_4 phosphate. NH_4 bifluoride may be used as an etching liquid to remove the coating locally where it is desired to attach soldered connections to the coated caps.

5—PHOTOGRAPHY

C. E. K. MEES

The use of light-sensitive organic compounds in photography. A. SEYEWETZ. École de chimie industrielle, Lyon. *Chimie et industrie* 20, 216–20(1928).—A brief review. A. PAPINEAU-COUTURE

Photographic transfer papers. T. P. MIDDLETON. *Brit. J. Phot.* 75, 495–7, 512 3(1928).—Description of methods of prepn. of emulsion-coated photographic papers.

Details are given for making slow and fast emulsions. Two methods of ripening are described: (*a*) the "boiling," and (*b*) the NH_4OH method. App. for shredding and washing emulsions are illustrated and directions for their use given. A table of chem. equivs. for emulsion making and a bibliography are appended. G. E. MATTHEWS

Machine processing of photographic papers and films. F. WENTZEL. *Z. Ver. deut. Ing.* **72,** 1017–24(1928).—Well-illustrated description of various types of machines for processing papers and films on a commercial scale. Types of exposing, developing, washing and drying machines are described including the more complicated automatic app. combining several operations such as photostat and multiple postcard systems. C. E. MEULENDYKE

Photographic preparation of printing plates. K. SCHUCH. *Chem.-Ztg.* **52,** 485–6 (1928).—Practical details are given for the prepn. of printing plates using asphalt and dichromated gelatin, albumin and fish glue. W. CLARK

Developing properties of diphenylamine derivatives. A. LUMIÈRE, L. LUMIÈRE AND A. SEYEWETZ. *Sci. ind. phot.* **8,** 28–32(1928); *Chimie et industrie* **Special No.,** 496–500(April, 1928).—The authors conclude that: (1) Substitution of a phenyl group in an amino group of *p*-phenylenediamine or of *p*-aminophenol to form the *p*-amino or *p*-hydroxyl derivs. of diphenylamine does not destroy the developing properties but causes them to be diminished; (2) the introduction of amino or hydroxy groups in the substituted phenyl group increases the developing power of the compd ; (3) the developing properties of diphenylamine are destroyed when a phenyl group is substituted for O, S, or N in the *o*-position to the common amino group although the compd. formed would be "quinonizable." The substituted compds. are the leuco bases of the oxazines, thiazines and azines. L. E MUEHLER

Observation on the fogging action of desensitizers. M. MUDROVEIC. *Phot. Ind.* **26,** 782(1928) —Evidence points to the fact that desensitizers with a free amino group do not fog an emulsion while those that have substituted amines do fog emulsions Many explanations are mentioned M. suggests that the fogging is caused by the coagulation of the Ag amicrons, thus forming particles large enough to promote development. The inhibiting effect of other dyes present is explained by diln. C. E. MEULENDYKE

Optical sensitizing of silver halide emulsions. I. Adsorption of orthochrome T to silver bromide. S. E. SHEPPARD AND H. CROUCH. *J. Phys. Chem.* **32,** 751–62; *Phot. J.* **68,** 273–80; *Sci. ind. phot.* **8M,** 24–7, *et seq.*(1928).—The absorption spectra in the visible and ultra-violet of orthochrome T bromide have been measured in solvents and in H_2O at various p_H values. The adsorption of the dye to AgBr was measured by mixing the 2 in various concns. and then sepg. the phases The grain size frequency of the AgBr was known so the ratio of moles of dye per sq. cm. of surface of the grains could be calcd Langmuir's adsorption equation was the only one found to fit the exptl. detn. As to the sensitizing of the AgBr it is suggested that the dye is held to the AgBr ion and that the photodecompn. is of an explosive character, thus one dye mol. could sensitize many AgBr mols. H. CROUCH

The relation between the photoelectric and the photographic effect in silver bromide. L. W. BUTLER. Ia. State Col., Ames. *Proc. Iowa Acad. Sci.* **34,** 277(1927).—Toy, Edgerton and Vick (*C. A.* **21,** 1223) have recently shown that the photoelec. effect in AgBr is due to ultra-violet light of wave-length less than $\lambda = 280\ m\mu$. Since the photographic effect extends to $\lambda = 500\ m\mu$ they concluded that there is no relation between the photoelec. and the photographic effects in AgBr. Before this article appeared, B. had obtained approx. the same result with AgBr formed by fuming the surface of a Ag plate. His data were obtained by the use of more sensitive app. than that employed by the above-named investigators. In order to prevent deterioration of the AgBr the plate was kept in complete darkness until the time of exposure by which measurements were made. W. G. GAESSLER

Saving overexposures on self-toning paper. ANON. *Assoc. Belge Phot.* **50,** 3–4 (1928).—Overexposed prints on self toning paper may be saved by bathing in a 5% $K_2Cr_2O_7$ soln., followed by rinsing and fixing in 10–15% $Na_2S_2O_3.5H_2O$. The treatment may be applied to citrate paper. L. E. MUEHLER

Colored films (Brit. pat. 285 431) 25.

Photographic films. I. G. FARBENIND. A.-G. Fr. 635,281, Apr. 28, 1927. See Brit. 270,347 (*C. A.* 22, 1552).

Nonstatic photographic film. PAUL C. SEEL (to Eastman Kodak Co.). U. S.

1,687,041, Oct. 9. An electrifiable film such as a pyroxylin compn. carries a light-sensitive coating on one side and on the other side is provided with an antistatic layer contg. paratoluene sulfonamide-formaldehyde resin. U. S. 1,687,042 specifies the similar use of an antistatic film contg. an abietic acid ester such as that of glycerol.

Eliminating static charges from cinematographic films. PALMIRE H. NICOLLIC AND MAURICE J E. CLAUDE. Fr. 635,152, Sept. 29, 1926. The space surrounding photographic or cinematographic films is ionized with feebly radioactive substances emanating from relatively large surfaces to discharge electrostatic charges on the films.

Two-color cinematograph films. J. E. THORNTON. Brit. 285,262, March 8, 1927. A film of the kind described in Brit. 213,647 (*C. A.* **18,** 2476) which is built up by cementing together 2 thin films, each comprising a transparent support carrying a component image in colored colloid relief produced by printing on a ready-colored colloid layer which is developed to remove the unexposed portions of the colloid, is made up by cementing the 2 thin films together with their supports in contact.

Films for color photography. J. E. THORNTON. Brit. 285,227, Jan. 20, 1927. Film material for the production of multicolor cinematograph or other films built up from printed colloid layers without supports as described in Brit. 285,228 (following abstr.) comprises a web of double, triple or quadruple material, the usual width formed by applying to a temporary strippable paper support a colloid film layer which may be non-sensitized so that it must be sensitized before use as by immersion in a Ag, dichromate, Fe or U sensitizer or may be ready sensitized with Ag salts, and may, in either case, be ready colored in stripes of different color. Numerous details are given. Cf. *C. A.* 22, 1739.

Color photography. J. E. THORNTON. Brit. 285,228, Jan. 28, 1927. Positive multicolor films of standard thickness are produced by cementing together in register, with a colloid or cellulose cement, color-record components printed on thin film strips formed of ready-colored sensitized colloid only, without the usual supporting layer. Numerous details are given.

Color photography. SOC. DU FILM EN COULEURS KELLER-DORIAN. Brit. 284,995, Feb. 7, 1927. Optical features.

Color photography. SOC. DU FILM EN COULEURS KELLER-DORIAN. Brit. 285,035, Feb. 9, 1927 In reproducing, by optical projection followed by reversal of the developed copy, color-record images made on films with lenticular elements, a copy is produced having contrasts equal to those of the original image by transforming this image, before copying, into an image having reduced contrasts by subjecting it to reactions such as toning the Ag image either chemically or by mordanting or conversion of the Ag into chloride, bromide, iodide or ferrocyanide

Colored photographs. WM. F. FOX (to Natural Color Pictures Co.). U. S. 1,685,-281, Sept. 25. A positive and a negative image are printed in alignment in a single coating of sensitive emulsion on one side of a suitable base, with unaffected emulsion sep. the images and with the positive image undermost; both images are toned one color, *e. g.*, by salts of V and Fe, and the emulsion material is hardened in proportion to the amt. of tone; the film is dyed with a dye of a second color, *e. g.*, with an acid red dye adapted to act most vigorously on the soft portions of the film.

Photographic sensitive papers. R. SCHWICKERT GES. AND E. BURG. Brit. 284,253, Jan 26, 1927. Light-sensitive layers which can be developed by gases or vapors such as NH_3 or steam contain a hygroscopic substance to accelerate development. Sensitive layers for development with NH_3 may, *e. g.*, comprise diazotized amide acid, resorcinol, $KHSO_4$ and NaOAc or diazotized H acid, H acid, K biphosphate and $MgCl_2$. Lime is also proposed as a hygroscopic substance.

Making composite colored pictures. ROY J. POMEROY (one-half to Famous Players Lasky Corp.). U. S. 1,686,987, Oct. 9. An image of one component of a picture is made on a limited area of a ground and the image area is colored substantially uniformly in a selected color such as mixed naphthol green and "patent blue" to transmit substantially only light of that selected color; the surrounding ground is colored substantially uniformly in a color such as red having a minus relation to the selected image color so that the ground will transmit predominately light of the last mentioned color, an image of another component of the picture is made and the 2 components are selectively printed onto different parts of a fresh actinic surface with printing light of the 2 specified colors.

Polychromatic screen for use in photographic color processes. JOHN G. CAPSTAFF (to Eastman Kodak Co.). U. S. 1,687,055, Oct. 9.

6—INORGANIC CHEMISTRY

A. R. MIDDLETON

Valency. X. Electrometric titration of Vernon's α- and β-dimethyltelluronium bases. FRANK L. GILBERT AND THOMAS N. LOWRY. Univ. of Cambridge. *J. Chem. Soc.* **1928**, 1997–2010; cf. *C. A.* **22**, 1899.—The relative strengths of the isomeric α- and β-$TeMe_2(OH)_2$ were compared by measuring the mol. conds. at 25°. That of the former varied from 3 to 6, while that of the latter varied from 31 to 36 in the range of v = 32–512. These values were increased to about 40, at v = 32, by satn. with CO_2 but were reduced to normal values again by passing a current of purified air through the solns. Cond. titrations of the bases with HCl showed a break at the compn. corresponding to $[TeMe_2OH]Cl$ but there was no indication of the formation either of the normal salt or more basic compd. Potentiometric titrations of the α-base with a glass electrode showed the typical behavior of a weak base, the formation of a nearly neutral hydroxy salt. They gave no indication of the formation in soln. of the dioxyiodide which Vernon prepd. in cryst. form The curve for the β-base, on the other hand, showed a break at about 50% neutralization with HCl, corresponding to the formation of a basic salt, $2TeMe_2O.HCl$, which has not been obtained in the free state. H. F. J.

Free inorganic radicals. P. WALDEN AND L. F. AUDRIETH. Cornell Univ. *Chem. Reviews* **5**, 339–59(1928).—A discussion of the methods of prepn., and phys. and chem. properties of the *halogenoids*, including the formation of compds. with the halogens and among themselves (*interhalogenoids*). The following compds. are described $(SCN)_2$; $(CN)_2$; $(SeCN)_2$; $(OCN)_2$; $(SCSN_3)_2$, *azidocarbon disulfide;* CsI_2CN; CNN_3. CN.SCN; $CN.SCSN_3$; CN.SeCN. Other evidence in support of the halogenoid analogy is offered, such as the existence of *sulfuryl azide*, $SO_2(N_3)_2$, and *carbonyl azide*, CO $(N_3)_2$. The contrast between the halogenoids and $(NO_2)_2$ is considered. H. S.

Supplement to our contribution: Regarding the radical-like alkali salts of a new nitrogen oxy-acid. E. ZINTL AND O. KOHN. *Ber.* **61B**, 2063(1928); cf. *C. A.* **22**, 1292.—Na_2NO_2 reacts in H_2O to form hyponitrite, N_2 and N_2O and not H_2 as indicated by Maxted (cf. *C A.* **12**, 455). The authors claim that Maxted probably found NaOH, $NaNO_2$ and H_2 and no hyponitrite because Na_2NO_2 decomposes when moist N_2 is passed over it. B. E. ROETHELI

Investigations concerning the reactions in solutions of weak inorganic acids which have a tendency to form aggregates. GERHART JANDER. *Z. angew. Chem.* **41**, 201–3 (1928).—Summary of a lecture on the complex acids and alkali salts of W, Sb, Ta, Si and Cr. References are given. E. R. SMITH

The rare earths. [The oxidation of the oxalates of praseodymium and neodymium]. JOSEF ŠVÉDA. Charles Univ., Prague. *Časopis Československého Lékárnictva* **7**, 226–32(1927).—The decompn. of oxalates by heating in O_2 is easily effected at low temps., the product always contains some carbonate. The attainment of const. wt. does not indicate that decompn. is complete. The decompn. of Pr oxalate is effected at a lower temp. and more completely than that of Nd oxalate. In a mixt. of the oxalates (Pr_2O_3 : Nd_2O_3 = 1:1) the decompn. of Nd oxalate is greatly accelerated, but for complete decompn. a higher temp. is required than for the individual oxalates. By calcination of Pr oxalate in O_2, there is formed a dark brown oxide, Pr_6O_{11}, which on calcination *in vacuo* yields O_2 and Pr_2O_3; the latter reoxidizes easily in presence of traces of Pr_6O_{11}. Similar calcination of Nd oxalate yields only Nd_2O_3, contrary to the results of Waegner (*Z. anorg. Chem.* **42**, 118). In calcination of a mixt. of the oxalates of Nd and Pr, the presence of Nd does not interfere with the formation of the higher oxide of Pr, contrary to the results of Marc (*Ber.* **35**, 2370). WILLIAM J. HUSA

Indium. III. A. THIEL AND H. LUCKMANN. Marburg Univ. *Z. anorg. allgem. Chem.* **172**, 353–71(1928).—In is sepd. from other metals by pptn. as hydroxide. Fe and some Cd are still present. The In is treated with excess of NH_3 to remove Cd and with H_2S in acid soln. to remove Fe and Al. Gelatinous In hydroxide is digested on the water bath to form a granular material. Electrolytic deposition of In can be used but the method is not quant. The metal obtained in this way when fused in an inert atm. gives appreciable amts. of water. Extn. of the In as In_2O_3 is exact if certain conditions are followed, this being also true for In_2S_3. In_2O_3 is difficult to obtain pure, its density is 6.75 ± 0.01 and its color is yellow. In_2O, which strongly heated in air transforms to the yellow In_2O_3, is also yellow. T. and L. doubt Winkler's In_4O_5 and In_7O_9 and consider these are represented by InO which they obtained by reducing In_2O_3 with H. In_2S_3 is noticeably volatile at 850° and m. 1050° ± 3°. In_2S_3 m. 653° ± 5° and its density is 5.92 ± 0.01. InS is volatile at 850° and the existence of other

sulfides is indicated by m.-p. detns. of mixts. of In and S. InO is the lightest colored oxide and In_2O is the darkest. In_2O and In_2S are paramagnetic; InO and InS are less so; In_2O_3 and In_2S_3 are indifferent. S. L. B. ETHERTON

Reduction of metallic oxides, and the equilibrium $Zn + CO_2 \rightleftharpoons ZnO + CO$. KARL JELLINEK AND BORIS POTIECHIN. Techn. High School, Danzig. *Z. anorg. allgem. Chem.* **173**, 164–8(1928).—Reduction of sulfides and halides gives easily reproducible equilibria with H but this is not the case with oxides. In the case of CdO and H_2 at 270°, the gases drawn off have 125 vol. % H_2O and 75 vol. % H_2. At 309° they have 55 vol. % H_2O and hence the reaction isochore equation is $\log 25/75 - \log 55/45 = Q/457$ $[(1/545) - (1/582)]$, whence $Q = -21{,}500$. J. and P. examd. $Zn + CO_2 \rightleftharpoons ZnO + CO$ and found at 400–600° almost 100 vol. % of CO when CO_2 was passed over pure ZnO and Zn. For more accurate figures the CO side of the equil. was examd. Pure CO was made by passing pure CO_2 over Zn dust and the residual CO_2 was absorbed in concd. KOH, then in $Ba(OH)_2$ and passed through concd. H_2SO_4 and over P_2O_5. At 565° and atm. pressure, 0.2 vol. % of CO_2 was obtained by passing CO over ZnO. The quantity of CO_2 should be higher and also the vapor of Zn at 565° is 5 mm. so that CO_2 could react with Zn in cold parts of the app. Ch. G. Maier and O. C. Ralston obtained 0.05 vol. % of CO_2, a value even lower than the supposed low value of J. and P. The latter ascribe the difference in values to difference in the ZnO modification used. S. L. B. ETHERTON

Action of phenylhydrazine on oxides and salts of metals. Lead suboxide. II. ERNESTO PUXEDDU. R. Univ. Cagliari. *Gazz. chim. ital.* **58**, 224–31(1928); cf. *C. A.* **10**, 2883.—The unsatisfactory results obtained by other investigators in the formation of Pb_2O from PbC_2O_4 induced P. to attempt its formation by reduction of higher oxides of Pb with $PhHNNH_2$. Expts. show that a large excess of pure $PhHNNH_2$ reduces PbO_2, Pb_3O_4 and PbO to Pb_2O. PbO and $PhHNNH_2$ heated slowly up to 150°, then cooled to 80°, and the alternate heating and cooling between 80° and 150° continued for 1 hr. and the product washed with EtOH and with Et_2O to remove org. impurities yields Pb_2O as a black-brown unctuous powder. If the temp. exceeds 150° or if maintained too long a time at this temp., Pb is formed. Pb_3O_4 does not react with $PhHNNH_2$ at room temp. in darkness, but in sunlight reduction takes place. By heating the mixt. to 150° and proceeding as with PbO, Pb_2O is formed. Pb_2O behaves differently, a violent reaction taking place even at room temp., a mixt. of PbO, Pb_2O and Pb being formed. However, PbO_2 (3 g.) and $PhHNNH_2$ in Et_2O (15 g. in 10 g.) at room temp. for a day form PbO, while if this mixt. is heated to 150°, Pb_2O is formed (after the Et_2O has evapd.). In all these prepns. the products must be washed with EtOH and with Et_2O. The *reduction of $HgCl_2$ and of HgCl by $PhHNNH_2$* was then attempted. Et_2O solns. of $PhHNNH_2$ and of $HgCl_2$ ppt. a yellowish white *compd.*, probably $Hg(NHNHC_6H_4Cl)_2$ and therefore analogous to the $PhNH_2$ deriv. Both $HgCl_2$ and HgCl are reduced to Hg by excess $PhHNNH_2$. $PhHNNH_2$ offers a means for the *detn. of Hg in $HgCl_2$ and in HgCl. In $HgCl_2$.*—Warm gently the $HgCl_2$ and $PhHNNH_2$ for 30 min., then heat at 80° for 15 min., wash the Hg repeatedly first with acidulated water, then with EtOH and finally with Et_2O, dry over KOH (with Hg vapor present) and weigh. *In HgCl.*—The procedure is essentially the same as that for $HgCl_2$. This method gives precise results. C. C. DAVIS

Oxides of iron, especially ferrous oxide. H. GROEBLER AND P. OBERHOFFER. *Stahl u. Eisen* **47**, 1984–8(1927).—The purest prepn. of FeO obtained by heating Fe_2O_3 in a stream of CO and CO_2 at 800° contained 99% FeO when only small quantities (1 g.) of material were used. By heating at 900° the prepn. contained about 15% of metallic Fe, about $^2/_3$ of which could be removed by treating the mixt. with I soln.; the residual FeO contained only 95% FeO. The m. p. of FeO, as detd. by extrapolation from the results obtained with various impure specimens, is 1377°. Röntgenographic examn. of oxides of Fe prepd. by reduction of Fe_2O_3 at 800° shows that the limit of soly. of FeO in ferrosoferric oxide is 5%; with more than 61% FeO the lattice structure of ferrosoferric oxide is entirely replaced by that of FeO, which, therefore, appears to hold 39% Fe_3O_4 in solid soln. FeO retains only traces of Fe in solid soln. B. C. A.

Structure of boron hydrides. GEO. GLOCKLER. Univ. of Minn. *Science* **68**, 305–6(1928).—The idea of the pseudo-atom (cf. Grimm, *C. A.* **20**, 867) is extended to the hydrides of B. The pseudo-atoms in the chemistry of B are related to those in the chemistry of C as follows: $=BH=$ similar to $=C=$, $=BH_2-$ to $=CH-$, $-BH_3-$ to $-CH_2-$ and BH_4- to CH_3-. B_2H_6 would, therefore, be similar to C_2H_4 in that it contains the double bond but differs from it in the complexity of the positive charge within the octet. H. F. JOHNSTONE

Addition compounds of bivalent metal halides and organic bases. V. G. SCAG-

LIARINI AND E. BRASI. Univ. Bologna and Univ. Ferrari. *Atti. accad. Lincei* [6], 7, 411-3(1928).—The influence of the relative concns. of hexamethylenetetramine and of Hg halide on the formation of addn. compds. were detd. Cold, satd. $C_6H_{12}N_4$ in acetone added slowly to satd. $HgCl_2$ in acetone forms at first a white ppt., which microscopically has a characteristic crossed structure. On continued addn. of $C_6H_{12}N$, a very fine ppt. is formed, which microscopically has a structure differing from the ppt. of the earlier stages of the pptn. Analyses of the first and the last portions pptd. showed that 2 compds. are successively formed, *viz.*, the *compd.* $3HgCl_2.2C_6H_{12}N_4$ and the *compd.* $2HgCl_2.C_6H_{12}N_4$. Addn. of cold concd. $HgBr_2$ (1 mol.) in acetone to concd. $C_6H_{12}N_4$ (2 mols.) in acetone pptd. the *compd.* $HgBr_2.2C_6H_{12}N_4$. Under similar conditions but with equimol. proportions, the *compd.* $HgBr_2.C_6H_{12}N_4$ was formed. Cold concd. HgI_2 in acetone added to concd. $C_6H_{12}N_4$ in acetone pptd. the *compd.* $HgI_2.C_6H_{12}N_4$. Because of very slight soly. of HgI_2 in acetone, it was necessary, in order to carry out the reaction in the presence of excess HgI_2, to agitate cold concd. $C_6H_{12}N_4$ in acetone with solid HgI_2, adding $C_6H_{12}N_4$ soln. until the HgI_2 was just consumed. Under these conditions, there was pptd. the *compd.* $3HgI_2.2C_6H_{12}N_4$. C. C. D.

The interaction of cuprous chloride and the chromates of potassium in a solution of sodium chloride. HUBERT J. P. VANN AND VERNON EDGE. Tech. College of Salford. *J. Chem. Soc.* **1928**, 2142-6.—When a dil. soln. of $K_2Cr_2O_7$ was added to Cu_2Cl_2 dissolved in concd. NaCl soln. a green ppt. was formed. Basic cupric chlorides and $Cr(OH)_3$ were probably products of the reaction. When K_2CrO_4 was substituted for the $K_2Cr_2O_7$ the reaction did not go to completion and, besides the products mentioned above, $Cu(OH)_2$ was formed. When the Cu_2Cl_2-NaCl soln. was added to the $K_2Cr_2O_7$ soln. a brown ppt. was formed and the products contained a basic cupric chromate and $Cr(OH)_3$. If K_2CrO_4 was substituted for the dichromate in this case $Cu(OH)_2$ was formed in addn. to the above-mentioned products. H. F. JOHNSTONE

The binary systems of rubidium chloride with strontium chloride, barium chloride and cadmium chloride. FRIEDRICH HOFMANN. *Neues Jahrb. Min. Abt. A, Beil.-Bd.* **55**, 149-62 (1926-7).—In the system RbCl-$SrCl_2$ the following phases were found: RbCl (m. 715°), $RbCl.SrCl_2$ (congruent m. p. at 674°), $RbCl.2SrCl_2$ (congruent m. p. at 646°), $SrCl_2$ (m. 868°); for the system RbCl-$BaCl_2$: RbCl (m. 715°), $2RbCl.BaCl_2$ (congruent m. p. 649°), $BaCl_2$ (monoclinic) transition temp. to cubic $BaCl_2$ at 923°, $BaCl_2$ (cubic) m. 948°; for the system RbCl-$CdCl_2$: RbCl (m. 715°), $4RbCl.CdCl_2$ (incongruent m. p. at 476°), $3RbCl.2CdCl_2$ (incongruent m. p. at 451°), $RbCl.CdCl_2$ (congruent m. p. at 495°), $CdCl_2$ (m. 565°). The thermal and optical method was used. J. F. S.

Nitrogen trifluoride. OTTO RUFF, JOSEPH FISCHER AND FRITZ LUFT. Tech Hochschule, Breslau. *Z. anorg. allgem. Chem.* **172**, 417-25(1928).—Many unsuccessful attempts have been made to obtain a binary N fluoride. NF_3 has now been obtained and its properties examd. Fused dry tech. NH_4 acid fluoride is electrolytically decompd at 125°. A Cu vessel contains the melt and in this is an inverted Cu cylinder which functions as the cathode. To this is attached an insulated graphite rod, the anode. Ten amps. at 7-9 v. were required. The resulting gas contained H_2,NF_3,N_2O,N_2,O_2 and O_3 and was led over granulated KF and then over pyrolusite to remove O_3, HF and water and then cooled to —75°. The more difficultly volatile components are thus removed and the residual gas is passed through 2 glass vessels, one cooled with liquid air and the other cooled with liquid air through which passed a current of chilled H. In the early stages of the research violent explosions occurred which shattered the glass app. The cause of this was traced to O_3; hence pyrolusite was used to convert O_3 to O_2 catalytically. After this no explosions occurred. Pure NF_3 is a colorless gas to —119°; below this it is a colorless mobile liquid and it freezes at —210°. The d. is 71.1. The gas is practically insol. in water at room temps. and is not changed by sparking. It is remarkably stable, does not attack glass, Hg, MnO_2 or potash. Sparked in the presence of water vapor it gives HF, HNO_2 and HNO_3. Sparked in the presence of H it gives N_2 and HF. S. L. B. ETHERTON

Iridium fluorides. O. RUFF AND J. FISCHER. *Z. Elektrochem.* **33**, 560-1(1927).—For the prepn. of IrF_6 and IrF_5 by the passage of pure gaseous F over heated finely powdered Ir, the metal was contained in a boat of calcined fluorspar supported in a tube of the same material and heated electrically. Vessels of fluorspar calcined at 1280° are resistant to F at high temps., and are readily worked mechanically by means of an emery wheel. For analysis of the hexafluoride, reaction with Na_2CO_3 in a Pt crucible was carried out at the temp. of liquid air. Subsequent heating to redness yielded insol. iridium oxide, which was reduced to the metal and weighed. The atomic ratio of Ir to F obtained in this way was 1:6.08. Some properties of IrF_6 and IrF_5 are described. B. C. A.

Studies in metallic nitrides and hydrides. I. I. Zhukov. *Ann. inst. anal. phys. chim.* (Leningrad) **3**, 600–40(1927); cf. *C. A.* **21**, 3800.—A no. of metals were heated in H_2, the quantities of this latter absorbed and the equil. pressures being measured. Na reacts with H_2 above 200°, a product of the compn. NaH being formed. Dissocn. pressures of the hydride were detd. to 4–5 mm. at 285°, 51 mm. at 350°, 75 mm. at 360°, 261 mm. at 390° and 585 mm. at 425°. Ce (99.7% Ce) reacts with H_2 above 300°, forming a compd. CeH_2. The dissocn. pressure is 1–2 mm. at 480–520°. The hydride, CeH_2, shows a very marked soly. for H_2. Its elec. cond. is very small. Expts. on Pd (as Pd foil and Pd black, the latter being prepd. by reduction of $(NH_4)_2$-$PdCl_4$ by hydrazine chloride in a weak alk. soln.) yielded at 0–90° results closely resembling those of Hoitsema (*Z. physik. Chem.* **17**, 1 (1895)). Z. suggests that a solid soln. of H_2 in Pd is formed at the temp. studied but that at higher temps. 2 solid phases of varying compn. are formed. Rh (as Rh black prepd. by reduction of Na_3RhCl_6 by hydrazine chloride in alk. soln.) shows at 0–100° a behavior similar to that of Pd, the H_2 pressure, when plotted against amt. absorbed, showing first an increase, remaining then approx. const. and increasing finally again. Z. concludes that, as in the case of Pd, Rh forms a solid soln. with H_2 Ir (as Ir black prepd. by reduction of $(NH_4)_2Ir_2Cl_6$ by hydrazine chloride) forms at 25° a solid soln. with H_2. The vols. of H_2 absorbed at atm. pressure and 25° by 1 vol. each of Pd, Rh and Ir are, resp., 734, 448 and 807. Absorption of H_2 by Os is negligibly small. G. B. Kistiakowsky

The reduction of metallic sulfides with carbon. N. Parravano and G. Malquori. R. Univ. Roma. *Gazz. chim. ital.* **58**, 279–89(1928); cf. *C. A.* **22**, 3817.—The production of metals from their oxides, by reduction with C, suggested the adaptation of the analogous reaction: $2\ MS + C \longrightarrow 2\ M + CS_2$, to the production of metals from their sulfides. As a beginning a theoretical study was made of the latter reaction from the static point of view, the kinetic point of view being too complicated to be considered at first. The reducibility of a sulfide depends upon the pressure of CS_2 in the reaction above, and a comparison of various sulfides shows that the higher the vapor pressure of the S (p_{S_2}) or the higher the ratio p_{H_2S}/p_{H_2} for the equil: $MS + H_2 \longrightarrow M + H_2S$, the more easily is the sulfide reduced by C. Values of p_{H_2S}/p_{H_2} can be found in the literature, and a comparison of the data gives the following order of reducibility: $Ag_2S > PbS > NiS > FeS > Cu_2S > MnS$. With Acheson graphite, CS_2 was first formed from Ag_2S, PbS, FeS and Cu_2S at 970°, 1100°, 1200° and 1300°, resp. In a similar way it is shown that the reducibility of metallic oxides by C increases with increase in the value of p_{O_2}. A comparison of the reducibility of various sulfides and oxides leads to the conclusion that not only p_{S_2} or p_{O_2} but also the dissocn. consts. of CS_2 or CO_2 and the tendency of the sulfides to dissolve in the metals play a part in the reducibility. With the method already described (cf. *C. A.* **22**, 2091), the values of p_{S_2} were found to be 4, 7.5 and 11.8 mm. of Hg at 423.5°, 431.5° and 439.5°, resp. The greater difficulty of reducing sulfides by C compared with oxides depends upon the fact that with sulfides no reducing gas corresponding to CO is formed. C. C. D.

Lithium sulfite and some derivatives. John A. N. Friend and Donald W. Pounder. Techn. College, Birmingham, Eng. *J. Chem. Soc.* **1928**, 2245–8.—Li_2SO_3.-H_2O was prepd by passing SO_2 into a suspension of Li_2CO_3 in H_2O. The salt may be obtained by evapn. over a H_2O bath or over H_2SO_4 in a vacuum, or preferably, by pptn. with alc. The hydrate deliquesces in the air and oxidizes to the sulfate. When heated to 180° it loses H_2O and the anhyd. salt is formed. This melts with decompn. at 455°. The addn. products of $LiHSO_3$ with Me_2CO and BzH were obtained by passing SO_2 into Li_2CO_3 moistened with H_2O and covered with these reagents. Under similar conditions AcH gave a white product, not analyzed, while AcPh did not react. H. F. J.

Further studies in double-salt formation. I. The formation of copper sodium sulfate. R. M. Caven and W. Johnston. *J. Roy. Tech. Coll. Glasgow* No. **4**, 32–8 (1927); cf. *C. A.* **18**, 3329; **22**, 345, 715.—The influence of each single salt upon the solv. of the other is less at 25° than at 0°, although the double salt $CuSO_4.Na_2SO_4.2H_2O$ (1) is formed at 25° and not at 0°. The formation of complex ions in soln. is not always accompanied by the early appearance of the double salt if it is an endothermic compd.; e. g. in the case of (1) there is not heat energy enough to form the salt below 16.7°. Likewise, the salt $CuSO_4.Na_2SO_4.6H_2O$ which would be formed at a lower temp. is nonexistent. The non-formation of (1) at 0° is proved by the following expt.: (*a*) Na_2-$SO_4.10H_2O$ is crystd. (in a solid mass) at 0° from a (1) soln. satd at 38°, (*b*) from a (1) soln. formed at 10° and (*c*) when (1) is shaken with a little water at 0°. Na_2-$SO_4.10H_2O$ is crystd. first when equimol. solns. of the single salts are evapd. in vacuum at 17.5–18°, but when the mol. ratios of Na_2SO_4 to $CuSO_4$ were 1:1.05 (1) crystd.

first. **II. The formation of manganese, potassium and ammonium sulfates.** *Ibid* 38–41.—Cf. *C. A* **22,** 345. C. H. BADGER

The determination of the structure of hydrogen disulfide. Regarding the action of hydrogen disulfide on phosphorus. III. Compounds. JACOB DODONOV AND HERMAN MEDOX. *Ber* **61B,** 1767–70(1928).—Attempts at detg. the structure of H_2S_2 by treatment with PPh_3 yielded only $(C_6H_5)_3PS$ and H_2S, showing that triamylphosphines and arsines are not so constituted as to hold 2 SH groups permanently. Expts. with PCl_3 yielded P_2S_5, PCl_3S and HCl according to the following reaction: $3H_2S_2 + 3PCl_3 \longrightarrow P_2S_5 + PCl_3S + 6HCl$. It is believed that the mechanism of the reaction is as follows: $PCl_3 + H_2S_2 \longrightarrow PCl_3(SH)_2$, the $PCl_3(SH)_2$ reacting in 2 ways to form $PS_2Cl + HCl$ and $PCl_3S + H_2S$ and finally the PS_2Cl reacting with H_2S to form P_2S_5 and HCl. The above reactions lead to the belief that the structure of H_2S_2 is similar to that of H_2O_2. B. E. ROETHELI

Preparation of cyanogen by wet method. CECILE NOIR AND TCHENG-DATCHANG. *Compt. rend.* **187,** 126–8(1928).—Analysis of gases produced by KCN on soln. of $CuSO_4$ gave $(CN)_2$ 62, CO_2 30, HCN 2.5–3 and air 5%. Imperfections in method of analysis have been found. A new detn. gave $(CN)_2$ 78, CO_2 20 and HCN 1–2%. In order to eliminate the CO_2 it is proposed to prepare directly CuCN from KCN and $CuSO_4$ previously reduced by $NaHSO_3$. The pptd. cyanide of Cu is filtered, washed and oxidized by $FeCl_3$ (heat). L. D. R.

Potassium ferro- and ferricyanides. S. H. C. BRIGGS. *J. Phys. Chem.* **32,** 1422 (1928).—Polemic against F. H. Getman (*C. A.* **22,** 1543). W. T. RICHARDS

The thiocyanates of bivalent platinum. A. A. GRINBERG. *Ann. inst. platine* (Leningrad) **1928,** No. 6, 122–77.—G. has prepd. and studied some of the complex thiocyanates of Pt, in particular compds. of the types $[Pt(NH_3)_2(SCN)_2]$, $[PtPy_2(SCN)_2]$, $[Pt en(SCN)_2]$ and some others. The action of NH_3 or of amines on $K_2[Pt(SCN)_4]$ leads under all conditions to the formation of compds. analogous to the salt of Peyronne, thus of *cis*-compds., confirming the rule of Peyronne. The *cis*-compds. yield under action of thiourea the tetrathiourea complexes in all cases tried, whereas *trans*-isomers give products in which only the acid radicals are substituted by thiourea. The rule of Kurnakov is thus fully confirmed. Heating of the tetraamine compds. does not yield *trans*-isomers throughout, as was suggested by Jörgensen, the acid radicals substituting to a larger extent the NH_3 mols. The *cis*-isomers $[Pt(NH_3)_2(SCN)_2]$ and $[PtPy_2(SCN)_2]$ are less stable than *trans*-compds. on heating in dry state as well as in soln., although there is no direct transformation of the less stable into the more stable configurations. Compds. of the type $[Pt(NH_3)_2(SCN)_2]$ are capable of further addn.; thus the *cis*-isomer yields the complex $[Pt(NH_3)_2SCN(SCNAg)]NO_3$, whereas the *trans*-isomer forms more complicated products with $AgNO_3$. Mol. wt. detns. in org. solvents revealed that no polymerization takes place, their difference being due to a true isomerism. Only the *cis*-$[PtPy_2(SCN)_2]$, when dissolved in $CHBr_3$, shows some assocn. but in acetone this compd. gives the normal mol. wt. G. shows further that the reaction of $[PtCl_4]$ and of $[Pt(SCN)_4]$ complexes leads to the formation of $Pt(SCN)_2$, the complex $[PtCl_2(SCN)_2]$ being quite unstable, whereas a similar reaction of $[Pt(NO_2)_4]$ yields the ion $[Pt(NO_2)_2(SCN)_2]$. G. discusses the theoretical interpretation of the cases of isomerism here studied and concludes that Werner's theory of complex Pt compds yields the best agreement with his exptl. data. G. B. KISTIAKOWSKY

Double salts of selenic acid. JULIUS MEYER AND WILLI AULICH. Breslau Univ. *Z. anorg. allgem. Chem.* **172,** 321–43(1928).—Continuation of the work of comparing complex selenates with complex sulfates. This paper deals with the behavior of the alkali and alk. earth selenates with water, their soly., hydrate formation, etc. To conc. aq. selenic acid 170°/20 mm. is best and on cooling $H_2SeO_4.H_2O$, m. 26°, colorless, crystallizes out. It may slowly decompose into H_2SeO_3. The acid was recrystd. and its purity established. By treating aq. suspensions of the carbonates of Na,K, Ca and Mg in excess with the selenic acid the corresponding normal salts were obtained. K_2SeO_4 was made from 500 g. K_2CO_3 and 750 g. $H_2SeO_4.H_2O$. Its soly. is 9 mols. at 20° and 9.9 mols at 100° in 100 mols of water. It has a small soly. coeff. $Na_2SeO_4.10H_2O$ is obtained below 45° and Na_2SeO_4 above that temp. Its soly. is 546 mols. $Na_2SeO_4.10H_2O$ at 25°, greater than that of the corresponding sulfate. The anhyd. salt is not hygroscopic. Its transition point is 31.8°. $MgSeO_4$.7, 6, 4, $1H_2O$ were obtained. $CaSeO_4.2H_2O$ gave a max. soly. at 18° of 8.1 mols. per 1000 mols. of water whereas the max soly. of the corresponding sulfate is at 38°. $CaSeO_4$.1.5, 1, 0.5 H_2O were also obtained. Generally speaking the simple selenates are more sol. than the corresponding sulfates. S. L. B. ETHERTON

Concerning tetraphosphorus triselenide and phosphorus sulfoselenides. JULIUS

MAI. *Ber.* **61B**, 1807-11(1928).—(I) P_4Se_3 was prepd. by heating Se with P in tetralin at 215-20°. The hot mixt. was filtered and on cooling prismatic crystals of P_4Se_3 sepd. out. The crystals had a d. of 1.31*, m. 242-243° and varied from yellow to red-orange in color. The yield obtained was about 1/3 the theoretical. The reaction can also be carried out in acetylene tetrachloride, however, with lower yields. Moist air attacked the P_4S_3 to form H_2Se. The P_4Se_3 is sol. in cold CS_2 and in boiling C_6H_6, $C_6H_5CH_3$, $CHCl_3$, CH_3COCH_3, CCl_4 and acetylene di- and trichloride. H_2O has little effect; H_2SO_4 dissolves it forming a green soln.; concd. HNO_3 oxidizes it readily; NaOH reacts with it to form Na_2Se and PH_3; it phosphoresces at 160° and more strongly at higher temps. (II) Phosphorus sulfoselenides. Substances believed to be P_4S_2Se (m. 186-87°) and P_4SSe (m. 217°) were prepd. from the elements. Mixts. of P_4S_3 and P_4Se_3 were made up to correspond to the same compds. and were found to have m. ps. of the same magnitude. It is concluded that the sulfoselenides reported are probably only isomorphic mixts. of P_4Se_3 and P_4S_3. B. E. ROETHELI

Silicic acids. ROBERT SCHWARZ. *Zement* **17**, 930-3(1928); cf. *C. A.* **22**, 4028.—Hydrated SiO_2 was prepd. by adding finely powdered $Na_xSi_yO_z$ to chilled 80% H_2SO_4 soln., stirring for 2-3 hrs. and pouring the mixt. into a large vol. of cold H_2O, filtering and washing thoroughly the easily sepd. ppt. When this hydrate is brought into equil. with H_2SO_4, breaks in the vapor-pressure curves occur at 23.06% and 13.03% H_2O corresponding well with H_2SiO_3 and $H_2Si_2O_5$, resp. Chiefly H_2SiO_3 results from the hydrolysis of SiF_4, $SiCl_4$, etc., in the cold. In alkali silicate solns. SiO_3^{-} and $Si_2O_5^{--}$ are in equil.—the formation of $Si_2O_5^{--}$ being favored with increasing H-ion concn. H. F. K.

Recent theories on the constitution of silicates. E. HERLINGER. Berlin-Dahlem. *Z. angew. Chem.* **41**, 488-92(1928).—Much light has been thrown on silicate structure by the study of model silicates, physical-chem. equil. relations, and Röntgenographic analysis. The value of each of these methods is discussed. Three general methods of viewing silicate structure are common. (1) A great many of them can be regarded as assembled structures comprised of small characteristic groups united in varied numerical relation. (2) The elements Si or O can be considered as the nuclei of complex radicals. (3) In the *aluminosilicates*, the Al atom is regarded as the nucleus about which large complexes can be constructed. H. STOERTZ

A method of separation of rhodium and iridium by alloying with bismuth. B. G. KARPOV. *Ann. inst. platine* (Leningrad) 1928, No. 6, 98-100.—K. suggests the following procedure: Raw concentrates contg. Ir, Rh, Pt, Au, Pd and other metals are alloyed with Ag and treated consecutively with HNO_3 and aqua regia. Insol. residues are alloyed with Bi in a reducing atm. (graphite crucible) at 1000° for 2-3 hrs. This alloy is treated with dil. HNO_3 and later with aqua regia (1:1), the insol. residue being weighed as Ir. The purity of the latter is tested by fusion with K pyrosulfate and a repeated alloying with Bi. From the filtrates of the Ag alloy Pt and Pd are sepd. by ordinary methods. Bi-alloy filtrate of HNO_3 is evapd., the residue dissolved in weak HCl and Bi pptd. as oxychloride. The filtrate is tested for Pt and Pd. The aqua regia filtrate is tested for Pt. Au and for traces of Ir. Finally, both solns. contg. Rh are united and Rh is pptd. with Zn. It is washed with HNO_3, alloyed with Ag and, on dissolving the latter in HNO_3, weighed. Examples of analysis show complete agreement of the suggested method with the older method of sepn by means of Pb. It is shown furthermore that the new method represents a considerable (30-40%) saving in working time. The saving is the larger, the larger is the ratio Ir:Rh in the raw materials. G. B. KISTIAKOWSKY

Some salts of uranium. ST. WEIL AND ST. ROZENBLUM. *Bull. trav. inst. pharm. Poland* No. 1, 1-10(11-12, French).—*Basic α-phenylcinchoninate of quadrivalent uranium*, $(C_9H_5NPhCOO)_2UO + 3H_2O$, was obtained in a hot alc. soln. of cinchophen and UCl_4 as a greenish brown powder. *Uranyl α-(carboxyhydroxyphenylcinchoninate*, $C_{17}H_9O_5N.UO_2 + 4H_2O$ was formed as a red ppt. from uranyl acetate and lithium α-salicylcinchoninate in aq. soln. *Basic α-(carboxyhydroxyphenyl)cinchoninate*, $C_{17}H_9O_5N.UO + H_2O$, greenish brown ppt. *Uranium sulfosalicylate*, $[C_6H_3(OH)(SO_3)(COO)]_2U$, green ppt. *Uranyl salicylate*, $[C_6H_4(OH)COO]_2.UO_2 + 5H_2O$, obtained from salicylic acid and uranyl acetate in a hot aq. soln., small needles of orange-rose color. *Uranium salicylate*, $C_6H_4\left\langle{O \atop COO}\right\rangle U + 4H_2O$. *Uranyl salt of guaiacol*, $[C_6H_4(OCH_3)O]_2.UO_2$, obtained from K salt of guaiacol and uranyl acetate in aq. soln. Brown ppt. *Basic β-naphthalenesulfonate of uranium*, $(C_{10}H_7SO_3)_2UO$, obtained from a hot alc. soln. of β-naphthalenesulfonic acid and UCl_4, acidified with HCl. Greenish ppt. *Uranyl p-aminobenzenearsonate*, $[NH_2$-

$C_6H_4.AsO(OH)O]_2UO_2 + H_2O$, obtained from Na *p*-aminobenzenearsonate (atoxyl) and uranyl acetate in aq. soln., red ppt., insol. in water. *Uranyl methylarsonate*, $CH_3.AsO_3.UO_2 + 1^1/_2H_2O$, yellow ppt. *Uranyl p-hydroxy-m-nitrobenzenearsonate*, $[(NO_2)(OH)C_6H_3.AsO(OH)O]_2.UO_2 + 2H_2O$, yellow powder. *Uranyl m-nitroarsanilate*, $[(NH_2)(NO_2).C_6H_3.AsO_3H]_2UO_2 + 2H_2O$, greenish yellow ppt. *Basic uranyl salt of dihydroxydiaminoarsenobenzene*, $[NH_2.C_6H_3.O.UO_2(OH)As]_2 + 5H_2O$, yellow powder.

7—ANALYTICAL CHEMISTRY

W. T. HALL

More accurate moisture determinations by rapid drying. S. H. MEIHUIZEN. *Chem. Weekblad* **25**, 494–5(1928).—It is shown from examples (milk powder, beet seed, tea) that for easily decomposing substances more accurate moisture figures can be obtained by rapid drying (15 to 20 min.) at 137° (cf. app. of Meihuizen, *Ibid* **20**, 529 (1923)) and using boiling xylene. B. J. C VAN DER HOEVEN

Simple method for determining the concentration of solutions. G. JAEGER. *Ber.* **61**, 1654–9(1928).—The index of refraction of a soln against air at a definite temp. is a phys. const. which can be easily measured If the effects of changes of concn. on this index are known, it is possible to estimate the concn. by measuring the index of refraction. Examples are explained, $CuSO_4$, NH_4Cl, HCl and urea solns being used. W T. H

Sampling churn-drill sludge at the Utah copper mine. L. S. BRECKON. *Eng. Mining J.* **126**, 491–2(1928).—Details are given for sampling low-grade porphyry ore body in which a variation of only a few hundredths of one per cent in the Cu content will be of considerable importance. The selection of the sample is made mechanically Details of interest to the mining engineer are given. W. T H

The use of photoelectric spectrophotometry in microanalysis. H. v. HALBAN AND E. ZIMPELMANN. *Z. Elektrochem.* **34**, 387–93(1928).—The app. and method of photoelec. spectrophotometry were previously described by v. H. and Geigel (cf C. A. **15**, 343) The method can be used for microanalysis if the substance to be detd (1) absorbs light strongly in some spectral region in which the absorption by all other substances present is relatively weak, (2) can be converted by quant. chem. reaction into a substance satisfying condition (1), or (3) can be converted into an insol. ppt which produces a turbidity and thereby increases the absorption of light. The application of the method is illustrated by 2 examples given in detail, namely the *detn of* Fe^{+++} by conversion to $Fe(CNS)_3$ and the *detn. of Ti* by pptn. as TiO_2. In 50 cc. of soln. 0.001 mg of Fe or 0.01 mg. of Ti can be detd. with an accuracy of 1% and 0.00002 mg of Fe or 0.0001 mg. of Ti can be detected. F. L. BROWNE

Chemical development and fixation of latent fingerprints. G. POPP. *Z. angew. Chem.* **41**, 1005–7(1928).—Latent fingerprints may be developed: (*a*) *Mechanically*—By dusting the suspected surface with fine powders, such as Al, soot, indigo, cinnabar, etc., using a soft brush to dust it off, fingerprints may be revealed, later transfers may be made with "adhesive foil" (plaster). These methods are applicable only to certain kinds of surfaces. (*b*) *Chemically*.—Since perspiration contains 0.5–1.5% of solid matter, with NaCl, urea, volatile fatty acids, albumin, cells from the epidermis, and perhaps fat it has been proposed to treat the suspected object with osmic acid, Sudan III, $HgNO_3$, $AgNO_3$, eosin, alcoholic fuchsin, alcoholic tannin, gaseous HF, thiosulfates, etc. For slightly colored or uncolored paper, dilute ink may be used. Far better treatment is with cool I-vapor, which is absorbed better by the fat, urea, etc., than by the surface examd., developing a brown color; treatment must stop as soon as the object itself begins to show a brown color. Heretofore such I-images have had to be photographed quickly. Efforts to fix them with gallic and tannic acids, $AgC_2H_3O_2$, HgCl and subsequent action of H_2S or $(NH_4)_2S$ have not been satisfactory. Paper with the I-image may be preserved between plates of glass temporarily, thus preventing volatilization. The use of reagents to convert the I into "starch-iodide," HgI_2, TlI, AgI, K_2PtI_6 and PdI_2 showed that $PdCl_2$ soln. (1:1000) gave the best results. Float the

paper or dip it into the dil. soln., and then wash thoroughly. To retain ink marks on the paper add alum or tannin to the reagent. The fingerprint record so made can be removed with dil. NH_4OH. If the reagent be made by dissolving $PdCl_2$ in HCl, with gentle heating, it must be neutralized with soda before using. W. C. EBAUGH

Use of one-color indicators in the double-cup colorimeter. HANS KROEPELIN. Univ. Erlangen. *Biochem. Z.* **198,** 225–32(1928).—Instructions are given for the use of the double-cup colorimeter for p_H detns.; also data for the use of indicators of the nitrophenol series. S. MORGULIS

Anthocyanin as an indicator in acidimetry. V. MATULA. *Časopis Československého Lékárnictva* **7,** 121–3(1927); cf. *C. A.* **18,** 2481.—M. examd. the gradations in color in anthocyanin solns. of p_H 1 to 13. The change in color is marked near the neutralization point, a bluish gray color corresponding to p_H 7. M. concludes that anthocyanin from red cabbage may be used as an indicator for ordinary detn. of acids and bases, when these are not too dil. WILLIAM J. HUSA

Contributions to the systematic knowledge of indicators. XI. Phenolphthalein and its derivatives. A. THIEL AND R. DIEHL. *Sitzungsber. Ges. Beförderung gesamt. Naturwissenschaften Marburg* **62,** 472–546(1927).—The color change of phenolphthalein is best explained by Acree's theory which assumes that the phenolic residue assumes a quinoidal structure and there is also an ionizable phenolic group in the *p*-position to the central C atom. The color change takes place in accordance with Pfeiffer's theory of halochromic compds. The purpose of the work here described was to bring together, as far as possible, all the experimentally detd. facts in order to decide the truth concerning some theoretical points of view and to develop methods for estg. the equil in alk. solns. The absorption curves of the various indicators were detd. as well as the end point curves by means of the König-Martens spectral-photometer, using a 50 candle power lamp, at 8 volts. With respect to the influence of substituents, it was found that the chlorophenolphthaleins showed additive properties. The position of the maxima for the addition of 1 Cl group in the first phenol group can be computed on the assumption that $\Delta\lambda = 4m\mu$ and in the second phenol group $\Delta\lambda = 10m\mu$. The effect of adding an NH_2 group is greater. In this case $\Delta\lambda = 22m\mu$ but the effect is not quite 4 times as great when 4 NH_2 groups are added. The reciprocal action of both phenolic groups is necessary to accomplish the deep color in alk. solns. With the nitrophenolphthaleins the conditions are otherwise. The following substances were studied in this investigation, some of them being prepared pure for the first time. *Phenolphthalein, 3'-chlorophenolphthalein, o chlorophenol, 3',3"-dichlorophenolphthalein, 3',5'-dichlorophenolphthalein, 3',5',3"-trichlorophenolphthalein, 3',5',3",5"-tetrachlorophenolphthalein, 3',5',-3",5"-tetrabromophenolphthalein, tetrabromophthalein oxime, 3',5',3",5"-tetrabromophenolphthalein ethyl ester, 3'-nitrophenolphthalein, 2-[3'-nitro-4'-hydroxybenzoyl]benzoic acid, 3',3"-dinitrophenolphthalein, 3',5'-dinitrophenolphthalein, 2-[4'-hydroxydinitro-4'-hydroxybenzoyl]-benzoic acid, 3',5',3"-trinitrophenolphthalein, 3',5',3",5"-tetranitrophenolphthalein, 3' aminophenolphthalein, 3',3"-diaminophenolphthalein, 3,5'-diaminophenolphthalein, 3',5',3"-triaminophenolphthalein, 3',5',3",3"-tetraaminophenolphthalein, phenolphthalein 4"-methyl ether, 3'-nitrophenolphthalein 4"-methyl ether, 2-nitrophenol, 2-6-dinitrophenol, phenol-4,5,6,7-tetrachlorophthalein, thymolphthalein, bromophenol blue, brilliant green, phenolphthalein oxime, 3-aminophenolphthalein 4"-methyl ether, 3'-aminophenolphthalein 4"-methyl ether oxime, phenolphthalein 4"-methyl ether oxime, 3'-nitrophenolphthalein oxime, 3',5'-dinitrophenolphthalein oxime.* G. SCHWOCH

Colorimetric methods in the foundry laboratory. HUGO FREUND. *Giesserei* **15,** 133 4(1928); cf. *C A.* **22,** 2337.—Optical-analytical methods, which have been in use in smelting and steel labs, are recommended for use in foundry labs. The colorimeter is described. Customary methods for detg. the combined C in pig and cast Fe, the Mn, the Cu and the Ti are given. J. BALOZIAN

Detection of arsenic in cadavers. G. POPP. *Z. angew. Chem.* **41,** 856–8(1928).—An interesting account concerning some toxicological forensic work in connection with the trial of the German poisoner Hopf. The bones of a cremated corpse will show probably only about 0.1% of the total As contained in the human body at the time of death. From the bone powder, all the As can be extd. by leaching with dil. NaOH. W. T. H.

Colloidal arsenic trioxide in the arsenic determination. E. G. MAHIN AND A. F. DOYLE. Univ. Notre Dame. *Proc. Indiana Acad. Sci.* **37,** 269–72(1927).—In detg. the As content of insecticides according to the directions of the Assoc. Offic. Agr. Chemists, Gooch's method is recommended to reduce the As to the tervalent condition by treatment with KI in acid soln. Usually a brownish color develops first which is due to dissolved I_2. The directions call for the boiling off of the liberated I_2 but if the boil-
